THE CLASSIFICATION AND DIAGNOSTIC GUIDES OF INTESTINAL OBSTRUCTION.*

H. TUHOLSKE, M.D.
Professor Surgery Medical Department, Washington University;
Surgeon to Polyclinic Hospital; Surgeon in Chief
of the Jewish Hospital.
ST. LOUIS.

VARIETIES OF ILEUS.

The medical writers of classical antiquity, beginning with Hippocrates, applied the term ileus to pathologic conditions in the abdomen characterized by meteorism, pain, vomiting of bilious feculent matter and interference with the passage of feces and flatus. The essential cause was believed to be inflammation of the intestine or of the peritoneum and "*ex inflammatione resiccatur intestinum et constipatur ut neque flatum neque alimenta transmittat. Venter durus fit et vomit interdum imprimis quidum pituitosa deinde vero biliosa, tandem etiam stercus.*"[1] According to Galen, inflammation produces a cessation of peristalsis, absolute constipation, or antiperistalsis with vomiting of fecal matter, or in brief, the disease called ileus. All through the middle ages the influence of the teaching of Hippocrates and Galen remained dominant. With the development of the anatomic school in the fifteenth and sixteenth centuries and the more careful postmortem examinations, varying anatomic conditions were recognized as the causes of ileus; so that at the close of the eighteenth century most forms of intestinal occlusions, as by invagination, compression by abdominal tumors, by pseudoligaments or omental bands, by gallstones and enteroliths, by diverticula of congenital origin and by slits or openings in the mesentery or omentum, were well known to the anatomists and pathologists. But the knowledge of these pathologic conditions failed to make any great impression on the physicians of that period, who saw in these anatomic conditions, not the causes, but accidental results of peritonitis, hardly ever absent in their postmortem examinations, and brought about by antiperistalsis or by a special quantity or quality of gas formation and retention. Ileus qualified by the adjective inflammatorius remained the collective term for the symptoms of the various anatomic conditions of intestinal strangulation and occlusion, all of them essentially of inflammatory origin. It was the zenith of the period of theoretical speculation of the arm-chair philosopher who, without the basis of exact observation, influenced and controlled medical thought and practice. To the ileus inflammatorius was now opposed the *ileus nervosus* by the neuropathologists, and we read of the ileus spasmodicus, *ileus paralyticus*, and *ileus antiperistalticus*, as a result of a pathologic innervation of the intestinal tract. It was only after the first quarter of the last century that the earnest insistence of pathologists, comparing the observations of the postmortem room with bed-side experience, pointed out the causal connection between anatomic findings and clinical symptoms without the injection of fanciful and speculative theories, bringing light into this most confusing subject and making the knowledge so gained available for practical endeavor.

CLASSIFICATION.

The diagnosis of ileus is about as definite of pathologic conditions as is the diagnosis of jaundice or of hematemesis. To get at the varying and divergent pathologic conditions characterized by a combination of symptoms of almost bewildering uniformity, the need of an unobjectionable classification is apparent. We, therefore, speak of first, congenital, and second, of acquired ileus. Congenital ileus offers scarcely a diagnostic difficulty of practical value and requires only casual mention here. Obstruction of the bowels in the new-born most frequently depends on an agenesis of the anus, or upon an atresia of the anus, rectum or colon. The occurrence of atresiæ in certain places of predilection in the ileum, jejunum and duodenum, due to faulty development or fetal peritonitis, is very rare, and still rarer, the occasion for a diagnosis. Acquired ileus may occur from the loss of propelling power in the intestinal musculature, or from a mechanical closure of the canal,[2] hence the division into, first, dynamic or paralytic, and, second, mechanical ileus. Dynamic ileus is the outcome of a paresis or paralysis of a piece of intestine of greater or less extent. It may be the result of inflammation, of mechanical or chemical irritation of the peritoneum, of bacterial infection processes in the intestinal canal not producing peritonitis, but hyperdistension from gas accumulation, or of embolism or thrombosis of the superior mesenteric artery or vein; or, finally, of nerve disturbances, as after anatomic changes in the central nervous system, producing loss of power in the abdominal muscles, interfering with the abdominal press, allowing an accumulation of flatus and fecal matter and producing hyperdistension. In addition, there is a variety of temporary character and one offering no difficulties in the way of differential diagnosis, viz.: reflex paresis after compression of a testicle in the inguinal canal and after operations for hemorrhoids and in hysteria. It might appear that ileus in connection with peritonitis might be omitted from consideration at this point. It is necessary, though, in an acute case of ileus and peritonitis, to determine whether ileus be the cause or the effect of the peritonitis and, if the latter, what is the cause of the peritonitis. Mechanical and chemical irritation are unquestionably the causes of dynamic ileus; it is not rare after extensive operations about the mesentery, after operations in which raw surfaces of the peritoneum remain and after a vigorous toilet of the peritoneum; it was frequent during the period of antiseptic abdominal surgery under carbolic spray and the use of antiseptics in the peritoneal cavity. There occurred distension of the abdomen, meteorism, inability to pass feces or flatus, vomiting and restlessness without pain or tenderness on pressure, without peritonitis, the condition well described as "peritonism." Sometimes hyperdistension in the intestine would produce venous stasis, serous infiltration of the intestinal wall,[3] at last permeability to and infection by the colon bacillus, when the whole dire picture of peritonitis would follow. More often ileus was arrested before it reached that stage.[4]

Ileus, the result of embolism of the superior mesenteric artery, is rare; comparatively few cases have been carefully observed and reported. This may excuse my inserting here a case in my own care three years ago.

History.—Physician, well nourished, aged 50, seen in consultation four days after occurrence of attack, had been a generous liver, had suffered many attacks of abdominal pain after indiscretions in diet; but believed he had never had appendicitis. He had been afflicted with inflammatory rheumatism and had recovered from last attack four weeks ago. He was taken four days ago with pain in the abdomen, severest about the umbilicus, accompanied by great prostration amounting to shock, and by vomiting. He was relieved by hypodermic injection of one-fourth grain of morphia; was better next day, but suffered an uncomfortable distension of his bowels, thought to be due to the morphia. Distension increased; patient took laxative without effect; at the end of the second day there was more vomiting and no flatus or stool. Temperature 99 F., pulse 110. On the third day the patient was rapidly getting worse; he had a large foul passage from bowel consisting entirely of black, tarry, putrid-smelling blood. Distension was greater and vomiting more frequent; abdomen tender on the left side.

Examination.—I found the pulse 120 to 130, temperature 101 F., pulse feeble and small, face pale, and anxious and clammy, barrel-shaped distension of the abdomen with well-marked dulness in the left side and considerable resistance; urine scanty, containing indican; heart sounds weak and mitral br[illegible]

Diagnosis.—Obstruction of the bowel. Because of the firm, well-marked swelling on the left side, we thought of volvulus of the sigmoid colon, of intussusception, or of embolism of the superior mesenteric artery. In the absence of straining at stool and of frequent bloody and mucous discharges, invagination discarded; patient being able to hold 2½ quarts of fluid injection, sigmoid torsion was thought impossible, hence the probable diagnosis of embolism of the superior mesenteric artery. Patient was made acquainted with the probable diagnosis.

Operation.—A laparotomy was done the same evening. Incision in and through the left semilunar line over the swelling. Very foul, bloody, serous discharge escaped on opening the peritoneum, and the involved bowel at once presented. A piece of ileum, rather more than three feet in length, dark brown, blackish in color, sodden, rigid and friable, was drawn out of the cavity; resected, and both ends fastened to parietal wound. Patient returned to bed, regained consciousness, though pulseless; never reacted. Death eight hours after operation.

Postmortem.—Examination showed embolus one and a half inches long in the superior mesenteric artery, and intestinal infarction of great extent. No other cause of obstruction; heart showed mitral insufficiency, and some fresh vegetations on valves. This was, therefore, an undoubted case of dynamic ileus due to embolism of the superior mesenteric artery.

For the elucidation of the interesting question, why after embolism of the superior mesenteric artery there occurs infarction of the intestine and gangrene when there exists apparently such complete collateral arterial circulation, I wish to quote from an interesting paper by Deckart.[5] The pathologic findings, after sudden closure of the superior mesenteric artery, were in all cases, except in three by Virchow, Karcher and Chene, hemorrhagic infarction of the section of intestine depending for its blood supply on the superior mesenteric artery, i. e., from the lower end of the duodenum to the colon transversum. Cohnheim, who took much interest in the question, could offer no satisfactory explanation, since the superior mesenteric artery is no anatomic end artery and its free arterial anastomoses show clearly in the normal mesentery. He, therefore, believed that such infarction of the intestine could only result if not only the trunk or larger branches, but the smallest branches be closed; in other words, unless the mesenteric artery has been first transformed into an end artery. He thought this at the time of the case of Ponfick, in which smaller particles from the embolus had plugged a great many smaller branches. This explanation is insufficient, since infarction occurs in cases in which the smaller arteries remain entirely unobstructed. The question was solved theoretically and experimentally, by Faber and Litten. Faber pointed out the very long distance which the blood in the collateral routes would have to traverse; the infarction is complete before that can be accomplished. The correctness of his supposition was proved by the experiments of Litten on animals. From the moment of the ligation of the superior mesenteric artery all circulation in the territory supplied by it was arrested and could not by any means be re-established. The pressure in the peripheral arteries was equal to zero; it behaved, therefore, like an end artery, and after its closure infarction of the intestine followed the reflux of the venous blood. Other points of interest in this article merit its careful perusal; also that of Borseky,[6] and that of Lillington.[7]

THE CLASSIFICATION COMMON IN THE TEXT-BOOKS.

The classification of mechanical ileus on an anatomic and clinical basis is the usual one and one which recurs in most text-books, whether treated of in works on surgery or on internal medicine. Let me select for illustration from some of the best sources. Leichtenstern[8] in his classical and exhaustive treatise in Ziemssen's Encyclopedia, gives us the following:

> The anatomic basis of occlusion or narrowing of the intestinal canal. *First,* causes which by pressure from without close the lumen, and to this belongs incarceration of the intestine in openings or slits, normal or acquired, in the omentum and the mesentery, and the fossæ for internal herniæ, strangulations by pseudoligaments, appendix and Meckel's diverticulum, compression by tumors, by the mesentery and dislodged viscera. We count here also torsion and knottings, since occlusion is here produced by pressure which the intestinal loops exercise on each other. *Second,* causes which pro-

> duce obstruction of the lumen by plugging: (*a*) Causes which are not in continuity with the intestinal wall, as gallstone, enteroliths, foreign bodies and *fecal* masses. (*b*) Causes which *are in* continuity with the intestinal wall, spread and obturate, as neoplasms. (*c*) Obturation by the intestine itself, as invagination. *Third*, causes which originate in the intestinal wall, or affect them by narrowing of the lumen *in ring* form, or by angulation or traction, as strictures and flexions; to it belong those originating in chronic peritonitis, the cicatricial stenoses and neoplasms, by infiltrating and contracting the intestinal wall. On the clinical basis: *First*, symptoms of total and complete occlusions and the symptoms of partially impeded permeability, and under this heading, causes which produce acute occlusion sudden, total and complete, to which belong incarceration, strangulation, torsion, sometimes gallstones. *Secondly*, those which are acute, but do not produce total occlusion at once, but which later result in it, as intussusception, incarcerations and acute incomplete compressions. *Finally*, causes which originate slowly and, as a rule, produce symptoms of disturbed permeability for a longer time until there occurs a sudden occlusion, or without it, peritonitis and perforation, and to this belong the causes by stenoses, by strictures, neoplasms and chronic peritonitis, the compression of gradually growing tumors, and the majority of obturations by stones and fecal impaction.

This very comprehensive classification, logical in its way, lacks in distinctness and, therefore, usefulness, while detracting nothing from the universally acknowledged most authoritative treatise for which it forms the basis.

Clear and concise on the same general plan is the classification of Treves.[9] He says:

> The classification of intestinal obstruction is most conveniently founded on the basis of morbid anatomy, and may be tabulated as follows: Strangulations by bands and through apertures; volvulus and intussusception, stricture, obstruction by tumors and foreign substances within the bowel, by pressure of tumors external to the bowel, and by fecal accumulation (page 601). From a clinical point of view, cases of intestinal obstruction may be conveniently divided into three classes: Acute obstruction, chronic obstruction, and cases in which symptoms of acute obstruction supervene on those indicative of chronic obstruction.

A REARRANGED CLASSIFICATION.

The above classification, with which writers in the main agree and which physicians and surgeons use as the basis for diagnostic differentiation, may, in my opinion, be reconstructed in the light of the observations and experiments of latest years, as shown in the writings and experiments of Wahl, Manteufel, Kader, Nothnagel, Senn, Schlange, Zeidler, Deckart and others. The experiments of Kader (as quoted by Zeidler[10]), show that all forms of mechanical ileus may be divided, from an important diagnostic and therapeutic view, into two divisions; into the obstruction due to strangulation, in which the intestine and its mesentery as well are strangulated and the circulation of both intestine and mesentery is interfered with, endangering the vitality of the obstructed section; and into obturation, in which the lumen of the bowel, without involvement of the mesentery, is interfered with and in which the subsequent changes are, in the main, due to stagnation of the intestinal contents. Strangulation of an external hernia may be taken as a paradigm of the first variety. The strangulating agents are of several kinds. Peritoneal adhesions may result in the formation of bands or strings, round, flat, short or long, which may connect one loop of intestine with another, or with the mesentery or parietal peritoneum. Like a band in effect is Meckel's diverticulum, which forms a finger-like projection from the ileum, usually within eighteen inches of the ileocecal valve. The end, though commonly free, may be attached to the abdominal wall near the navel or to the mesentery, and a ring is thus formed through which the bowel may pass.[11] From the end of the appendix and fallopian tubes similar bands may arise. Foramina in the omentum, of congenital origin, splits in the omentum or mesentery, from trauma or in broad peritoneal adhesions, may incarcerate a piece of bowel, as has also been observed, although rarely, in a split of the suspensory ligament of the liver, and in the broad ligament of the uterus. An important contingent is furnished by the herniæ retroperitoneales of Treitz, herniæ into the duodenojejunal, duodenal, pericecal and intersigmoid fossæ and through the foramen of Winslow into the bursa omentalis, as quoted *in extenso* by Rokitansky[12] from Treitz's article.

As in the external, *the ileum is most frequently concerned* in internal hernias. Much more frequently is the sigmoid colon concerned in a form of strangulation known as volvulus, or axial torsion. According to Rokitansky,[13] a piece of bowel may turn on its own axis and after a half turn the lumen may be occluded, or it may turn around the mesentery as its axis, or its axis may be both mesentery and colon, and finally around this loop another loop may become twisted. A long flexure with a long mesentery, so narrow that the mesenteric ends of the loop are close together, forms a favorable condition for torsion when the dependent loop is filled with feces. Sometimes a violent exertion or shaking is the determining cause. According to the observations of Lawson obturation occurs on a twist on its axis of 180°, strangulation only after 270°. Torsion may occur in the small intestine, with an abnormally long mesentery, very narrow at its root. Such condition may be congenital, or the result of inflammation, or of the fixation of a loop for a long time in an external hernial sac.

OBTURATION.

The clearest forms of obstruction by obturation are those produced by gallstones, intestinal concretions, foreign bodies and fecal impactions. Gallstones, causing obstruction, reach the duodenum or colon from the gallbladder through an opening, the result of adhesions and ulceration. Abercrombie,[14] however, mentions a case where at the postmortem examination of a patient, from whom a gallstone four inches by three and a half inches had been removed from the ileum during life, the common bile duct was still large enough to readily admit his index finger. The gallstone may become fixed in any part of the small intestine, rarely in the middle of the ileum, more frequently in the duodenum and jejunum, most frequently at the lowest part of the ileum, from one to two inches above the ileocecal valve. The reason for this appears to lie in the lessening of the lumen of the ileum as it approaches the cecum and in the fixation of the lowest part of the ileum by a short mesentery. While impaction of a gallstone in the ileum, as a rule, gives rise to most acute symptoms, many cases are recorded where in the colon and rectum, although of such wide difference as to size and structure, likewise threatening symptoms were observed. Sometimes small stones give rise to symptoms of obstruction (in a case of Israel, a stone one inch in its greatest diameter), initiated by reflex muscular spasms. Enteroliths are very rare and form gradually in the large intestine; a foreign body forms the nucleus for deposits of phosphate and ammonia-phosphate of lime. Foreign bodies getting into the small intestine most frequently, pass, unless they encounter some stricture or unless, on account of their own contour, they injure the mucous membrane and produce swelling, penetration, etc. Fecal accumulation occurs as the result of habitual obstipation and neglect in patients with mental depression, melancholia, or in imbeciles, or after the use of opium or astringents in supposed diarrhea and dysentery, the result of constipation. This is more frequent in the female.

[14] Abercrombie: By Zeidler.

A prolific cause of obstruction is stricture. Strictures of the intestine are either cicatricial or malignant. The cicatricial are the result of tubercular, syphilitic, dysenteric, stercoraceous, or typhoid ulceration, or are occasionally congenital or form after separation of a gangrenous intussusception, or from lesions following strangulation of the bowels in hernia. The tubercular stricture is most common in the neighborhood of the ileocecal valve, the dysenteric in the colon, the syphilitic in the rectum. The frequency of dysenteric stricture is much overrated, while that of the tubercular much underrated.

Malignant stricture is due to the growth in the bowel of a cylindrical epithelioma, the only primary form of cancer to which the intestine would appear liable (Treves). It produces a tough, ring-like stricture; the outer surface of the gut at the seat of stricture is often sharply constricted, while, in the interior, the growth assumes an annular outline. Sarcoma of the bowel rarely produces obstruction. Schlange[15] cites a case, however, in which symptoms of acute obstruction resulted from a sarcoma growing from a comparatively small pedicle of the submucosa, twisting the bowel and becoming impacted in the pelvis. Adenomatous and polypoid tumors may produce obstruction. An important rôle in the development of obstruction of the bowel is played by the results of chronic or circumscribed peritonitis, in the matting together of the intestines, their kinkings, angulations and flexions. Treves admirably described these often complicated conditions.

INTUSSUSCEPTION.

Intussusception is the most frequent cause of ileus. The general anatomic features need no description in this place. In spite of its importance and frequency, I have placed it last, because in it strangulation and obturation are almost inseparably bound with each other. The condition and behavior of the mesentery determine the picture of strangulation or its absence. Rokitansky says:

> Between the intussusception and the intussuscipiens lies the mesentery belonging to it, folded into a cone, the apex of which is at the fore end of the intussusception and the base at the entrance of the intussusceptum into its sheath. By traction on the intussusceptum this becomes curved with the concavity forward at the mesenteric attachment, and the whole involved loop is drawn toward the vertebral column.

In the invaginated mesentery the signs of interference with its circulation depend on the extent and rapidity of the development of invagination. The acuity of the symptoms is always proportionate to the severity of the strangulation of the mesentery. In the most violent cases the arterial and venous circulation is interrupted and gangrene is the inevitable consequence. The dangers in the acute stages are gangrene and perforation at the neck of the invagination, of the chronic, death from exhaustion and stercoremia. In the rare cases of cure by sloughing, obstruction from cicatricial stenosis threatens the life of the patient later.

According to the site of the invagination we speak of enteric or ileal, of colic, of ileocecal and ileocolic invagination. According to Leichtenstern the ileocecal is by far the most common, 44 per cent.; the enteric, 30 per cent.; the colic, 18 per cent.; the ileocolic, 8 per cent. Wiggins found the frequency of the ileocecal variety as high as 89 per cent in 103 cases. Ileocecal invagination occurs most frequently in children. Seventy per cent. of cases in children are of that variety. Ileal invaginations are most frequent in the adult and are chiefly found in the lower part of the ileum.[16]

SYMPTOMATOLOGY OF ILEUS.

The classical descriptions of the symptoms of acute and chronic obstruction, which abound in our text books, invite repetition or imitation; but by the division of ileus into a dynamic, strangulation and obturation variety, I have created for myself a great difficulty. The old picture does not quite fit. Dynamic ileus shares with the mechanical varieties the cardinal symptoms of interference with the passage of feces and flatus, of meteorism, of vomiting and pain; but it takes cognizance of peritonitis as a cause of ileus, which opens the scene, while in the other it closes it. Furthermore, the dynamic variety embraces forms so temporary and mild, that the paresis of the bowel with its distension and meteorism may disappear before fecal vomiting occurs; while on the other hand, in the most acute form due to embolism of the superior mesenteric artery, the patient may succumb to gangrene and stercoremia before peritonitis is fully developed. An aggravated case of ileus, whether dynamic or mechanical, is characterized by constipation more or less complete, by accumulations from excessive formation and retention of intestinal gases, by pain and vomiting, at first bilious, finally stercoraceous, by prostration, and scanty urine, most generally containing indican.

Of the symptoms above enumerated, perhaps the fecal vomiting and indicanuria deserve further notice. It is now generally accepted that fecal vomiting is not due to antiperistalsis, but to a "running over of the intestinal contents upward" by regurgitation of the stagnant, putrefying, feculent fluids. I can not refrain from considering the question not entirely settled; my own observations and experience and the interesting experiments reviewed in the *Grenzgebiete*, 1902, by Mühsam,[17] leave this particular phenomenon *sub judice*. The condition of the urine in patients with ileus has received much study. Carter called attention to the presence of indican in the urine in intestinal occlusions. According to Taffen, Orthweiler and Nothnagel's experiments, increased indigo secretion requires the presence of sufficient albuminoid material in a state of intense putridity and the absorption of formed indol. The results of these experiments show that the formation of indican began after twenty-four hours and reached its maximum on the third day. It is absent or present in very small quantities in occlusions of the large intestine. In diffuse peritonitis it is generally present in large quantities. With the above named symptoms present no experienced physician or surgeon will find much difficulty in making the diagnosis of obstruction. The difficulties begin when we try to differentiate and to find the underlying anatomic conditions and site. The present postulate insisted on by Wahl requires a diagnosis of the site and the nature of the obstruction. Desirable as this is, it will often be found impossible and this surely, in spite of the careful study of the history and local conditions, when in the later stages peritonitis blurs all signs. A knowledge of the possible anatomic conditions, a careful study of the history of the case and local examination, by palpation, auscultation and percussion will help greatly, especially when we shall feel the cultivation and application of these methods to be as essential and productive of results here as in determining the physical signs of chest conditions. Clinical observations and experiments allow of the recognition of certain modifications of form and motility. In circumscribed peritonitis the affected section becomes distended and paretic; in acute diffuse septic peritonitis the distension may reach the limits of the cavity, the intestinal tract is paralyzed and peristalsis abolished. In strangulation the involved loop is paralyzed, distended and fixed and the afferent gut, in the first days at least, but little affected. The strangulation agency fixes the loop *in loco*. Distension, with loss of peristalsis, may develop in from four to eight hours; the circulation is seriously compromised. The fixed, distended, paralyzed loop, devoid of peristalsis, produces asymmetry of the abdomen noticeable by inspection. (Zeidler[10]). In obturation, the circulation in the intestinal wall is but little affected in the beginning, since the mesentery is not involved. Dilatation of the proximal intestinal section occurs gradually and peristalsis is often increased above the point of obstruction. There is no fixed paralytic loop. The distal end of the intestine is empty. The recognition of stiffening or peristaltic loops above the point of obstruction is significant of obturation. When, later, peritonitis is added, all peristalsis ceases and the picture becomes obscure.

DIAGNOSIS.

Dynamic Ileus.—The diagnosis of dynamic ileus concerns itself first with the question of peritonitis, and, if peritonitis be found, with its cause. If we find distension and paralysis of the intestine as evidenced by absence of peristalsis and want of contouration of intestinal loops; if the abdomen is tender on pressure and the patient lies on his back afraid to move, the diaphragmatic descent interfered with, and breathing labored, hurried and thoracic; if there be indican in the urine and the urine scanty, the pulse rapid and feeble, the diagnosis of peritonitis is easily made. Temperature is not a reliable diagnostic sign. The answer to the question as to its cause will be reached by inquiring: Was there an appendicitis, a leaky tube, an ulcer in the stomach or duodenum and perforation; was there typhoid fever? The embolic form is dynamic; if the onset was sudden, accompanied by pain and prostration with obstruction to feces and flatus but the discharge of large, putrid, bloody, tarry stools with a demonstrable exudate in the flanks and if endocardial heart lesions can be made out, a probable diagnosis of embolism of the superior mesenteric artery with infarction of the intestine may be arrived at. The varieties of dynamic ileus, due to mechanical and chemical irritation or of nervous origin, will be diagnosed by a careful consideration of the history, by the mild general and generally temporary symptoms, and the absence of fixed, immobile loops of paralyzed intestine and by the absence of much tenderness on pressure.

Strangulation Ileus.—Having in a given case eliminated the probability of paralytic ileus and decided that we are dealing with a mechanical obstruction not congenital, the question of strangulation or obturation presents itself. The paradigm, as mentioned above, of a strangulation is the strangulated external hernia, of a strangulation of the bowel and its mesentery. The picture of strangulation is a striking one. A person, apparently in good health, is suddenly taken with a violent pain in the abdomen, accompanied by collapse, nausea, vomiting. To this is very soon added the urgent desire to relieve the bowel of feces and flatus. There is at once the feeling of serious illness, of great anxiety and restlessness. Unrelieved, these symptoms are joined by that of intestinal distension. The pain generally felt about the navel is not significant of locality; it is infinitely more severe in the thin, highly innervated, small intestine than in the large. The initial vomiting with singultus is reflex and begins with the occurrence of strangulation, and with it also come the signs of collapse, the incarceration collapse, and almost anuria from reduction of the arterial pressure. The vomiting in later stages is due to distension and gas accumulation, the stercoremia to toxic absorption or septic infection after permeability of the intestinal wall has become established. After a few hours, perhaps from eight to twelve, the results of the circulatory interference become noticeable; the strangulated section of bowel becomes distended, fixed and paralyzed, and in favorable subjects, seen early, produces asymmetery of the abdomen and can be made out by inspection and palpation. The afferent loop is not yet appreciably distended; peristalsis may be present. All symptoms increase in severity. To the distension of the strangulated part distension of the proximal loops is added and general greater distension. The efferent intestine has been emptied of fluid and gaseous contents and remains collapsed. To the initial shock, the incarceration shock, after the second day are added symptoms of permeability, due to changed condition of the gut at the point of strangulation, and symptoms of general peritonitis develop; the vomiting increases in frequency and the putrid feculent intestinal contents are emitted by regurgitation. The abdomen is tense and tender on pressure, peristalsis everywhere absent; to the signs of stercoremia are added those of septic infection. With the occurrence of gangrene the pain grows less and the patient enters the stage of lethal collapse. The occurrence of perforation may somewhat modify the latter symptoms. If we add to these local symptoms those of the general condition, the rapid, feeble, compressible pulse, the anxious expression of countenance, the pale or cyanotic color, the sunken eye, the pointed nose, the skin cold, clammy and empty of blood, we get the appalling picture characteristic of the result of sudden strangulation. While from such a picture the diagnosis of strangulation ileus will not be difficult, the anatomic diagnosis of the site and nature of the strangulation will barely be one of probability. During the first day, however, in band or twist strangulation, the fixed, dilated, paralyzed loop will give valuable hints.

Obturation Ileus.—In the main, the general symptoms of obturation bear a great resemblance to those of strangulation; a closer investigation, however, will disclose quite a difference in their character. Let me consider them singly. Vomiting in strangulation is present at the beginning, is initial and reflex; in obturation it is rarely present early; but in later stages, after distension and overfilling of the canal above the point of obstruction, it is always present and soon becomes stercoraceous. This latter symptom is more definite in obturation than in strangulation in which the initial vomiting empties the canal above the point of obstruction and prevents over-filling to a great extent, and in which death often takes place before an accumulation of foul and putrid masses can occur. Obstruction to the passage of feces and gas, absolute in strangulation, is often incomplete and intermittent in obturation, depending on the character and extent of the obturating cause. The pain in strangulation is severe and continuous from the beginning; in obturation it may be severe but it is of a different character; it is periodical and intermittent and accompanies the peristaltic contractions in the loop proximal to the obstruction; it is of spastic, tetanic character. The incarceration shock, so profound in strangulations, is absent in obturations. The pain may be severe, but the rapid loss of strength and the feeble heart action of strangulation are absent; the pain may continue for days and days, but the heart remains fairly strong; it is only after the appearance of stercoremia and septic infection, that the natural exhaustion due to suffering and sleeplessness and starvation, gives way to collapse. Meteorism is present, but not localized in a loop, as in strangulation. The principal cause of meteorism, according to Kader and others, is to be found in the circulatory disturbance of the affected loop and the immediate disproportion between gas resorption and accumulation. In obturation it accumulates in the canal above the point of obstruction, peristalsis is marked and may indicate the point of obstruction. In the intensity and character of the peristalsis, we find important signs of obstruction, and especially in cases where an acute is grafted on a chronic stenosis, obstruction, etc. In those cases the hypertrophy of the muscularis gives to the contraction a marked character; tetanic rigidity and contouration of stiffened loops visible above the *niveau* of the abdomen.[3] In the not chronic conditions the muscles are soon exhausted and contractions give way to paresis. In the words of Schlange, the peculiarities of obstruction ileus are the absence of the initial, continuous pain, the absence of early collapse; the presence of readily recognizable distended loops with more or less strong peristaltic mobility and the presence of disturbances of any kind, which may show the existence of causal or chronic conditions in the abdomen and especially in the bowels.

DIFFERENTIAL DIAGNOSIS.

I have aimed in the foregoing to present a basis for subdivisions, into which may fit the various important anatomic conditions in a concrete form. Let me then presume that in each case a careful history, especially of previous abdominal conditions, has been elicited, urine, blood and all hernial openings been examined, that a diagnosis of ileus has been made, that congenital and dynamic ileus have been excluded and that the case is one of mechanical ileus of the strangulation variety, and in a fairly early stage. Question, is it due to band or string, volvulus, intussusception, or internal hernia? What local signs can help us? The abdomen is fairly distended, but on inspection and careful palpation we find a loop of the bowel, fixed, distended and paralyzed. The strangulation is then due to a band, diverticulum, volvulus, or invagination. The appendix vermiformis, for our purpose, is practically a diverticle, and a diverticle practically a band. Strangulation due to band is very rare in childhood, patients are generally young adults; in 68 per cent. there is a history of peritonitis and usually the small intestine involved. The onset is sudden, pain early, continuous, incarceration collapse well marked, absolute constipation, stercoraceous vomiting late, no tenesmus, no bloody mucous discharge from the rectum; rectum empty, holds large quantity of injection fluid, distension gradual and central, territory occupied by large intestine empty and collapsed; if the appendix acts as band, the fixed loop is in the right lower abdomen. Volvulus of the sigmoid colon affects most generally an adult between 40 and 60 years, is rare before 40; is four times more common in men than in women; there is a history of chronic constipation; the pain is less severe than in band, collapse less intense; the vomiting later, tenesmus is present in 15 per cent., distension begins on the left side in a loop, which gradually moves upward and to the right hypochondrium; the distended colon can be made out; on examination per rectum we may feel the end of the distended loop in the pelvis or abdomen; the rectum will not hold a quart of fluid. In torsion of small intestine around a mesenteric axis pain is more acute, distension central, large intestine empty and collapsed, will hold quarts of fluid, vomiting early, rarely stercoraceous, no history of peritonitis. Intussusception mostly in the young; 50 per cent. in children under 10 years, onset sudden, pain at first intermittent, vomiting not so early, is less urgent and sometimes absent; there is tenesmus and bloody and mucous discharge from rectum, sausage-shaped tumor generally felt in the abdomen by palpation or the intussusception found in the rectum. There remains the internal herniæ, of which the hernia duodenojejunalis is the most frequent. This is probable in strangulation ileus in the absence of a fixed, immobile, paralyzed loop, with intense thirst, early vomiting, rarely becoming fecal. Quoting again from Leichtenstern:

> I consider probable diagnosis possible under favorable circumstances and with a fairly large hernia. The circumscribed, spherical distension of the mesogastrium, collapse or sinking of the territory occupied by the colon, the palpability of a circumscribed, tense, elastic, spherical mass, which gives the impression of a large, somewhat movable cyst, which tends toward the left from the mesogastrium, the quality of a definable tumor which gives a sonorous percussion sound and on auscultation loud, clear, intestinal noises with bleeding from the rectum and hemorrhoids, from compression of the inferior mesenteric veins, seem to make a fairly clear picture.

Jannesco has collected 64 such cases. Koenig[18] states that of such herniæ, of which 50 are beyond doubt, according to a critical review by Sonnenburg, who operated on one case successfully without having recognized its nature, not one had been diagnosed. The indication was incarceration high up in the small intestine. Those in the fossæ subcecalis or intersigmoideæ are very rare indeed, and have not been found sufficiently often to offer a diagnostic hint beyond strangulation not coming under the described heads. Obstruction ileus having been diagnosed, how may we differentiate its various forms? Obturation may cause symptoms of acute or chronic obstruction; the acute generally grafted upon the chronic, except in gallstone, enteroliths and foreign bodies. Senn's[19] experiments seem to demonstrate that occlusions of the lumen by foreign bodies give rise to symptoms of obstruction after tissue changes have begun in the intestinal wall from contact with the foreign body. While the symptoms in gallstones frequently are very acute, they lack the intensity characteristic of strangulation. The presence and character of foreign bodies, we learn from the history; attacks of gall colic accompanied by severe symptoms or of jaundice more or less persistent, will indicate the probable nature of the obturation. Acute symptoms of obturation point to enteroliths, after the exclusion of foreign body or gallstone. Occasionally, under exceptionable circumstances, the stone may be felt. Acute symptoms of obstruction by invagination are soon lost in the picture of strangulation, the finding of the tumor, often sausage-shaped, the tenesmus, bloody mucous discharges with the indications from the age of the patient, help to make a correct diagnosis.

THE DIFFERENTIAL DIAGNOSIS OF CHRONIC OBTURATION ILEUS.[20]

The progressive development in the clinical knowledge of enterostenoses may be best appreciated by a study of the works of Leichtenstern, Treves and Nothnagel. In them we find demonstrated the close relation between the motor signs and the chronic development of the impediment. Treves describes graphically the colic attacks, and Nothnagel the rigidity and tetanic contractions of the bowel above the obstruction. The colic attacks are not of a duration as in kidney or gallstone. They are rather like short and periodic labor pains, accompanied or followed by loud splashing, tinkling, purring noises and subjective feeling of turning about or rolling of the intestine. I can not here go more extensively into a detailed study of the subject, but the value of a correct interpretation of the variety, duration and location of the contractions, etc., is indisputable for the differentiation between stenosis of the small and large intestines. Acute attacks of varying intensity appear from time to time. In the intervals, the symptoms of obstruction may subside. In time the intervals become shorter and the attacks longer and finally complete. In fecal impaction vomiting appears late and is never feculent until after a period of complete obstruction; constipation is pronounced, increasing; meteorism gradual; the abdomen feels full and doughy and a tumor can be made out in the colon or rectum. As a rule, it is of a doughy consistency, but may be hard and tender on pressure, in which latter peculiarity it differs from the carcinoma. The greater number of the cases of partial chronic stenoses depends on the development of strictures, malignant and cicatricial. Nothnagel says of 343 cases of carcinoma of the bowel recorded postmortem, 162 were rectal, 164 of the colon, 10 of the ileum, none of the jejunum and 10 of the duodenum. Therefore the large majority are within reach of touch, sight and palpation. Malignant strictures are more common in the large, cicatricial more common in the small intestine. Stricture of tubercular origin is most frequent in the ileocecal division and most frequent in the ileum; those following syphilis and dysentery, in the rectum and colon; cancerous strictures are rare before forty; cicatricial occur earlier in life, often preceded by a history of tuberculosis, dysentery, trauma or strangulated hernia.

Obstruction from compression by tumor or peritoneal exudate and matting together of intestine can generally be determined by a careful physical examination of the abdominal and pelvic cavities, and its character, location and probable influence on the intestine, estimated. Nothnagel says that the anatomic diagnosis of intestinal obstruction is the most difficult of anatomic diagnoses. I entirely agree with him. Nevertheless the attempts toward solving the difficulty should be persistently continued until the goal be reached. When the symptomatology of obstruction of the bowel shall emerge from its chaotic condition, the indications for prompt and correct therapeutic measures will become apparent to the physician, and surgery, stepping in early, will score some great triumphs.

REPORT ON TWO OF THE CHILDREN OPERATED ON BY LORENZ.

HARRY M. SHERMAN, A.M., M.D.
Professor of Surgery in the University of California, Surgeon to St. Luke's Hospital, and Orthopedic Surgeon to the Children's Hospital.
SAN FRANCISCO.

In May, 1903, I removed the dressings from two of the children who had been operated on for congenital dislocation of the hip by Professor Lorenz of Vienna, when he was in San Francisco in November, 1902. One of these cases I had seen in November, 1900, but the parents then declined treatment, coming back to San Francisco two years later, however, when they heard of Lorenz. This case returned to me by agreement when the time came for the removal of Lorenz's dressings. The other case was the child of a physician, and had never been seen by me until he was on the operating table, but returned to me, also by agreement, as did the first.

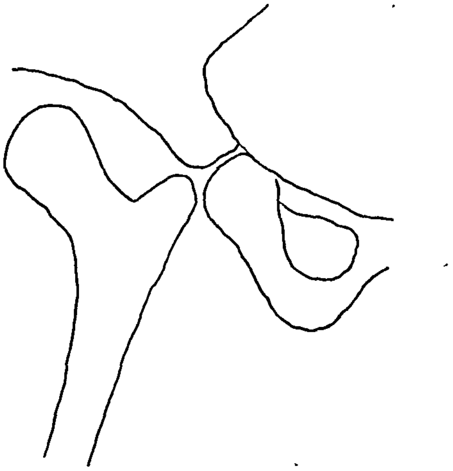

Fig. 1.—Case 1. Outline of upper end of femur and pelvis immediately after the removal of the Lorenz dressing, May 11, 1903. (Reduced from radiograph.)

In each instance there were several surgeons present when the splints were removed. The children were radiographed immediately after the splints were off, before any examination was permitted, and this record being thus secured they were examined and such notes as were necessary were made.

CASE 1.—A boy, aged 5 years. I had seen this child in November, 1900, and he had then an anterior dislocation. He had a slight limp only. By November, 1902, his condition was worse and Lorenz made an effort to put the head into the acetabulum. The plaster-of-paris dressings put on by Lorenz were worn continuously until taken off in my office. The radiograph (Fig. 1) was taken and the following description was made at my request by Dr. James T. Watkins. It expresses my own findings perfectly, and is given as the joint testimony of Dr. Watkins and myself.

"The plaster dressing applied by Professor Lorenz after he had operated on the 'Case 1' boy in November last for congenital dislocation of the left hip, having been removed, the boy was examined and *x*-rayed without removing him from the table.

"I found the left thigh flexed on the pelvis to about a right angle and abducted till it lay in the frontal plane of the body. Neither outward nor inward rotation was apparent. The leg was flexed on the thigh but could be extended. In other words, the limb was in the attitude in which it was put in the plaster dressing. There was some atrophy of the muscles of both the leg and the thigh.

---

[20] Sklodowski: Grenzgebiete der Medicine u. Chirurgie.

"The femoral artery could not be compressed between the finger and femoral head as is normally the case; but the head was recognized external to the artery and more superficially placed than usual in a position beneath the anterior superior iliac spine. The greater trochanter was in a plane posterior to that in which the head lay. It was placed at the level of the acetabulum. Whether or not it lay in the same frontal plane as the acetabulum could not be determined."

The head was in a subcutaneous position in the outer part of Scarpa's triangle, while the trochanter was somewhere behind and internal to it. The condition was not one favorable to any stable support of the pelvis on the femur, and I suggested to the mother the propriety of a cutting operation to try to improve things. This was agreed to, and the child was sent back to the hospital.

The following account is made from notes dictated during the operation:

As the child had been using the limb for about a week I found much greater mobility at the hip than had existed when the splint was first removed, but the position of the head was that noted by Dr. Watkins. As I adducted the limb, under anesthesia, there was outward rotation and the trochanter assumed a position inward and posterior to the head. Inward rotation, to which there was some resistance, put the head in the position ordinarily occupied by it in anterior dislocations, but the position was not maintained and the head moved outward when the limb was left unheld.

A longitudinal incision was made, internal to the tensor vaginæ femoris and directly down to the head. This was just beneath the fascia lata. Around the head was a thin fibrous layer which I at first took to be the joint capsule, but which I later found to be only a layer of laminated fibrous tissue, an adventitious capsule. This was freely laid open and long catgut loops put in the sides of the incision to act as retractors. The cartilage of the femoral head, now exposed, was found to be eroded, as if by some absorptive process. The pit for the ligamentum teres was obvious, but there was no ligament.

Usually at this stage of the operation for reduction by arthrotomy I am able, by flexing the hip to a right angle, to thrust my finger down to, and sometimes through, the constricted part of the capsule, but in this case it was impossible. There was no such open path. Further dissection showed a band of capsule, coming from the lower part of the acetabulum and twisted around behind and above the neck; but partial section of this did not open up the way to the acetabulum. Finally the rim of the acetabulum was located and the capsule opened there. It was then found that the manipulations in November, 1902, had torn the capsule, had thrust the head through the opening and left it among the muscles at the outer part of Scarpa's triangle and just beneath the fascia lata, while the trochanter had been crowded into a position internal and posterior to the head and very nearly into the acetabulum.

The acetabulum, once exposed, was found to be very shallow, but the head was easily put into it, or on it, by an inward rotation movement. Very little capsule, however, was left in front of the head, and this was a serious loss.

The wound was closed in the usual way and the limb and pelvis put in a plaster-of-paris spica, the thigh being flexed, abducted and rotated in so that the pull of all the long muscles of the thigh should crowd it directly against the floor of the acetabulum.

The disclosures of this incision suggest certain thoughts. It is obvious that in all cases in which an anatomic reduction can not be made the body weight must be carried by the capsule of the hip joint. It seems equally obvious that an intact capsule would carry that weight better than one that had been lacerated, and so it is impossible to avoid the conclusion that any manipulation that lacerates and weakens the capsule is a detriment. Now the tendency is for the dislocation ultimately to become a posterior one, even though it is anterior in infancy and childhood. I can see no condition, exposed by this incision, which could be counted on to prevent this backward movement. If the movement took place one would expect the head, entangled in the rent in the capsule, not to move as fast as the trochanter, and an outward rotation of the limb to occur. Furthermore, the rent in the capsule must be on the distal side of the constriction, and the moment it is made, all hope of crowding the head through the constriction and into the acetabulum is lost; moreover, if the head be now put on the acetabulum it is wasted effort, for the proximal part of the capsule is stretched over the acetabular cavity from rim to rim, and not only closes it, but makes the cavity, perhaps originally not deep, still more shallow. There is not room in a normal hip joint for a layer of capsule between the head and acetabulum; there is still less with the parts deformed as they are in congenital dislocation. Just how this boy was benefited by the manipulations of Professor Lorenz, I can not myself see. Of course, it may be said that I robbed him of the possible benefit by doing a cutting, "bloody" operation. For this reason Case 2 has not been operated on and can now be studied.

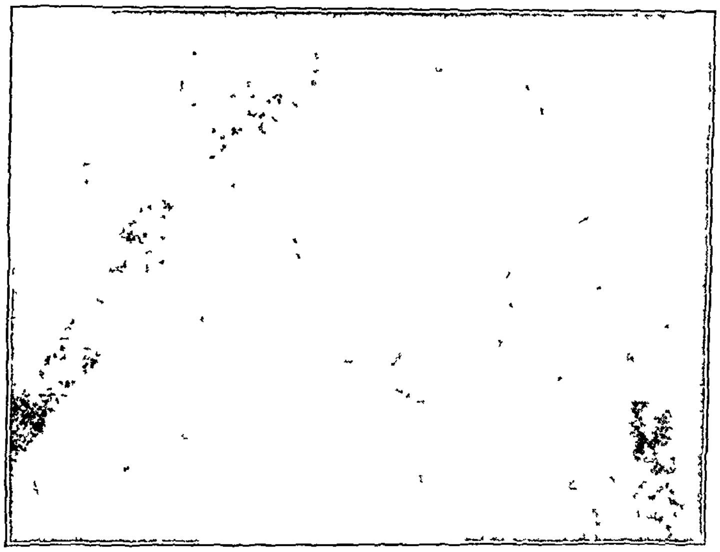

Fig 2.—Case 2 Immediately after removal of the Lorenz dressing, June 3, 1903.

Case 2.—Boy, 4 years old, with a posterior dislocation of the femur. He was operated on at the same time as was Case 1, by Professor Lorenz at the Children's Hospital. The splint was taken off in my office, June 3, 1903, having been on a little over six months. The same method was followed as in Case 1, and the child was radiographed immediately after being taken from the splint. Palpation showed the femoral head to be in the outer part of Scarpa's triangle and very near to the skin. There was a little active motion, and more passive motion. The child had walked in his splint, but could not do so after the splint's removal. The conditions, on examination, were so similar to those in Case 1 that I presume the same amount of mischief was done, that the capsule had been torn and the head thrust through the rent out into the surrounding muscles, that around it had developed an adventitious thin capsule, and that the untorn portion of the capsule reached up behind the head to the upper part of the neck near the trochanter, while the acetabulum was still closed by the capsule stretched across it, from rim to rim.

Examination of Case 2, October 10, four months after the removal of the splint, and during which time the leg had been in use, shows that the child stands without lordosis; he walks with a little straddle of the legs, and with a turning out of the foot; at the same time there is a lateral and backward sway of the trunk on the pelvis, lordosing and bending sideways the lumbar spine in each step. The limp was observed by Dr. Watkins and myself, with the child nude and walking to and fro in a good light. It is certainly a definite quantity. The femoral head can be felt to be just outside of the anterior superior iliac spine and above the acetabulum. The trochanter is behind and internal to the head. The neck is, consequently, directed forward and outward and upward, the latter in accordance with its natural obliquity to the shaft. About 1 cm. or 1.5 cm. up-and-down motion is permitted by the head with the limb extended, and when the hip is flexed, the center of motion is at the trochanter and the head travels upward and backward with the flexion. The center of motion is presumably at the point where the probable rent in the capsule embraces the femoral neck, perhaps close to the trochanter, though it seems to be in the trochanter itself. In its present place the head is further from the mesial anteroposterior plane of the body than it would be in either of the ordinary anterior or posterior positions, and this will explain the most obvious lateral sway in the step, for the child has to make this motion in order to balance the body over the unstable and eccentric support. The limb is 2.5 cm. shorter than its mate. The parents say they can see no improvement in the walk since the operation. A radiograph (Fig. 2) was taken at this time. It shows shadows which correspond with the clinical findings as described above.

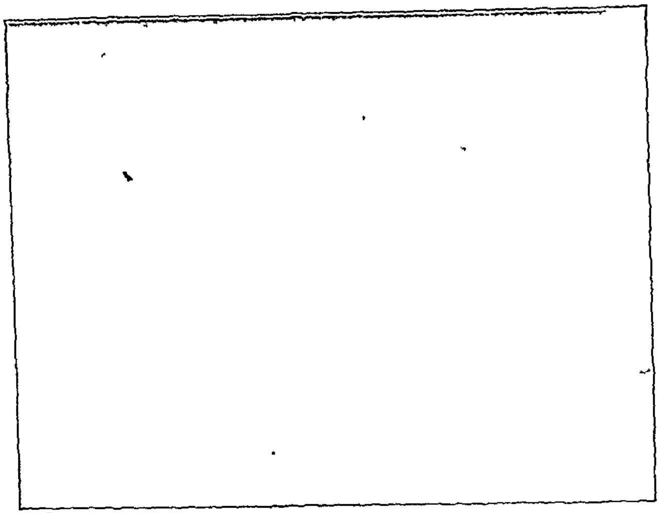

Fig. 3.—Case 2. Showing upper end of femur and the pelvis, the toes held to point forward.

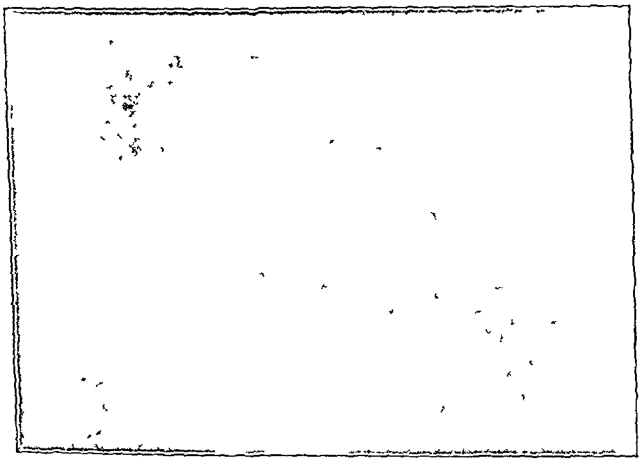

Fig. 4.—Case 2. Showing upper end of femur and pelvis, the leg being permitted to roll outward.

Assuming that the capsule was ruptured in this case, as it surely was in Case 1, and admitting, for it can not be denied, that the body weight has to be carried by the capsule, the shortening of the limb now must be greater than it was before the manipulation; for the capsule now reaches only to the neck, whereas before it reached to the head. I can not state that the limb is shorter, for I never examined the boy before his operation, but I believe it is so. Now, in this position, with the head looking forward and the trochanter backward, the toes point forward and outward. The trochanter is apparently behind and the femoral head just above the acetabulum. If the upper end of the femur travels back to the position on the dorsum, the outward rotation may be increased, with an increase in the awkward position of the foot. This will be of no benefit to the child if it takes place. If it does not take place, the present position and the present eccentric point of support and the semi-waddle it imposes, will last through life. I can not see that this is any improvement on the conditions existing before the operation.

The radiographs show, in Figure 2, the position of the parts when the original splint (Lorenz's) was taken off; in Figure 3 the position which the upper end of the femur takes in relation to the pelvis when the foot is held so that the toes point forward, and in Figure 4 the same when the limb falls into the spontaneous outward rotation position.

TABLE WINES. ARE THEIR USES TO BE ENCOURAGED?*

HENRY O. MARCY, A.M., M.D., LL.D.
BOSTON.

I suppose the preacher of even a lay sermon is expected to select some text more or less befitting the subject of his discourse; therefore, I have chosen I Timothy v, 23, "Drink no longer water, but use a little wine for thy stomach's sake and thine often infirmities."

In these days of biblical exogesis the reverential respect of the fathers has become badly shaken, and with perfect complacency we now revise the revision of the revised word until, like the boy's jackknife, the new handle, fitted to the new blade, is still claimed to be the same old knife.

The first revision was in the earlier day, when the crusaders of the new temperance faith openly absolved allegiance to King Alcohol, and declared that public tippling at the house of the tapster should be abolished. The temperance lecturers dwelt on the evils and the doom of these open enlisted followers of the King, and the pictures of the physical, financial and moral ruin of these men was so graphically depicted that every listener would have had a delirium of nightmare had he not conscientiously believed that the photographic vision was of the "other fellow" and not of himself. These same moral temperance teachers, for the most part, accepted it as orthodox that whisky, brandy, rum, gin, etc., were excellent medicines, and that when the tides of life ran low they were indispensable to tone and brace up the general system.

After having shown that the rôle of these so-called remedial agents was founded in a misconception of a conservative prejudice descended from the fathers, it was asserted, and abundantly proven, that strong alcoholic drinks were injurious as medicines, and rarely if ever to be administered for the good of the patient. Still further revision showed that when these stimulants were taken, even in small doses, but in daily repetition, certain chronic changes of the tissues ensued; that such individuals, although seemingly well, often added unduly to their weight by the lack of elimination of waste material, and that they became subject to certain chronic diseases affecting especially the kidney and liver.

---

* Read at the annual meeting of the American Medical Temperance Association at New Orleans, May, 1903.

Then it was demonstrated that the resistant power of the organism to disease was lessened. As an illustration, an increased tendency to tuberculosis.

A still more careful analysis of these revisors demonstrated that the experience of the centuries was all wrong; that the witness, who, in January most earnestly testified that he drank alcohol and it warmed him, was considered prejudiced, especially when it was shown in evidence that the same individual claimed that after taking his favorite beverage in July he was cooled thereby.

The physiologist who became a member of this investigating committee, after a prolonged and profound research, showed that the especial monitors—God's sentinels at the inner gate of our consciousness—had been more or less narcotized, and, therefore, did not correctly report the state of the weather. Following this new lead of investigation, it was demonstrated that in perfectly healthy young individuals, selected for the test, moderate doses of alcohol lessened the special senses in an almost uniform ratio, so that vision, hearing, smell, taste, touch, muscular force were all appreciably lessened; therefore, it followed that the endurance and fighting qualities of the soldier and sailor are impaired; that the soldier can not march so far, endure hardship as well or shoot as accurately, and that since each soldier of the United States represents an average annual cost to the government of $1,000, therefore the economics of the equation demanded that as a fighting machine his ability should not be impaired by the taking of alcohol.

The revisors of the revision were even now not satisfied, and by further scientific investigation attempted to prove that alcohol in all its different forms of drink is alcohol still, and that it does not matter whether it represents a weak solution, as ale, beer, cider or light wines. In other words, that an ounce of alcohol taken in a quart of beer or in a pint of light wine is just as injurious as if diluted in the same amount of water; that it is a poison, and exerts its influence on the tissues in a directly relative manner.

Now if this is the modern, scientific explanation of the effect of alcohol on the animal tissues, where will we find the truth of our text as announced by the great Apostles? And why should we not accept the teachings of our fathers, fortified by the experiences of the centuries that the discomforts due to a defective digestive process might be speedily relieved by a dose of hot toddy. Our physiologist says the sensation of discomfort is relieved as by a narcotic, but the digestive process is retarded rather than enhanced by the remedy.

Some scientists stoutly affirm that a small quantity of alcohol may be safely oxidized in the tissues, and have even gone so far as to state that the average healthy adult may thus dispose of two ounces of alcohol in twenty-four hours, transposing it by a process of oxidation into heat units. But the same opinion is carefully qualified by the statement that the temperature of the individual may be more easily and safely maintained by the transposition of ordinary food products.

If this brief résumé of the physiologic effect is correct (and in the support of this opinion it is easy to quote a long array of the best modern scientists), what can be said in favor of the uses of wine as table beverages?

Even from the remotest antiquity, in every generation and among all peoples, the vine has been cultivated and its products held in the highest esteem. Poets have vied with one another in singing its praises, and the grape in its many varieties has justly held a high place in public favor. Inasmuch as it was impossible to supply this fruit in perfection in general use, except for a brief period of the year, it was perfectly natural that some measures should be devised for better preservation, and it was easy to determine that this was not possible, except through the processes of fermentation, which modified their juices, and by the addition of a considerable amount of alcohol under favorable conditions rendered permanent their keeping qualities.

Very modern science has taught the causes which produce in great variety the flavor or bouquet, which renders wines so desirable and causes them to be held in high esteem. The general public has been taught for the most part only the injurious rôle of the bacterium, so that, indeed, it is often stigmatized as deadly. The fine flavors of the high-priced creamery butter are now very commonly produced by the introduction into the cream of a special variety of bacteria cultivated for the purpose. Cheese owes its flavor to certain forms of these organisms, and of more recent demonstration is the proof that in the fermentative process of wine-making certain bacteria may be introduced which produce the much-desired flavors of the high-cost vintage which was supposed hitherto possible to obtain only in certain especially favored cellars.

The wise custodians of these establishments had for many years religiously believed, not alone in the even temperature and dryness of their cellars, but had insisted on the advantage of letting them from year to year remain absolutely uncleaned. In this way certain ferments were readily preserved indefinitely, and were thus accidentally introduced into the ripening wine. Profiting by this, selected varieties of bacteria are now cultivated with the assurance of an annual product of high-grade wines. Thus it is demonstrated that it is not the percentage of alcohol which causes these wines to be so high-priced and much sought after, but something else. And we may well ask ourselves if modern science may not give us this something else in even more desirable form and eliminate the alcohol.

We are all singularly creatures of habit, and become so wedded to certain tastes and flavors that the deprivation of the same is held by the individual as a more or less positive detriment; and this brings us to a subdivision of our subject, to which I can only allude, the so-called flavors, condiments, relishes, etc. The physiologist will tell you that there is a reason why every man requires salt in his daily food, but he will be troubled to explain the almost equally universal demand of the Mexican for the extraordinary use of pepper and of the Italian for garlic.

It would be hardihood on the part of any scientist to advocate the adoption of the universal ration, although he can demonstrate most definitely that a healthy individual of a fixed weight requires certain given amounts of starch, fats and proteids. When we add to these fundamental elements of nutrition the thousand and one various modifications of food, we recognize that we are doing it chiefly for the purpose of making our daily diet more attractive and giving a better relish for food.

The modern miracle of the preservation and transportation of food stuffs renders it possible to place on our tables in excellent condition the products of all climates at reasonable cost. The banana, a generation ago a rare and expensive tropical fruit, has become of almost daily use, even in homes of those in limited circumstances. Preservation by use of cold storage has worked a wondrous change in the continuous supply of fruits. At a slight increase of expense apples in good condition are abundant in the market for the larger portion of the year. This is also true of oranges and lemons, etc. The strawberry, from its first fruiting in Florida until the end of the season in Nova Scotia, furnishes an abundance of delicious fruit at moderate cost. These are selected as illustrations of the wonderful modern progress which permits the table of those even of limited income to be supplied with healthful accessories to diet which serve as relishes to the appetite rather than absolute necessities for the preservation of existence.

That which is true of fruits is also true of modern beverages, which in a still greater degree are classed as relishes or aids to appetites. Pleasant, refreshing drinks in daily use are made from these fruits, as lemonade, fruit sherbets, etc. Scientific processes are yet to greatly lessen the cost of fruit juices and proportionately wisely increase their use. Modern processes render it perfectly feasible to concentrate the juice of a lemon into a quarter of an ounce of fluid and render its preservation indefinite, thereby reducing the cost to the consumer with equal profit to the grower by three-quarters. That which is true of the lemon is true of many other fruits, especially that of the grape. The large expense of light wines lies in the hitherto necessary bottling and handling of its large factor in bulk, which is only water. By the careful abstraction of water, claret is easily reduced in bulk by three quarters. These condensed wines keep much better and are ready for use by the simple addition of water. This process is already in use in France and has been enthusiastically recommended. The abstraction of the water without damage to the wine, by any of the heat processes, has proven to be impossible since the delicate aroma which is the chief attraction of the wine is thrown off even more rapidly than its alcoholic contents. Although every housewife delights in the preservation of fruits which add so materially to her table delicacies, she is painfully aware that despite her utmost care, a large part of the delicate aroma of the fruit is lost in the heat processes necessary to the preserving.

Somewhat recently advantage has been taken of the fact that the water in fluids submitted to low temperature under favorable conditions became ice crystals, entirely free from admixtures which the fluid contained. Therefore, wines submitted to this process parted with a large share of their bulk without loss of their alcoholic or other essential qualities. Fruit juices submitted to the same process are easily concentrated in the most remarkable degree, and there is every reason to believe that in this way very many additions can be made to our table delicacies. Most delicious beverages which many think are preferable to our most costly wines can be manufactured in this way, preserving without detriment the exquisite flavors and colors of the carefully ripened fruit. That such beverages are beneficial, no one can question, and they may be destined, in a degree at least, to supplant our enormously excessive use of tea, coffee and alcoholic stimulants.

A brief description of the process may be instructive. The fluid to be concentrated is subjected to a temperature below freezing, and the ice crystals as formed are mechanically broken up. The resulting product may be considered an unsweetened fruit sherbet. This is transposed into a centrifugal machine of high power, and the ice crystals are driven out so forcefully that they resemble snow ice, and require breaking up with a hammer. The uncongealed concentrate diminished 60 to 80 per cent. of its original bulk. is ready for preservation. Such a process is not an expensive one and can easily be installed at places convenient of access at the cost of a few hundred dollars.

The quality of the product will necessarily depend on the quality of the fruit used, as defective flavors are as much intensified by concentration as desirable ones. My attention was first called to this process many years ago, in its application by the farmer to late-made cider. He purposely exposed his cider in casks to low temperatures, freezing it as much as possible, then draining off a concentrate reduced to a fifth or even a tenth of the former bulk. The processes as above outlined have passed the experimental stage, so far as the economy of production and quality of product are concerned. Applied to milk, 60 per cent. of its water is easily extracted by a single freezing, its keeping qualities greatly enhanced, so that the family supply of milk can be purchased weekly instead of daily, with immense saving of cost alike to the producer and consumer.

It is not too much to believe that revolution in the drinking habit may be expected with an almost limitless profit to the consumer. In the place of table wines, as now used by the comparative few and now believed to be demonstrated of positive injury when habitually taken, there will be furnished to the many the fresh juices of the grape and other fruits, which, constantly used from youth to old age, will be found healthful and invigorating.

When a man may be better clothed, better housed and better fed, he is no longer satisfied with his former estate. When he may drink freely without being intoxicated, when he may have more delicious drinks which appeal to his appetite without detriment to his physical and moral well being, he will as readily make choice of his new beverages.

Another step in the progress of civilization has been made, and a new era is opened up to him. Modern science is the magic transformer of the centuries.

Reorganization of Medical Societies.—The project which involves a merger of the county and state medical societies with the national organizations has much in it to commend. Under the new régime, the county society is made the unit and enjoys representation at the state association, which in turn sends delegates to the parent organization. Both of the latter, moreover, are, for convenience sake, divided into legislative and scientific sections which conduct the business pertaining only to their respective departments. All prospective members, therefore, are required to join first their county or district society—which action renders them eligible for membership in either of the others. The advantages accruing from an amalgamation of all or most medical associations of the United States is apparent to all and the last obstacle in the way of such advance was removed by the national body when the "code of ethics" was abolished and gave place to the "principles of ethics" which are merely advisory and suggestive and place no undue restrictions.—*New England Medical Monthly.*

THE DECAPSULATION OF THE KIDNEY,

WITH REFERENCE TO THE CONCOMITANT INTRA-OCULAR COMPLICATIONS IN THE CHRONIC FORMS NEPHRITIS.*

GEORGE F. SUKER, M.D.

Professor of Ophthalmology in the Post-Graduate Medical School; Clinical Instructor in Ophthalmology in the Medical Department of the University of Illinois.

CHICAGO.

The object of this paper is to elicit the interest of the members of this Section in determining whether or not the decapsulation of the kidney can be accepted as a curative or as a palliative measure for the various intraocular complications accompanying either the diffuse, interstitial or chronic parenchymatous nephritis. The question of decapsulating the kidney[1] still attracts considerable attention,[2] not only from the standpoint of the surgeon but from that of the internist as well. The writer is well aware of the fact that it is rather early to make any definite statements or draw any definite conclusions as to the merits or demerits of the operation from an ophthalmologic point of view.[3] But, if the paper should arouse enough interest in the matter so that before long we might have either a symposium or a more extended report on this subject, as is our wont in such matters, we would be in a position to decide a very important question which would be infinite in its reachings. In this particular, it is only necessary to call attention to the tremendous death rate in those forms of subacute or chronic nephritis associated with deep-seated fundus lesions, especially albuminuric retinitis.

The surgery on encapsulated organs, such as the kidney, liver and spleen, is of recent origin. The pioneers in this field are Reginald Harrison of England, Israel of Berlin, Pean and Pousson of France, Ferguson of Chicago, and Edebohls of New York. It is to be hoped, however, that with reference to the decapsulation of the kidney it will not be as it was with the splitting of the capsule of Glisson, namely, a nice experimental operation but of no practical value, as its results are not definite.

It was Edebohls[4] of New York who first split the renal capsule with the avowed intention of curing a case of chronic interstitial nephritis. Since then, a number of surgeons have performed the operation. However, no mention at all was made in most instances of the condition of the eye at the time of the operation, nor, for that matter, at a subsequent time. It is sad, but nevertheless true, that the general surgeon pays very little attention to the eye when it comes to operations on the kidney. This was a pertinent point brought out by an extensive correspondence on this very subject in order to gather data for this paper.[2]

The very fact that we, as ophthalmologists, are often the first to apprise the patient of any kidney lesion makes the subject of great interest to us. And, if the future will soundly establish the value of kidney decapsulation, it is our duty to follow up such cases now, with or without eye lesions, as submit to the operation.

True it is that we do not at present definitely know how the operation accomplishes the good it does,[5] even in those cases without deep-seated fundus lesions. That is to say, the pathologists have been unable to give any definite data, and experimental work[6] along this line does not seem to offer a very satisfactory solution.

The deep-seated fundus lesions usually accompanying an interstitial, parenchymatous, or diffuse nephritis of the chronic variety, are about the same in character. We know these to be a simple retinitis, neuroretinitis, optic neuritis (all with or without retinal hemorrhages), and some form of choroiditis. From the fundus alone we can not determine what form of kidney lesion is present. But when a retinal lesion is present we know that it materially adds to the gravity of the prognosis. The severity or extent of the fundus lesion in a measure indicates the amount of kidney and vascular involvement. The reverse of this statement is also a fact, in a limited degree.

The frequency with which the fundus is implicated in the various forms of chronic nephritis is startling. According to Lécorche 20 per cent., according to Galezowski 33 per cent., and according to the writer at least 30 per cent. of all chronic Bright's disease patients present some fundus complication. It is not by any means such a very doubtful statement that every one with a chronic nephritis will probably have some fundus implication before he dies (provided the nephritis carries him off). For we know that the fundus may be involved and yet the patient not be aware of it. There is no stated time during the nephritis for the retinal or other fundus lesion to appear. At times these lesions are the initial symptoms; again, they appear very late or very early in the attack of nephritis. And we are aware that frequently the very first diagnosis is made by an ophthalmoscopic examination. So much importance ought we to attach to this statement that a careful examination of the kidney should be made whenever a retinal lesion of an inflammatory nature is detected. This is also true with reference to the acute forms of nephritis on behalf of the retina.

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. J. A. Lippincott, Frank Allport and John E. Weeks.

[1] Following is the main surgical literature on decapsulation of the kidneys. There are included references to two articles (by Ferguson and Whitacre), which have appeared in THE JOURNAL since the reading of the paper. Edebohls, G. M.: "Renal Decapsulation for Chronic Bright's Disease," N. Y. Med. Record, March 28; 1903; also "Question of Priority in the Surgical Treatment of Chronic Bright's Disease," N. Y. Med. Record, April 26, 1902, p. 651; also, "The Cure of Chronic Bright's Disease by Operation," N. Y. Med. Record, Dec. 21, 1901, p. 961; see also Brit. Med. Jour., Nov. 8, 1902, p. 1507. Ferguson: THE JOURNAL A. M. A., July 4, 1903. Whitacre: THE JOURNAL A. M. A., May 23, 1903. Primrose, A.: "The Operative Treatment of Chronic Bright's Disease," Canadian Jour. of Med. and Surg., 1902, xi, p. 143. Harrison, R.: London Lancet, Jan. 4, 1896, p. 18; also British Med. Jour., Oct. 19, 1901, ii, p. 1125. Rovsing, T.: "Operative Treatment of Chronic Nephritis," Mittheilungen a. d. Grenzgebieten d. Med. u. Chirur., 1902, vol. x, p. 288. Guiteras, R.: "The Surgical Treatment of Bright's Disease," N. Y. Med. Jour., 1902, lxxv, p. 847. Lyman, C. B.: "The Surgical Treatment of Chronic Bright's Disease," THE JOURNAL A. M. A., 1902, xxxviii, p. 1030. Pousson, A.: "De l'Intervention Chirurgicale dans les Nephrites Médicales," Annales d. Maladies d. Organs Genitourinaires, 1902, xx, pp. 513, 641 and 832. Israel: Deutsche med. Woch., Feb. 2, 1902. Gradle, H.: "Neuroretinitis Due to Disease of the Kidney," Chicago Med. Recorder, Nov. 15, 1902, p. 321.

[2] About 200 letters were sent out by the writer to men of repute, both surgeons and ophthalmologists, in various sections of the country in reference to this question.

[3] This is, perhaps, the first attempt that ever has been made to gather data and discuss this question from the standpoint of the ocular involvement in chronic nephritis and its relation to decapsulation.

[4] This was on Jan. 10, 1898. The first operation and the five preceding it which led up to the question of decapsulation are reported in the Medical News, April 22, 1899.

[5] Harrison attributes the results to the relief of tension. Edebohls and others add to the relief of tension the establishment of a more extended vascular formation with a greater anastomosis. Ries, Bernays and others do not place any weight on the new vascular formation. Zeit of Chicago says the kidney regenerates function quite rapidly if tension is removed. Ries made sections of two kidneys and found no increased blood supply. Israel says concerning the mechanism of the operation that an inflamed tissue may be made to retrogress toward the point of health by splitting the affected structures. According to him, new venous anastomoses are formed between kidney and capsule.

In the eye, the operation causes a decrease in the amount of albumin in the lymph channels, thus reducing the liability of deep ocular complications in consequence of lymph and vascular disturbances. This idea is advanced by Oliver and is, in a measure, supported by the writer.

Perchance the free circulating albumin takes on a certain toxic tendency and in this way excites inflammatory reactions in the retina or other eye structures.

[6] Albarran and Bernard found in rabbits a rapid regeneration after the splitting of the capsule. Within two weeks it was reformed and within two months as dense as the normal capsule and not as vascular. The cortex showed superficial lesions, not very extensive. See also La Semaine Médicale, 1902, vol. xxii, p. 215.

Tait of San Francisco, on everting the kidney from the capsule in numerous rabbits, found a dense adherent fibrous mass surrounding the kidney within two months afterward. Johnson, before the California Academy of Medicine and Surgery, in November, 1902, reported a series of experiments in corroboration of the work of Albarran and Bernard.

The death rate for nephritis with fundus complications, especially retinitis, is exceedingly high. The majority of statistics of this kind were taken without reference to the fact whether the kidney lesion was unilateral or bilateral.[7] That we can have a one-sided chronic parenchymatous, interstitial or diffuse nephritis for quite a period of time is to-day a well-recognized and accepted clinical fact. We also know that a small portion of healthy kidney can meet the demands of the economy, and that two kidneys are not necessary to maintain life. Clinicians now tell us that a part or the whole of one kidney may be involved in the aforementioned diseases. True, if one kidney is affected the other is liable to become involved, as the same etiologic factor is present. Often one kidney is rather extensively involved before the other is implicated. However, should only one kidney remain involved, the prognosis as regards life is very favorable, other things being equal. These cases, however, are very rare.

The age of the patient is an important factor as regards the prognosis. Whether a unilateral or bilateral nephritis, the death rate rapidly increases in an inverse proportion to the age, i. e., in the twenties and thirties the death rate is considerably higher than in the sixties or seventies. Again, the mortality is greater in hospital than in private practice.[8]

The fundus complication, too, may be unilateral or bilateral.[9] However, the great majority are bilateral, just as perhaps the kidney lesions are more often bilateral. The fundus lesion serves as an indicator as to the extent of kidney involvement; it also serves the same as regards the prognosis. In this particular it matters little whether the fundus lesion is unilateral or bilateral, though, naturally, the bilateral involvement is the graver. Hence it may be that those with retinal complications who outlive the classical two-year period have had but one kidney involved at the time, or one may have been considerably less involved. Nevertheless, postmortem examinations show ultimately an usual bilateral nephritis and retinitis. The nephritis may exist for some time before albumin is observed in the urine, and in these cases the retinitis is often the first observable diagnostic lesion.[10] The retinal lesion may also be late in appearing, and then, as a rule, the disease makes rapid strides.

It is yet an open question in what manner the fundus and kidney lesions are associated. Traube says it depends on excessively increased arterial tension, yet in many cases there is no cardiac hypertrophy. Weeks and Samelsohn attribute it to a general vascular—both arterial and venous—disturbance which takes place in both organs at the same time. Cardiac hypertrophy[11] is an important factor in the production of the retinal hemorrhages. The theory of auto-intoxication is not to be lightly considered in this particular. Furthermore, we may have a chronic Bright's disease without retinal complications for some time, on top of which an acute attack supervenes with rapid retinal involvement.

We are now in a position to review the results of decapsulation of the kidney in this class of cases. The forecasted conclusions to be drawn from these cases are, to say the least, not encouraging. And, what is more, the cases strikingly illustrate that as yet we have found no cure or even a wholesome palliative measure for any form of chronic Bright's disease with retinal complications.

There are 15 cases, and all except two died in consequence of the nephritis within the two-year period. One of them died from tubercular peritonitis. Of the two still living, the history of one case (No. 14) is very questionable. The other is losing ground.[12] Between the ages of 20 and 40 there were six cases; between 50 and 60 five cases; between 60 and 70 two cases. The age was not given in two. These cases were nearly all in hospital practice and gave a higher death rate than the well-known Belt and Bull[13] statistics (85 per cent. for the first year and 93 per cent. of the remainder for the second year).

It is not necessary to give the detailed history of any of the cases, as they are all about the same as in everyone's practice. In Gradle's case (operated on by Ries) the improvement in the vision was simply remarkable, from 5/200 to 20/90. In the writer's case (seen in consultation with Ries and operated on by him) the vision rose from 20/60 to 20/20 minus and remained so until death. The same in this particular is true of Gradle's case. In Ochsner's case the vision was improved after the first operation. In these 3 cases, which the writer had the privilege of examining, the retinal condition improved remarkably after the operation. In one case (No. 6) before operation, the neuritis was so marked that the disc could scarcely be outlined, while after the operation it was plainly outlined. In the cases operated on by Ries and Ochsner there were no degenerative changes present in the retina. Whether this was so in the other cases could not be ascertained. However, slight degenerative changes did develop after the operation in Cases 6 and 7, as is usual in well-marked cases of this kind. The increase in the field of vision in Case 6 is not very marked, yet it shows a decided improvement (see Fig. 1).

---

[7] In order to determine whether one or both kidneys are affected, a urethral catheter or a Harris' segregator must be employed. These methods of examination have been in vogue but a short time. No statistics of albuminuric fundus complications, as regards the mortality rate, have been compiled since. Radiography may, in some instances, determine which kidney is involved, but this method is not very reliable.

[8] Bull, C. S. (Trans. Amer. Ophthal. Soc., 1886), cites a series of 103 cases, 87 per cent. dying within two years; 6 died in the third year, 4 died in the fourth year and one in the sixth year.

Miles, Miley ("The Prognosis of Neuroretinitis in Bright's Disease," Ophth. Soc. U. K., 1888), in a series of 51 cases in which the retinal lesion was determined early, 53 per cent. died within six months.

Haehnle, E.: ("Ueber die Lebensdauer der an Retinitis Albuminurica Erkrankten," Diss. Tuebingen, 1897), found that in a series of 98 cases 56 per cent. died the first year and 68 per cent in the two years. For further statistics see the following: Possanner: "Ueber d. Lebensdauer n. d. Auftreten v. Retinitis Albuminurica," Deutschmann's Beitrage z. Augenheilk., xv, s. 22, 1894.

[9] Cases where one fundus only was implicated for a long time are cited by: Leber: Handb. d. ges. Augenheilk. (Graefe-Saemisch), 1 Aufl., s. 583. Eales, H.: Brit. Med. Jour., 1884, vol. ii, p. 1248. Bull, C. S.: Loc. cit. Weeks, J.: Arch. f. Augenheilk., xxi, p. 54 (Pathology of Ret. Albuminurica). Webster, D.: N. Y. Policlinic, 1894, iii, p. 161. Werhli: Arch. f. Augenheilk., xxxvii, p. 173, 1898. Moore, O.: N. Y. Med. Jour., April 17, 1886.

[10] Hirschberg, Abadie, Gand and Eyre speak of a retinitis before albumin appears in the urine as "prealbuminuric retinitis." (Quoted by Groenouw and Uhthoff in Graefe-Saemisch Handb. d. ges. Augenheilk., 2d Ed., vol. xi, chap. xxii, p. 96.

[11] Bull, C. S., found, in a series of 18 cases, 12 with cardiac hypertrophy which had retinal hemorrhages (Amer. Jour. Med. Sc., 1873, p. 37). Litten has made the same observations as Bull. The writer has about the same experience.

[12] Reported to have died in June, 1903.

[13] The combined number of cases in the Belt and Bull statistics is 258. Of these 153 died within the first year, 88 within the second year, leaving only 17 cases to live longer.

STATISTICS OF CASES OF DECAPSULATION OF THE KIDNEYS.

Number.	Age, Sex.	Date of Diagnosis.	Kidney Lesion, Single or Bilateral.	Fundus Lesions.	Date of Last Operation.	Vascular Condition and Heart.	Immediate Result.	Final Result.	REMARKS.	Surgeons.
1	M., 67	June, 1901	Bilateral interstitial.	Retinitis albuminurica.	6, 14, '02.. .	Mitral regurg., arteriosclerosis.	Died 48 hours later.	Fatal	Cause of death, uremia. Edebohls' case No. 39.	Edebohls
2	M., 62	Jan., 1902	As above . .	Ibidem.. . . .	5, 26, '02.. .	Aortic murmur and mod'rate hyper.	Died within 12 hours.	Fatal	Acute dilatation of heart the cause of death. Case No. 34.	"
3	M., 56	May, 1901	As above . .	Neuroretinitis	5, 26, '02 . .	Cardiac hyper. and arteriosclerosis.	Improvement..	Died on Nov. 6, '02; lived 5½ months.	Both the eyes and kidneys were *markedly* improved; relapse set in. Case No. 35.	"
4	M., 21	Dec., 1900	Bilateral diffuse.	Retinitis albu. V=1/200 in each eye.	4, 16, '02.. .	Cardiac hyper. and aortic stenosis.	Vision marked improvement, kidney also.	Died 1, 18, '03	Improved for 5 mos. especially, lived 9 mos. after operation. Case No. 27.	"
5	M., 50	Apr., 1901	Bilateral interstitial.	Optic neuritis, temporary blindness.	5, 26, '02.. .	Heart on verge of dilatation, hyper. also.	Died within 12 hours.	Fatal	Very desperate case—paresis.(?) Case No. 36.	"
6	F., 22	Mar., 1901	As above . .	Neuroretinitis, hemorrhages. V=20/60.—	3, 30, '02.. .	Hypertrophy, cardiac.	Both organs improved and rem'ned imp.	Died 8, 10, '03, tub. perito's, lived about 5 months.	Albumin disappeared entirely for a time, vision rose to normal, field enlarged, kidneys operated on at two sittings; albumin returned later on.	Ries & Suker, Chicago.
7	M., 36	Aug., 1902	As above . .	Neuroretinitis and hemor. V=5/200.	9, 1, '02 . .	Cardiac hypertrophy.	Marked improvement in eyes and kidney. V=20/90.	Died Dec., '02, lived about 4 months.	Cause of death uremia.(?) Dr. Gradle said field enlarged remarkably, so did the acuity. Segregator used in Nos. 6 and 7.	Ries and Gradle, Chicago.
8	F., 30	Apr., 1900	Bilateral interstitial.	Neuroretinitis more marked in one.	Oct., 1902 .	Hypertrophic heart.	Eyes did not change, rather grew worse.	Died Jan., '03..	In this case a choked disc developed after first oper., vision decreased markedly.	O. Dodd and Ochsner Chicago.
9	(?)	Prior to 4, 10, '02	Bilateral interstitial.	Neuroretinitis	About 4, 10, '02.	Not given.. . .	Improvement..	Still living, 4, 22, '03.	General condition improved, recurrent hemorrhage into retina and more mosaics.	C. A. Oliver, Philadelphia
10	M., 50	Prior to Apr., 1902	Bilateral interstitial.	Albuminuric retinitis.	April, 1902.	Not given. . .	Eyes not improved much.	Lived 7½ mos. 11, 1, '02.	Was a desperate case from the beginning.	A. C. Bernays, St. Louis.
11	M., 20	About 1 year ago	Bilateral interstitial.	Mild optic neuritis with few hemorrhages.	11, 10, '02 .	Cardiac involvement.	Temporary improvement.	Died 11, 17, '02.	Dr. O. performed a decapsulation on one kidney prior to 11, 10, '02; died of acute suppress. of urine and uremia	Ochsner and Suker, Chicago
12	(?)	. . . . .	As above	Album. ret., glistening spots (not characteristic). V reduced.	. . . . . .	Cardiac hypertrophy.(?)	Died within a few days (4 days).	Fatal	Was a desperate case, almost moribund when brought to hospital.	Munro, Boston.
13	M., 29	Jan. 15, 1903.	As above . .	Silvery spots in macula. light streaks along arteries, V *poor.*	1, 27, '03.. .	Not given(?) . .	Improved for a time.	Losing ground rapidly. Died *in June 1903.*	General condition improved some but eye symptoms not as a subsequent examination showed.	Munro.
14	M., 51	1885(?) . .	Bilat. chron. diffuse.	Failing eyesight, ret. album.(?)	6, 2, '02. . .	Varying am'ts of edema.	Good	Improved, living, 1, 19, '03, eyes no report.	This is Dr. Edebohls' case No. 37. (If this is a true case of retinitis albuminurica of so many years standing, it is one of the wonders.—G.F.S.)	Edebohls.
15	M., 23	Dec. 21. 1901.	Bilateral interstitial.	Sudden blindness, Dec., '01	4, , '92.. .	Mitral regurg., hypertrophy heart.	Not good; lived 8 days.	Died 4, 19, '02..	Died of uremia and exhaustion. Case No. 24.	Edebohls

1. The record "*fatal*" means that the patient died within 8 to 72 hours after the operation. The majority were bilateral decapsulations. Ries and Ochsner operated on one kidney and later on the other. Edebohls usually decapsulated both kidneys at one sitting.

2. C. A. Oliver is conducting a series of experiments to determine the effects of the operation on the amount of albumin in the aqueous humor.

3. Cases Nos. 6 and 14 can be excluded in drawing definite conclusions, because No. 6 died of an intercurrent disease and No. 14 has lived so long with a supposed albuminuric retinitis that perhaps the retinal trouble is of a different nature (advisedly stated).

4. The visual fields were taken in Ries and Ochsner's cases. In all (3 cases) it increased after operation.

5. The writer had the privilege of examining and watching the cases of Ries, Gradle and Ochsner, both before and after operation. These were typical cases in every particular, and therefore of great value in this statistic.

6. Some cases had blood casts, most of them presented hyaline and granular casts, a few had erythrocytes in the urine.

7. Ries has made many microscopic sections of the kidney after operation, but failed to find increased vascular anastomosis. Zeit, ibidem (personal communication).

8. The operation did not prolong life. The medical treatment offers a better *percentage* as far as prolonging life is concerned.

9. Since reading this paper the writer has obtained 4 more cases which were typical and submitted to the operation; they died within a few months thereafter.

10. Excluding the two cases, Nos. 6 and 14, the mortality rate is 99 per cent. What a showing in 17 cases!

NARRATION OF CASE.

Mrs. L. (operated on by Dr. Ries, Chicago).

Diagnosis.—Neuroretinitis albuminurica; chronic interstitial nephritis with rather marked cardiovascular implications.

Fundus Findings.—Disseminated albuminuric spots of the inflammatory type throughout the retina; the veins were engorged and the arteries very much attenuated. The retina was spattered with small flame-shaped hemorrhages. The macular region was fairly free. The optic disc was very imperfectly outlined, due to the neuritis and the swelling; it equaled about 2 mm. Both eyes were about alike as to the changes present. V.=20/60 in each eye March 29, 1902. The field of vision *on this day concentrically* contracted as seen in the chart (Fig. 1).

April 23, 1902 (not quite four weeks after the capsulotomy) the nerve head could readily be outlined. The retinal hemorrhages had disappeared and the whole retina was greatly improved. The field of vision was materially enlarged (Fig. 1) and the acuity was: O.D.V. 20/40+3. O.S.V. 20/40+2.

At time of death (August, 1902) she was reported to have had practically normal vision. The cause of death was peritonitis. (For further particulars as regards the disappearance of albumin and its return after the operation in this case see reports of Ries.)

The period of time that is regarded necessary to pass before the operation is considered as having produced a cure is six months, according to Edebohls. At the end of this time the urine must be free from albumin and remain so. But few of the cases with retinal complications outlived this period. The majority improved to some extent, both as to vision and urine, still the relapse came on rapidly in both organs and the patients died. True, in a few instances the improvement of the eye condition was almost miraculous. We know that even with the medicinal treatment marked temporary improvements take place and may even continue for some time. All the cases with eye symptoms, except one, died within the first year. The greater share, if not all, had a bilateral kidney and eye lesion and perhaps always bilateral at death. The majority gave decided evidences of cardiac involvement. The kidney lesion in each instance was a *chronic interstitial or diffuse nephritis*, or an acute attack on top of a chronic condition. The successes so far reported for decapsulation were for the uncomplicated chronic nephritis. Whether or not the operation in any way hastened the exitus in the cases reported here is certainly very problematical, for they nearly all came, as it were, under the "two-year clause." The operation, in competent hands, is practically devoid of any dangers (kidney and life).

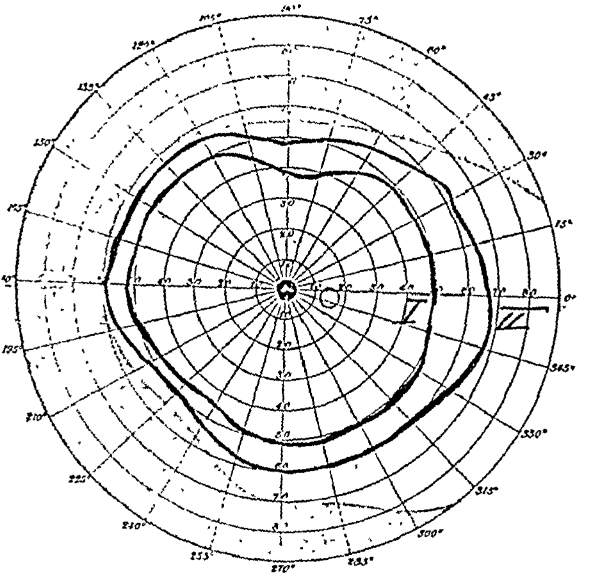

Fig. 1.—Mrs. L. I. Visual field on March 29, 1902, two days prior to the operation. II. Visual field April 23, 1902, about four weeks after the operation. The left field is practically the same as right. No scotomata in either field.

The mere fact that the general condition of the patient improved slightly after the operation does not establish its validity. For we know that often in not doing anything, excepting advising hygiene, marked improvements both as to sight and kidney take place.

If we could have an interstitial nephritis definitely limited to one kidney, though with more or less fundus involvement, the operation might, if performed early, be of great benefit. This can be partially supported by the fact that some uncomplicated cases of nephritis have survived the operation for a period of 3 to 10 years (see Edebohls). Knowing that the retinal manifestation indicates a very firm establishment of the nephritis and that a serious cardiac involvement is almost a constant factor, it does seem that the operation offers no ray of hope, either as a cure or as a permanent amelioration. The statistics pertinently show this point to be true. As fundus complications are so frequent in interstitial nephritis, it may be asked whether kidney decapsulation will prevent them if done very early. This is problematical. The exact limits beyond which the operation in any case, simple or complicated, will or will not fail to accomplish any good has not been determined. As far as albuminuric retinitis is concerned, all that can be said is that the results have been decidedly temporary, and this in nearly every instance.

In conclusion, we may recapitulate as follows:

1. The operation of decapsulation so far is not warranted in all instances, nor does it offer any hope in cases of bilateral chronic nephritis with retinal complications.

2. Though there is an improvement in the eye ground directly after the operation, still it is decidedly temporary, judging from the present statistics.

3. *The operation may be of service in unilateral* nephritis with fundus lesions in the initiatory stages. These cases, however, are rare, and, if found, soon become bilateral. Therefore, these latter cases would come under the first remark.

4. The mortality rate for albuminuric retinitis in chronic nephritis has not been lessened by the operation.

5. The statistics show that retinal complications are a decided index as to the severity of the kidney involvement.

6. In nearly all the cases of nephritis chronica the cardiac involvement is present and is an important prognostic factor. With the retinal lesion, it is usually present.

7. Unilateral retinal lesions are the exception in chronic nephritis.

8. As yet the medical treatment of all these cases yields as good results, if not a trifle better, than the kidney decapsulation.

9. Statistics of the mortality rate of albuminuric retinitis based on urethral catheterization are indicated. This is to determine whether those that outlive the two-year period might be cases of unilateral nephritis or are late in becoming bilateral.

The writer wishes to take this opportunity to express his gratitude to the various gentlemen who answered the circular letter in reference to this subject. In particular does he wish to acknowledge the courtesies of Drs. Ries, Gradle, Ochsner and Dodd of Chicago, Oliver of Philadelphia, Munro of Boston, Bernays of St. Louis, and Edebohls of New York.

DISCUSSION

ON PAPERS OF DRS. STRICKER AND SUKER.*

Dr. Henry Dickson Bruns, New Orleans—Dr. Stricker is entirely right in holding that the proportion of urea excreted in the urine is of far greater significance than the presence in the same fluid of more or less albumin. The general practitioner was somewhat slow in recognizing this truth and making practical use of it; it is not to be wondered at, therefore, that the oculist should have been still slower. To-day, however, I believe that all physicians of the first rank accept and act on it in the study and treatment of their cases of renal disease. They all, too, hold to the belief that it is the retention of the excrementitious products, of which the urea in the urine is the expression, that produces the lesions found during disease of the kidneys; the escape of albumin into the urine being a symptom of more or less importance according to the *presence or absence of a host of other phenomena*. Nor have the ophthalmologists followed far behind, as the passage cited by Dr. Stricker from Professor Leber, published twenty-six years ago and containing a citation from Von Graefe, plainly shows. Dr. de Schweinitz,[1] quoting J. B. Lawford, says: "Uremic amaurosis may occur in any of the various forms of renal disease in which there is sufficient interference with the function of the kidneys to load the blood with those poisonous materials, whatever their exact nature may be, which induce the uremic condition." And, again, that retinitis, retinal hemorrhages, etc., may precede albuminuria by a considerable time. It is probable, as Dr. Sutton suggests, that these are examples of granular kidney, in which albumin is absent, or only present to a very small extent until a later stage of the kidney affection. On the other hand, the lesions which I have described as occurring in the blood vessels, particularly various types of perivasculitis, and of "silver-wire" arteries, producing compression on underlying and overlying veins, are often present for long periods before the renal lesions are manifest, or at least before the other signs of renal disease are fully established; that is, albumin and casts. These expressions certainly indicate a belief that the excrementitious products are the injurious agents. So in a paper by Dr. S. C. Ayers[2] we read: "The question of the diminished excretion of urea is not a new one. Dr. S. Marx,[3] in a very interesting paper, states that this condition arises not from albumin, but from diminished excretion of urea. He states that many women with grave nephritic disease go to full term with little or no discomfort. He further states that albumin and casts have no meaning for him in the presence of a normal urea excretion, for with that he is in a position to know that sufficient of the effete products are being excreted and the condition of the safety valve in the engine of the body is evidenced by the behavior of this element. Whether this urea is really the offending agent or not, modern investigation does not allow us to state with any degree of positiveness. It is enough to this end to state that when there is a lessened secretion the patient suffers, and when hypersecretion occurs the patient is freed from those symptoms to us indicative of toxemia. Dr. E. E. Morse of Washington, D. C., endorses the theory of Dr. Marx. Dr. Stricker, then, deserves our thanks for bringing this subject to our attention at this meeting and emphasizing the necessity of observing whether or not the vision and other ocular symptoms vary with the fluctuations of the amount of urea excreted. His position as to the indications in the albuminuria of pregnancy seems eminently correct, but one must not be too sure that in every such case "the kidney disease will subside quickly after labor is terminated." I once saw a case where albuminuria had been recognized only after the pregnancy had begun. Shortly after the birth of her child the patient became quite blind, and I was called in. The eyes showed typical Brightic changes. The patient did well for a few days, but then fell into convulsions and coma, and died. The fact that vision may improve even to the normal in any form of Brightic retinitis, although there may be little, if any, change in the ophthalmoscopic appearances, may now be taken as established. A case (No. 11) reported by Dr. C. S. Ayers[2] would go to prove that even extensive degenerative changes may clear up, though this is unusual, if time enough be afforded. In Dr. Ayer's case the patient had had nine pregnancies. In the fourth, fifth, sixth, seventh and ninth there had been failure of vision. Premature delivery occurred in the seventh month of the ninth pregnancy, and her eyes were examined some time after; the right equaled 0.1 and the left equaled 0.7. There were characteristic alterations in each eye and numerous white patches in the retina of the left. Twelve years afterward he found the right eye perfect; L. E. V. equaled 20/xl, but with +0.75 cyl. ax. 110 degrees it equaled 1. The retina looked normal and healthy, and there was no trace of patches. While there is no etiologic connection established between senile cataract and albuminuria in premature cataract—cataract occurring in middle life—the urine should always be examined. Finally, perhaps, I may be permitted to say that while pathologist of the Charity Hospital, as many as ten years ago, the fallacious nature of albuminuria as an evidence of renal disease was forced on my attention by the not infrequent finding of casts in urine showing freedom from albumin by the most delicate tests. In a series[4] of 2,441 first examinations, casts without albumin were found 40 times—about once in 61 times. The kinds of casts were: Epithelial in 1 instance, granular in 4, hyaline in 14 and unrecorded in 21 instances.

---

* The paper of Dr. Stricker appeared in The Journal February 20, p. 514.

Dr. Allen Greenwood, Boston—A large number of these cases should be considered from the standpoint of arterial degeneration, rather than from the standpoint of kidney disease. I classify my cases in two groups: one, the aged people with general arterial degeneration, in whom you find degeneration of the arteries of the retina and choroid sometimes before there is evidence of kidney lesion; and the other, in the young and middle-aged, where you have distinct chronic parenchymatous nephritis with retinal changes and death in a few years. In the last twelve years I have seen 26 cases in private practice, and have followed all but 2 to the ultimate end. Out of the 26 cases only 3 are living, and none of the 3 living was seen prior to two and a half years ago. I think physicians and surgeons make a mistake in not having the eyes of their patients examined more frequently. All the cases of kidney disease at the Boston City Hospital are, during my service, referred to me for ocular examination. Just before death retinal changes are nearly always present.

Dr. Leartus Connor, Detroit—Why is it that we have patients with deficient excretion of urea, and with albumin and casts in the urine, but yet it is only occasionally that we have these ocular complications? What is in these particular cases different from the others? I do not think we can answer the question except by referring it to the personal equation of the individual, something in the structure of the retina of the one. This is yet to be worked out. The same thing confronts us in many other morbid conditions. Why should there be this difference in urea excretion? What are these excrementitious products? What are these toxins? We have known for some time that in a pregnant person such ocular complications mean death in a short time, but why the complications occur in one individual and not in another, we do not know.

Dr. Edward Jackson, Denver—I think there can be no question as to agreement with Dr. Stricker that not albumin, but deficient elimination of urea, is the factor of importance. My experience would point out that why one patient has retinal lesions and another has not depends on the condition of the general vascular system. I have never seen a typical case of albuminuric retinitis without involvement of the vessels generally. But sometimes where I have found slight lesions of the disc and retina and decided changes in the vessels, careful and repeated examination has failed to show any changes in the urine. The retinal lesions are associated with vascular changes. This leaves a small loophole for the surgeons who urge decapsulation. The cases that present retinal lesions are evidently not saved, so far as our statistics indicate; but possibly there is a class of cases of chronic nephritis that do not have retinal lesions and are not liable to have them, that may be helped by the operation. But so far as those cases are concerned about which we can form a prognosis, his paper indicates that they are not permanently helped.

Dr. G. E. de Schweinitz, Philadelphia—While it is true, in general terms, that ocular lesions may occur with any form of nephritis, the various types of retinitis are most frequently associated with chronic interstitial nephritis (that is, with renal sclerosis), whether this is an independent primary affection, or whether it is a sequel of arteriosclerosis. It seems to me undoubtedly true, as Samuel West has recently insisted, that a sharp distinction should be made between the degenerative and exudative forms of albuminuric retinitis. The former indicate the presence of chronic granular nephritis, and the degenerative changes depend on vascular alterations. The latter indicate a chronic parenchymatous nephritis and probably depend on an inflammatory or toxic influence. To put this in other words, albuminuric retinitis of the degenerative type is a symptom of vascular changes, which in their turn are widespread throughout the body, and not necessarily a symptom of kidney disease itself as an isolated condition; that is, the nephritis and the retinitis are both caused by the vascular lesions. Doubtless, Dr. Jackson is correct in stating that in the great majority of instances it is possible, ophthalmoscopically, to see lesions in the retinal vessels no matter what the type of the so-called renal retinitis may be, but none the less I am persuaded that the distinction before referred to is worthy of consideration.

[3] Med. Record, April 20, 1901.

[4] "Notes on Examination of the Urine," by H. D. Bruns, M.D., Med. News, Sept. 7, 1895.

DR. O. A. GRIFFIN, Ann Arbor, Mich.—A recent case of albuminuric retinitis proved interesting because of its sudden development and early termination. A woman about 60 years of age had her hip fractured and her physician made repeated examinations of her urine with negative results. About five months later she became suddenly partially blind, the condition being attributed to a general debility. Two weeks later I was called and found that the vision could not be materially improved by lenses. An examination revealed the characteristic fundus changes, and on testing the urine a large amount of albumin was found. The case was then referred back to her physician, but treatment was of little avail, death occurring within seven months.

DR. LOUIS STRICKER, Cincinnati—I would not like to leave any one under the impression that I do not recognize that a certain number of cases are the results of vascular changes. They result from the general vascular fibrosis, which is present all over the body, but I believe that the majority, including most typical cases, are not those of vascular changes, but are consequent on toxemia. I might say that the fibrosis is in all probability due to toxemia. True, where we get closure of the vessels, it is but natural that necrotic changes and hemorrhages follow, but the typical conditions are due to toxemia. Recently a woman came to me with a pure neuritis. I found her urea quantity one-tenth normal, and put her on treatment for Bright's disease, sweating her freely. This was not a typical case of neuroretinitis Brightica, but while she was under treatment in the hospital, as I observed her from day to day, this typical picture did develop. In spite of the treatment, the necrotic conditions went on. This was not a vascular change, but was undoubtedly the result of chemical irritants in the blood, the pure toxemia. These toxins do not come from the kidneys. The supposition is that they are the result of an imperfect metabolism, a break in the chain leading up to a perfect conversion of proteids into uric acid and urea in the liver. Where this conversion is interfered with, the toxins develop. Just what these are we are unable to state, but one thing is sure: when urea fails of perfect excretion from the kidneys, either this as such or the toxins produced remain in the system and are the causative factor of inflammation. I would again repeat, greater stress is to be laid on the reduction of the urea below the normal in the urine than on the presence of albumin; and this is a point which all text-books on the eye fail to recognize. Albumin in the urine simply indicates that the kidneys permit it to escape; that they are diseased, but loss of albumin does not produce eye disease. These diseases, I take it, are not the result of anemia, but of chemical irritants or poison circulating in the blood. One of the latest works on obstetrics advances the idea that the Bright's disease of pregnancy is due to the impaired action on the part of the liver. I do not see how the taking off of the capsule and tearing the kidney tissue is going to do any good. I appreciate that the removal of tension can give the kidney a chance to regain its function, but this could only be of service in acute cases; beside, the operation is surely an extremely dangerous one, and I, for one, would hesitate to use it.

DR. GEORGE F. SUKER, Chicago—Dr. Edebohls is operating on a great variety of cases, including even puerperal eclampsia. Whether or not the operation is indicated in all the classes of nephritic lesions is certainly an open question. One must carefully weight the advisability of suggesting the operation in any form of albuminuric retinitis. From the statistics given in the paper, one can hardly see any justification for the operation in chronic forms of nephritis with retinal lesions. The operation has not been tried in a sufficient number of cases of acute nephritis with retinal lesions to be of any value in deciding its justification. Again, the indication for the operation must to a certain degree depend on the fact whether the Bright's disease is a pure nephritic lesion or is due to a general arteriosclerosis. If the latter, the operation can accomplish little; but a good deal if due to the former cause. As yet, it is too early to render a final opinion whether the operation is justifiable in cases of nephritis with fundus lesions. Still, we have no right to discard the operation without giving it a fair and extended trial in well-selected cases.

SOME REMARKS CONCERNING THE OCULAR AND AURAL REQUIREMENTS OF RAILROAD EMPLOYES.[*]

FRANK ALLPORT, M.D.
Professor of Clinical Ophthalmology and Otology in the Medical Department of the Northwestern University; Eye and Ear Surgeon to the Chicago & Northwestern Railway, Chicago & Eastern Illinois Railway.
CHICAGO.

Some three years ago the Interstate Commerce Commission published an interesting report of railway accidents occurring in the United States in one brief year. There is no reason to suppose that this was an especially unfortunate year, and as the figures are instructive and full of significance, I will quote some of them.

The total number of personal accidents was 51,743, and of these 7,123 were killed, 2,210 being railway employes; 334 employes were killed and 2,153 injured by collisions and derailment, and 82 passengers were killed and 1,557 passengers injured from the same cause.

The causes of these accidents are doubtless numerous, but have not been, so far as I am aware, statistically enumerated, although such tabulation would be most interesting and instructive. A small minority of the accidents were perhaps in the ordinary course of events unavoidable, but a large majority were probably preventable, and due to carelessness or physical defects on the part of train operators. Of such physical defects it is reasonable to suppose that ocular and aural defects, especially the former, played a most important part, for no physical condition, except the mental condition, is so intimately connected with the moving of a train as vision. The eyes are continually in service—watching for signals, both luminous and non-luminous, looking at the track and searching for approaching trains, familiar objects, etc., etc. In short, there is not a moment during the active operation of a train that the engineer and his fireman have not a vital interest in good vision, and the same is true in a mitigated sense of the conductor, brakemen, switchmen, bridgemen, etc.

I am confident that if statistics could be gathered of the accidents caused by bad eyes, even for a single year, the showing would be so appalling that every intelligent railway official would require no further incentive to perfect the ocular status of his men.

In order to ascertain what was being done to regulate this important essential to transportation security, some years ago a committee, of which I was chairman, was appointed by the Section on Ophthalmology of the American Medical Association, to investigate this matter and report back to the Section. Owing to many obstacles, the Committee was not able to report finally until the year 1901 at the St. Paul meeting of the Association. Meanwhile we gathered statistics which have proven of immense value in placing the work on a solid foundation.

---

[*] Read before the American Academy of Railway Surgeons, Oct. 1, 1903.

Letters of inquiry and a question blank were sent to every railroad in North America possessing over 100 miles of road, and 244 companies were thus addressed, operating a total of 205,638 miles. One hundred and twelve roads replied, aggregating 147,838 miles of road. These figures represent almost all the large systems, for those not replying were principally the small railroads, many of whom have now been merged into the larger systems. I found that out of 112 roads, 77 require some kind of a systematic eye and ear examination of those employes who are actively engaged in running trains and in giving and receiving signals; 29 of the roads require such examinations to be made by regularly appointed railway surgeons; 31 allow various kinds of railway employes to make the examinations; 9 roads send doubtful cases to an eye and ear surgeon; 16 roads require examinations to be made by regularly appointed eye and ear surgeons, and 4 allow such examinations to be made by the medical directors of railway associations.

In answer to the question: "Do you require re-examination from time to time, and if so at what interval or under what circumstances?" I find that 1 road requires re-examination every six months; 7 roads require re-examinations every year; 21 roads every two years; 9 roads every three years; 2 roads every four years; 19 roads require re-examinations when it is deemed advisable, and especially on promotion and after accidents and illness; 3 roads require re-examination on promotion only.

Concerning the question: "Do you require perfect vision, color sense and hearing in new employes, and what concessions do you permit from a perfect standard in the case of old employes?" I find that 26 roads require perfection and allow no concessions to old employes; 41 roads require perfection from new employes and allow, according to circumstances, various concessions to old employes.

Concerning the question: "How long must a man work for your road before you call him an old employe?" I find that 2 roads call a man an old employe as soon as he is enrolled in the service; 7 roads require one year service; 3 roads two years' service; 12 roads three years; 12 roads five years; 7 roads ten years; 3 roads fifteen years.

Concerning the question: "Do you permit old employes to wear glasses for distance when on duty?" I find that no road allows new applicants to wear glasses for distance in order to bring vision up to a normal standard; 74 roads allow old employes to wear glasses for distance; 12 roads do not allow glasses to be worn for distance at all.

The report of the committee which was presented at the St. Paul meeting was as follows:

SECTION 1. The essential principle to be advocated is that railroad corporations shall require a scientific and correct examination of the eyes and ears of those employes at all to be concerned with the active operating of trains, or in giving or receiving signals.

SEC. 2. Such primary examinations should, whenever possible, be made by regularly appointed eye and ear surgeons, and this fact is emphatically urged, especially as the expense of a first examination may always be borne by the applicant; but if such a course is not deemed expedient, the company's surgeon, aided by his medical assistants, might conduct them, with the understanding that all doubtful cases shall be sent to a regularly appointed eye and ear surgeon.

SEC. 3. There shall be two general standards of visual and aural requirements, viz.; those for new men hoping to enter the service, and to be actively engaged in the operation of trains, and in giving and receiving signals; and, secondly, those men engaged in similar work, who have been uninterruptedly in a company's service for five years, and who have, therefore, a right to be called "old" employes.

SEC. 4. New men shall be required to possess perfect color sense. They shall also have a vision of 20/20 in each eye, without glasses, and have healthy eyes, and not over one diopter of hypertropia. They shall also hear the whispered voice at 20 feet in a quiet room, and have healthy ears.

SEC. 5. For the purpose of graduated requirements, old employes shall be divided into two classes, as follows: Class A—Engineers, firemen, conductors, brakemen, switchmen, signalmen, switchtenders and engine dispatchers. Class B—Track foremen, bridge foremen, crossing flagmen, bridgetenders, gatemen, train baggagemen, telegraph operators, station agents, and station baggagemen.

Employes enumerated in Class A shall not be retained in such positions if vision sinks below 20/30 in one eye and 20/40 in the other, or if the whispered voice can not be heard in a quiet room at 15 feet by one ear and 10 feet by the other. Employes enumerated in Class B shall not be retained in such positions if vision sinks below 20/40 in one eye and 20/50 in the other, or if the whispered voice can not be heard in a quiet room at ten feet by both ears. Employes, and especially engineers and firemen, enumerated in Class A must reach the visual standard without glasses and will not be allowed to wear distance glasses when on duty. Employes enumerated in Class B may reach the visual standard with glasses, and will be allowed to wear glasses when on duty, and will be required to do so if the wearing of glasses is necessary to bring vision up to the proper standard, and shall always be required to carry an extra pair of glasses when on duty, in case of accident to one pair. All employes shall have perfect color sense.

SEC. 6. Re-examination shall be made of all men every three years, and after a severe illness, or accident, or any occurrence which seems to cast doubt on the visual and aural capacities of the individual. Re-examinations shall also be made more frequently on men known to be excessive users of tobacco, or to be suffering from syphilis, albuminuria, diabetes, or acute or chronic eye and ear diseases. Men shall always be re-examined before promotion.

SEC. 7. Men known to be excessive users of liquor shall not receive employment.

This report was adopted by the Section on Ophthalmology, and the Committee requested to present it to the House of Delegates of the American Medical Association at its next meeting at Saratoga, which was accordingly accomplished. Owing to some diversities of opinion, the resolutions as presented in the Section on Ophthalmology had to be remodeled in order to insure their passage. The resolutions as remodeled, I now beg leave to present:

SECTION 1. It is essential that railroad corporations should require definite and scientific examinations of the sight and hearing of those employes who will be at all concerned with the active operating of trains or in the giving or receiving signals.

SEC. 2. Such examinations should, whenever possible, be made by regularly appointed eye and ear surgeons; and in all cases be conducted according to the instructions, and under the supervision of a regularly appointed eye and ear surgeon, and with apparatus and under conditions approved by him, and all doubtful cases should be referred to him for personal examination.

SEC. 3. New men should be required to hear the spoken voice at 20 feet in a quiet room, and have healthy ears.

SEC 4. The acuteness of vision should be tested by the test types of Professor Snellen, or those which conform to the standards.

SEC. 5. The following minimum requirements should be adopted for acuteness of vision:

CLASS A.		
	ENTRANCE TO SERVICE OR PROMOTION.	RE-EXAMINATION OF THOSE IN THE SERVICE.
Enginemen (road service). Firemen (road service).	20/20 in each eye tested separately without glasses.	20/30 with both eyes open, without glasses. Each eye should also be tested separately and the vision of each noted.
CLASS B.		
Other employes in the engine, train or yard service, and car and engine inspectors.	20/20 in one eye and not less than 20/40 in the other, tested separately without glasses.	20/40 with both eyes open without glasses. Each eye should also be tested separately and the vision of each noted.
CLASS C.		
Towermen, telegraph operators, station agents, section foremen.	20/20 in one eye and not less than 20/40 in the other. Tested separately with or without glasses.	20/40 with both eyes open, with or without glasses. Each eye should also be tested separately and the vision of each noted.
CLASS D.		
Crossing Flagmen.	20/40 with both eyes open, with or without glasses.	20/50 with both eyes open, with or without glasses.

SEC. 6. The color perception should be tested by means of the colored worsteds of Professor Holmgren, preferably with worsteds tagged with the purpose of record; also, that in every case an additional test should be made with a lantern showing a number of colored lights, which can be varied in their size and intensity.

SEC. 7. (*a*) Employes enumerated in Class A must reach the visual standard without glasses and should not be allowed to wear distance glasses when on duty.

(*b*) Employes enumerated in Classes B, C and D should be allowed to wear glasses when on duty, and should be required to do so if the wearing of glasses is necessary to bring the vision up to the proper standard. They should also be required to carry an extra pair of glasses when on duty, in case of accident to one pair.

(*c*) Employes enumerated in Class A should not be retained in such positions if the vision sinks below 20/30 with both eyes open, or if the spoken voice is not heard in a quiet room at 15 feet.

(*d*) Employes enumerated in Classes B and C should not be retained in such positions if the vision sinks below 20/40 with both eyes open, and Class D, whose minimum standard should be 20/50; or if the voice can not be heard in a quiet room at 10 feet by both ears.

SEC. 8. There should be two general standards of visual and aural requirements, viz.: One for men hoping to enter the service, and to be actively engaged in the operating of trains, and in giving and receiving signals; and one for those men engaged in similar work who have been uninterruptedly in a company's service for five years, either the company from which employment is sought, or some other company enforcing similar regulations. These latter may be regarded as old employes.

SEC. 9. Re-examinations should be made of all such employes every three years; and after any severe illness, or accident, or any occurrence which seems to cast doubt on the visual and aural capacity of the individual. Re-examinations should also be made more frequently on men known to be excessive users of tobacco, or to be suffering from syphilis, albuminuria, diabetes, or acute or chronic eye or ear diseases. They should always be examined before promotion.

SEC. 10. Men known to be excessive users of liquor should not receive employment for the services above designated (Section 5). The co-operation of the employes themselves should be sought by regulations that will encourage them to report promptly any temporary impairment of vision or hearing.

These resolutions have been sent to every railroad in North America, and have already accomplished an immense amount of good. Many companies which have never taken up this work at all, have expressed a determination to put it into execution at once, and others who have been using inferior methods express themselves as intending to improve such methods along the lines indicated.

There are a few important points of difference between the report of the Committee adopted by the Section on Ophthalmology and that adopted by the House of Delegates of the American Medical Association. For instance: In Section 2 the Section on Ophthalmology report reads: "Such primary examinations should, whenever possible, be made by regularly appointed eye and ear surgeons," etc. The same section as adopted by the House of Delegates, reads: "Such examinations," etc. The Section on Ophthalmology felt that it did not wish to draw the lines too hard on the railroads, and therefore use the word "primary," feeling that if the first or entrance examinations were made by the company's eye and ear surgeon, that the subsequent examinations might with reasonable safety be left with the company's surgeons for execution, with the understanding that doubtful cases would be referred to the company's eye and ear surgeon for decision.

Section 3 of the Section on Ophthalmology report corresponds with Section 8 of the House of Delegates' report, and I have no hesitation in saying that I regard one feature of the latter report as superior to the former, viz., the clause which refers to the interchangeableness of positions from one road to another whose requirements are similar, without losing the right to be regarded as an old employe. I am convinced that a man who has undergone primary examinations for one road and been accepted and placed at work, should be able to go to work for another road whose physical requirements are essentially similar, without losing the benefits of his time privileges. This feature of Section 8 of the House of Delegates' report I cordially indorse and hope it may become generally operative.

I find no reference in the House of Delegates' report concerning the requirements for the color sense except as found in Section 6, which contains nothing of an obligatory or mandatory character. The only explanation for this omission is of course the presumption that it is an oversight, and I should recommend that a clause be inserted in Section 5 of House of Delegates' report, after the words "acuteness of vision," to read as follows: "It being understood that all employes at all concerned in the active operating of trains, and in giving or receiving signals, should have perfect color sense."

Under Section 5, House of Delegates' report, under the requirements for re-examinations of those in the service "belonging to Class A," it says: "That the employe shall possess a vision of 20/30 with both eyes open, without glasses. Each eye should also be tested separately and the vision of each noted." This opens a wide avenue of discussion. The report of the Section on Ophthalmology concerning this same point, says that "Employes enumerated in Class A shall not be retained in such positions if vision sinks below 20/30 in one eye and 20/40 in the other." In other words, a reasonable standard is required of each eye, and it seems as if this must appeal to the judgment of anyone at all familiar with such work. Would anyone in this society care to travel on a train at the rate of 50 or 60 miles an hour with an engineer wearing a glass eye? I think not; the idea is untenable, and yet this is exactly what the House of Delegates' report permits, for it says that vision must be 20/30 with both eyes open. To be sure, it also says: "Each eye should be tested separately, and the vision of each noted," but it goes no further. It does not inflict any penalty in case an engineer has one blind eye. While disposed to be most liberal with the old employes of a road, and while recognizing its advisability and almost necessity if good service and freedom from labor union complications are to be encouraged, I still can not indorse the idea of testing with both eyes open, and of ignoring the condition of a man's worst eye. The idea is evidently conceived from the action of the International Congress, which met in Amsterdam in 1879, and which in formulating rules for the ocular condition of transportation employes, under the guidance of Professor Donders, repeatedly speaks of testing with "both eyes open." This was evidently recommended, because it is well known that one eye assists the other to see, and the Committee desired to treat all employes with all possible clemency, but they did not in their recommendations ignore the condition of either eye. For instance, in the case of engineers and firemen, while visual acuteness with both eyes open must be normal, still the worst eye must have visual acuteness of not less than one-half. Stationmasters, etc., must have a vision in the worst eye of not less than one-quarter, etc., so that the recommendations of the House of Delegates in absolutely ignoring the visual capacity of the worst eye in case of re-examinations seem to so far transgress the laws of good judgment as to make it only reasonable that this feature should be amended.

In making such amendments, I feel that several things should be considered, and while being, perhaps, as anxious for the maintenance of a high standard as anyone, and while unwaveringly insisting on perfection in the case of new employes, I increasingly feel that we must be most liberal in our concessions to old employes, and the older they are, and the longer they have worked for a certain company, the more liberal must we be. This conclusion has been reached after a long and extensive experience with railroad men, and while feeling that public safety must always be subserved—and it would be most beautiful if ideal and altruistic conditions might always be obtained—we, nevertheless, can not entirely ignore the practical issues of the problem. For instance: Here is an engineer who has worked in this capacity for forty years for a single company. He is an old man of much experience and excellent judgment, and has never had an accident that could be attributed to poor vision; and yet, nevertheless, has now a vision which has become reduced to 20/70 in one eye and 20/50 in the other, without glasses. When his vision is corrected with glasses his vision can be improved to say 20/40 in one eye and 20/30 in the other. Now let me ask you, what are you going to do with that man? This is a question which must frequently be answered, because a large proportion of old engineers have poor vision and sooner or later must face this problem. I think in laying down rules for the solution of such a question, that great latitude must be observed and the utmost paucity of vision, consistent with actual safety of train service, must be liberally computed. In making such calculations we should likewise remember that we can never be certain that we are correct in our deductions. We are simply expressing our own opinions aided by the opinions of others, but we have no way of knowing whether we are really right or wrong. Therefore, we should not be too dogmatic in our ideas or too intolerant of the opinions of others. We should not fail to remember that as a man waxes in age he also usually waxes in experience and good judgment, and what he lacks in vision and other physical attributes he makes up in other qualities, nearly if not quite as valuable. Many of the best and most trusted engineers on all roads unfortunately possess very poor vision, and yet get into very little trouble, not because their vision is so poor, but because they are ripe with practical experience and wisdom. Then comes the question of glasses, or in other words, shall old engineers be allowed to wear glasses when on duty when glasses are necessary to bring vision up to the accepted standard? I do not say "proper" standard, but "accepted" standard, because no one knows the limits of a "proper" standard for an old engineer. Please observe that I do not recommend the same degree of latitude for firemen that I do for engineers, for obvious reasons. Firemen are usually young men and have not had the experience and do not possess the ripe judgment of engineers. They should, of course, possess perfect eyes before they become firemen, and this same standard or a very small departure from it should obtain when their re-examination for promotion as engineer occurs. After they have actually become engineers, they are entitled to the latitude already referred to in this paper. I sometimes feel that the visual requirements of engineers should be graduated from time to time in accordance with their age and years of service on an engine, but this solution of the problem appears to complicate a situation which we are endeavoring to clarify and simplify. It therefore seems best to state what we believe to be the extreme limits of visual safety for old engineers in the requirements, and then trust in the good judgment, and, if I may use the expression, "horse sense" of the company surgeon or oculist to settle each individual case on its respective merits without indulging in hair-splitting technicalities.

But to return to the question of the advisability of allowing engineers to wear distance glasses when on duty. My own mind has undergone several revulsions of opinion on this important question, sometimes believing it best and at other times entertaining different views. I have noticed one thing, however, that my strictest views are in evidence when I look at the subject theoretically, and my most liberal views come to the surface when I am compelled to pass judgment on an individual case. I believe that no one will contradict the statement that a large proportion of engineers past 55 years of age would fail in a strict visual test for distance unless they could avail themselves of the assistance of glasses. This means that at the very time when engineers are most valuable to a railroad company—at the very age they may be considered the safest guardians of life and property—they may be discharged, because their vision has fallen one point below a prescribed theoretical standard; and although glasses can perhaps give them perfectly normal vision on both sides, they may not be worn. I understand all of the arguments against the use of glasses. They become misty on cold and foggy days, sweaty on hot days, speckled with dirt and cinders; and yet when I come to judge on individual cases and see in my consulting room a fine looking manly man of perhaps 55 summers, erect in his bearing, with a fine long record for carefulness, skill, reliability and judgment, with no serious accident in his entire career of perhaps thirty years as an engineer for one company; with a family to support, and with absolutely nothing against him except a refractive error that lowers his visual capacity a little below the required standard, and whose vision can be restored to a normal, or nearly normal, standard by the use of glasses, I must say that the temptation is strong, and usually becomes overpowering, to give him the glasses and tell him to continue in his life's occupation, feeling that a man of this character can be trusted to take care of his glasses and keep out of trouble. I believe that most men here present would do the same; and if we have not the courage to live up to certain arbitrary rules, or if we conscientiously believe that such rules are too drastic, why not outline a wise and still liberal policy which we are willing to accept and then live up to it?

I question very much whether we have the right to enforce the requirements of overpowering character on old engineers at the present time. No strict requirements were in force years ago when these men were admitted to work for different roads. They were accepted with but little ceremony, and now they have grown old in the service, and I feel should be dealt with as leniently as is at all consistent with safety. It should, however, teach us that we can hardly be too strict in the admission of new men to the service, and I feel that no man should be allowed to commence work on an engine as a fireman, hoping some day to become an engineer, unless he is a practically perfect specimen of physical manhood, for we must remember that as years progress and age advances, physical infirmities become accentuated and the trifling defect of young manhood becomes the disqualifying condition of riper years. It is for this reason that I urge the non-acceptance of new firemen, who, notwithstanding that they possess a vision of 20/20 in each eye, yet have an apparent substantial hypermetropia of, let us say, one and one-half diopters, which, although easily overcome in young life by an active ciliary muscle, shows itself unmistakably as age advances and the muscle loses its power, under which circumstances vision drops to a lower and still lower standard until it becomes so poor that the man's occupation may be lost from a cause which, if detected on the entrance examination, would have saved him this bitter disappointment of his advancing years. In other words, in examining a man for his primary entrance to the service, we should look ahead many years.

Another phase of the matter which we can not afford to ignore is the labor problem. In these days of labor unions, when the removal of a single man, even though he is merely taken from one job and given another, is perhaps sufficient to tie up an entire railroad system and paralyze many industries, it may be well to be sure we are on safe grounds when we remove from his engine a superior engineer, even though he is simply shifted from one position to another, to which it is thought his physical defect better adapts him.

I would then recommend, for reasons already given, that the House of Delegates' report be further amended by inserting under "Class A" and also under the caption "Entrance to service or promotion," and after the words "20/20 in each eye, tested separately without glasses," the words "The applicant shall not possess more than one and one-half diopters of apparent hypermetropia."[1]

Under the heading of Class A, and under the caption "Re-examination of those in the service," I would recommend that all of the underlying words be stricken out and the idea of testing with both eyes open be done away with as being both inaccurate, misleading and unscientific, and the following words substituted:

Enginemen shall not be retained in their positions if vision sinks below 20/40 in one eye and 20/30 in the other, or 20/20 in one eye and 20/50 in the other. Distance glasses must be worn when on duty, provided such glasses are necessary in order to bring vision up to the required standard. Extreme indulgence and concessions shall only be made to old and trusted enginemen, at the discretion of the company surgeon, it being remembered that the best vision is desirable and that glasses are undesirable. Firemen shall not be eligible for promotion to enginemen if vision sinks below 20/20 in either eye without glasses, and shall not be retained as firemen if vision sinks below 20/30 in either eye without glasses. The whispered voice must be heard at not less than 15 feet in a quiet room.

Under the heading of Class B, "Re-examination of those in the service," in House of Delegates' report, instead of the words "20/40 with both eyes open," etc., I would suggest the words: "Employes shall not be retained in these positions if vision sinks below 20/40 in one eye and 20/30 in the other eye, or 20/20 in one eye and 20/50 in the other. Glasses must be worn if they are necessary to secure adequate vision. The whispered voice must be heard at not less than ten feet in a quiet room." I would suggest the same words in the same section of both Class C and Class D. I would recommend striking out entirely Section 7 in House of Delegates' report, as the points contained therein have been fully rehearsed before. On this account Section 8 should be called Section 7, Section 9 Section 8, and Section 10 Section 9.

I exceedingly dislike making these suggestions, which have developed into a good many, especially as I have in the past strongly advocated their general adoption. While recognizing their shortcomings, I am confident that as between the two reports the Section on Ophthalmology report is the better, and should not have been tampered with; as it was the deliberate result of the work of a conscientious Committee, extending over years, while the House of Delegates' report was the result of the quickly and illy considered debate of a few moments in the House of Delegates, where some little eloquence or personal influence goes a long ways in reaching results. I will gladly support either the Section on Ophthalmology report or the remodeled House of Delegates' report as contained in this paper. I am merely anxious to get some good and commendable movement thoroughly started in railroad circles, some ideas and instructions crystallized, which will be uniform throughout the length and breadth of this land and be accepted as a standard to work from. After this is accomplished, further improvements and advancements can be made, but we should be careful not to make our recommendations so strict and oppressive that they will be ignored.

---

[1] If the applicant can have a +1.00 diopter lens placed in front of each eye, separately tested, without blurring his vision, he has one diopter of apparent hypermetropia. If a +1.25 or a +1.50 diopter lens does not blur his vision he has more than one diopter of apparent hypermetropia.

Before closing, I wish to enter a plea for the more general appointment of eye and ear surgeons on the different roads and the investing in them of broader responsibilities. I feel confident that if more roads and their general surgeons sought the intimate counsel of skillful and conservative eye and ear surgeons, both as to accidents, examinations and advice concerning the policy of the road in matters about which they are supposed to be especially interested, it would be better for all parties concerned; or in other words, to use the language of Mr. R. C. Richards, the experienced and efficient general claim agent of the Chicago & Northwestern Railway: "Why would it not be a good plan to spend a small portion of the money that is paid out every year for safety appliances in getting some safety employes?"

92 State Street.

THE BLUE LIGHT TREATMENT IN DISEASES OF THE SKIN.

LOUIS E. SCHMIDT, M.Sc., M.D.
CHICAGO.

Roswell Park has but recently stated that the x-ray treatment is in its infancy and that its true value cannot be estimated at the present time, but that it is a matter of the future. The entire field of light therapy is still in an experimental stage and necessarily the results of treatment are open to criticism. Certainly with so many careful and earnest workers as are in the field at present, the evidence as to their value is just a question of time. Because there is a variance of opinion,[1] due to variance in the results of different workers in the same class of cases, it is not courteous nor scientific to accuse individuals who have the spirit of investigation and scientific interest at heart, of dishonesty whenever the results are not as good as those of others. Neither should it be done if the results are better. This will also hold true of phototherapy. Certain forms of the latter mode of treatment have been in use for a much longer time than radiotherapy. However, not any one method has been taken up with the same zest and interest as the x-ray method of treatment. Hence, as regards the number of cases treated there are but few compared to it, though the time which has elapsed is not sufficient to permit of final judgment as regards their value. On account of the similarity in action and results it may be pardonable to make some slight comparison. Other methods of phototherapy than the one mentioned in the title of this paper have been resurrected, others, devised but recently, have been brought forward into the field of therapeutics.

The red light treatment of Finsen was introduced almost fifteen years ago, but is now again in the experimental stage. Brilliant results were recorded in the first cases, but the latest investigators have failed to corroborate them, yet it is necessary to wait until further work has been done in this particular line. The red rays with which Finsen experimented undoubtedly have a tonic action on the nervous system; however, this form of treatment, in the diseases of the skin, depends on the exclusion of the chemical rays of the solar spectrum. Finsen, to be more exact, has shown in his studies of the acute exanthemata, good results. Yet numerous investigators have failed in the same class of cases to observe good results with the method. These red rays can penetrate deeper into the tissue than the blue rays, as shown by many workers. The blue rays show a decided action on the vasomotor system, and apparently have a soothing effect on individuals suffering from excitement, just opposite to the action of the red rays.

There are certain recognized facts, for instance, antagonism between the colors of both ends of the spectrum, and demonstrated by the following: The phosphorescence caused by the blue rays are overcome by those of the red light. Here the extremes have the opposite action. It can not be expected that this remains true in every instance, but that their peculiar action shows gradual differences. Finsen was the first to investigate the value of the light treatment and it was in connection with variola red light was used. Gen. Pleasanton, however, in an empirical manner, used blue light. The other colors of the spectrum have as yet not been used in phototherapy; certainly not in the field we are interested in.

Now as regards the topic under consideration. It was Minin who first used blue light, by using blue incandescent lamps and reflectors. Later it was modified until it attained its present form. Minin's, Marcus', and my own results have been obtained with the apparatus which I will describe. This consists of an arc lamp, back of which a reflector is placed. It is best to have a resistance box on whenever using the street current, in order to regulate the constancy of the light, which in our case is 5,000 candle-power. The reflector concentrates and throws the light on a screen, which consists of blue glass. The height of the screen can be regulated so that the desired parts of the patient, who is placed behind it, can be readily exposed. As the screen is of large size, large surfaces may be treated at the same time. In this it differs distinctly from the Finsen light treatment. The mode of treatment is as follows: It is not necessary to protect the healthy parts with metal sheets, as in x-ray work, when treating localized areas. Up to the present time no untoward effects have been noticed, though the entire body has been exposed. The parts exposed should be unprotected from clothing, etc. The distance from the screen should vary as to the case, depending on whether the heat rays should be used. The distance from the screen varies, therefore, from a few inches to a foot. As regards the length of time, this varies, depending on the distance, from a few minutes to thirty minutes, or even longer. The number of treatments differ, as in all other forms of light treatment. Some cases react readily, others react more slowly. Treatments may be given daily or twice daily for long periods of time. Here again it is not necessary to fear accumulative action as in the x-rays.

As regards the action of these particular rays after they have passed through the screen, they depend both on the heat and the color rays. The spectroscope shows the absorption of the red and yellow bands by the cobalt glass screen, while the blue and violet rays pass through. The ultraviolet also pass. The actinic action which accompanies the blue rays is much less than those accompanying the ultraviolet rays. Now as regards the action of the blue light. Are the blue rays of the spectrum bactericidal? Experiments of Bie and Finsen have shown that the action of the blue, violet and ultraviolet are the most powerful in the order named, hence this form of treatment should be considered favorably from this standpoint.

Which rays are accompanied by inflammatory reaction? According to the same investigators, they are the same rays that have a bactericidal reaction.

---

[1] For these various views as to the relative merits and shortcomings of the various forms of phototherapy and radiotherapy the current literature will be found to give the ideas of the many investigators.

Both in the blue light and Finsen light treatment one other question must be considered, and it is, "how is it possible, in the easiest and best manner, to free the rays from the undesirable heat rays without destroying at the same time the bactericidal and inflammation-causing action of the light rays?" This question is answered, in both instances, in different ways. In the Finsen method, whether or not glass or quartz lenses are used, again whether electric or sun light and again whether in the cooling of the rays distilled water or colored water is used, which also considers the absorption of some of the colors of the spectrum. In the mode of treatment under consideration the distance of the screen from the reflector and again the distance of the part treated from the screen, play a part in answering the question. As to the clinical action of the rays in the blue light treatment it has been possible for me to observe, immediately after the commencement of treatment, the appearance of oozing serum from ulcers, which in some cases becomes copious, stimulation of surfaces of ulcers causing rapid cicatrization, analgesic effects to painful skin diseases, and in some cases the allaying of severe itching, resorption of pustular and non-pustular nodules of the skin.

Number.	Name, Age, Sex.	Disease.	Treatment.			Space of Time.	Course.
			Kind.	No.	Length of Each.		
1	H., 32, M. .	Lupus vulgaris faciei et colli.	X-ray.	105	3 to 15 minutes. .	. . . . . .	For first few months apparent improvement, then but slight changes, for the new nodules constantly appearing, old areas however cicatrizing.
1	" " " . .	Same as above	Blue light. . .	15	15 " . .	27 days. . .	Immediate effect for the better, no new nodules at the periphery stopping of the progress, cicatrization.
2	I. M., 60, M . .	Lupus vulgaris faciei . .	X-ray.	114	3 to 20 " . .	. . . . . .	Dark bluish-red in color, distinct lupus nodules at periphery, much infiltration, great improvement but very slow.
2	" " " . .	Same as above	Blue light. .	17	10 to 30 " . .	30 days . .	[illegible] marked reduction of infiltrated [illegible] much lighter in color, scarcely [illegible]s at edges.
3	Miss W., 27, F.	Acne vulgaris faciei . . .	X-ray.	10	5 to 15 " . .	9 weeks .	[illegible] fter a period of rest, increase of [illegible] eatment was again taken up; [illegible]
3	" " "	Same as above	Blue light. . .	12	10 to 20 " . .	3 weeks . .	P[illegible] mprovement, lessening of congestion, but few fresh acne pustules appearing after commencement of treatment.
4	F. B., 21, M. .	Ulcus phagadenicus . . .	" "	4	15 to 30 " . .	7 days. . .	During course of first treatment pain lessened, appearance [illegible] ged. Base granulating [illegible] healing.
5	D. H., 47, M. .	Ulcus cruris	" "	6	15 to 30 " . .	2 weeks . .	Case [illegible] antiseptically for months. After commencement of treatment almost immediate improvement. At end of two weeks seat of ulcer covered with epidermis.
6	A. K., 19, M. .	Chron. vesicular papular eczema, both hands.	" "	15	10 to 20 " . .	3 weeks . .	Gradual but marked improvement. Vesicles after bursting apparently commenced to dry; scaling set in.
7	A. L., 30, M. . .	Carbuncle of neck	" "	21	10 to 20 " . .	4 weeks . .	Carbuncle size of silver dollar, marked lessening of pain, oozing of serum from broken-down tissue, rapid absorption of infiltration.
8	E. H., 22, F . .	Acne vulgaris faciei . . .	" . .	14	10 to 15 " . .	5 weeks . .	During first few weeks, but few new pustules. Absorption of nodules.
9	A. B., 31, M .	Acute eczema of the face.	" "	3	30 " . .	4 days. . .	Lessening of edema, decrease of burning sensation and appearance of scaling.

Minin reports favorable results in the treatment of painful bruises, hematomata, infiltrations, acute and chronic eczema, ulcers and burns. A large percentage were cured, in others he noticed great improvement. In addition, cases are cited where local anesthesia to the parts treated was produced, and later he used this as a method of local anesthesia, so that minor operations were made painless. Marcus has not been able to report such wonderful results as Minin, but nevertheless has found satisfaction with the method in numerous instances. On account of these reports the blue light treatment was instituted by myself in a number of cases which had been treated for an excessively long time with the x-ray, without any appreciable change, especially after the first few months of treatment. The changes after the first treatments were so marked that I can not fail to mention them here. These and other cases which I have treated in this manner will again be reported at a later date. On account of the limited work which has been done by myself in this field, I wish to be pardoned for presenting the same, but on account of the excellent improvement that I have seen in the cases treated, I have thought it advisable to bring this subject to the attention of those that are inclined to look into the subject, as I am made to believe that it may be of true value in a limited number of cases. The kind and details of the cases that I have treated can be seen from the following table.

A few words in regard to the possibilities. Holzknecht maintains that these rays can have no penetrating and curative power, unless when involving or destroying the uppermost or outer part of the body, or its integument. It is a fact, however, that with the Finsen method deep-seated tubercular nodules are favorably influenced, without involving the superficial strata.

Whenever taking up new methods there must be some ground for the same. The violet and ultraviolet rays were known to be anti-bacterial in action, but it was thought that the rays scarcely penetrated the epidermis. As authorities differ on this point it will be best to state that in all probability the blue and ultraviolet rays are absorbed in the true derma. If this is true, and I am inclined to believe that it is, the penetration of the rays can account, by the action on the tissue, for the results attained.

To sum up blue light therapy it is necessary to consider:

1. Simplicity in the mode of application.
2. Large or small surfaces may be treated.
3. No untoward effects, especially no deep-seated burns, as in case of x-ray therapy
4. Results, comparing with other forms of light treatment.
5. Expense of apparatus.

Reading in Bed.—Almost every English medical journal has had its say on the subject of reading in bed, and the discussion has been mentioned in a few journals on this side of the water. The consensus of opinion is as follows: Under proper restrictions one may indulge in reading in bed without harm, the position of the reader should be upright, or nearly so, the subject matter should be not too exciting or absorbing, the light should be bright and properly placed, and every one who indulges in the habit should use moderation.

STRANGULATED FEMORAL HERNIA CONTAINING APPENDIX.

REPORT OF TWO CASES.*

J. HENRY BARBAT, Ph.G., M.D.
Instructor in Surgery, Medical Department University of California.
SAN FRANCISCO.

Strangulated femoral hernia with the appendix alone as the contents is of sufficient rarity to report. In the literature I find reports of about 100 cases in which the appendix was found in femoral herniæ, but in only a few of these was the appendix the sole occupant of the hernial sac, and in only one or two has a primary strangulation of the appendix occurred. In most cases the appendix was found as a passive occupant of the sac, sometimes accompanying the cecum in its descent, and at other times projecting through the ring with a separate loop of bowel or piece of omentum. In order that the appendix may pass through the hernial ring it must be free in the abdominal cavity and possess a meso-appendix sufficiently long and lax to allow its descent. No case has been reported in which the appendix was found in a left femoral hernia.

Case 1.—My first case was Mrs. D., aged 66 years, who had been in good health for many years with the exception of a lump in the right groin which had been noticed for nine years, but which had given no particular trouble. Though occasionally it was tender on pressure, there never was enough discomfort to necessitate the services of a physician until the present attack. The patient was first seen by Dr. William N. Sullivan, who found that she had been suffering for three days from pain and tenderness over the mass in the groin. There was no vomiting or hiccough; pulse 85, temperature 100 F. I saw the case the next day in consultation, and found an inflammatory mass about two inches in diameter exceedingly tender to the touch situated directly over the right saphenous opening.

I made a diagnosis of either infected inguinal glands or a strangulated omental femoral hernia. The patient was removed to the hospital and operated on immediately. When the sac was opened about half an ounce of bad-smelling serosanguineous pus ran out. The contents of the sac consisted of the appendix, which was large, inflamed, and had a large perforation near the tip; an appendolith, which was lying in a small circumscribed abscess, and the meso-appendix, which was much hypertrophied from its long stay outside of the abdominal cavity. The whole mass was separated from the sac wall to which it was firmly adherent up to the ring, where it was found that the adhesions were so firm that it was not safe to attempt to liberate them, so the appendix and its mesentery were ligated *en masse*, removed, and the stump touched with pure carbolic acid. The cavity was drained with gauze. It closed rapidly, and the patient went home in three weeks. In this case no attempt was made to close the hernial opening because the stump formed an impassable barrier to any future hernia, and any such attempt would have been followed by failure on account of the infection. The appendix must have descended at the beginning of the trouble and during its long incumbency became firmly adherent to the femoral canal. Whether the concretion had started previous to the hernia or not can not be stated, but from its size and consistency it had certainly increased materially during the past few years.

The strangulation in this, as in most similar cases, was secondary and due to the swelling which followed the inflammation of the appendix; and from the condition of the structures in the femoral canal it would take very little swelling of the appendix to cut off the circulation and produce necrosis.

Case 2.—Mrs. C., aged 69 years, had had good health previously with the exception of backache, which was worse when she was sitting than when standing or walking. She had never noticed any disturbance in the groin at any time. She woke up one morning feeling perfectly well, and prepared the breakfast. During the meal she was seized with cramps and a bearing-down pain in the lower abdomen, more on the right side. She went to bed immediately and discovered a small lump in the right groin. She called her husband's attention to it, and he, having a rupture himself, thought that his wife's condition was similar to his own, and tried to reduce the mass by rubbing, but without success. Hot bags and other local applications were also tried.

I saw the case at 7 p. m., just twelve hours after the onset, and found the patient suffering intense spasmodic pain in the right groin, radiating up to the abdomen and back. The pain in the back caused more distress than the others. I mention this particularly because I believe that the backache which she had previously was due to the dragging on the meso-appendix during the formation of the hernia, which I think existed some time before its discovery, but which had never been apparent on account of the thick layer of fat. The patient had vomited once shortly after the beginning of the attack. The temperature was 101 F. and the pulse 100.

Examination disclosed a small mass about one and one-half inches in diameter just below Poupart's ligament, and directly over the saphenous opening, which was very tender and hard. I made a diagnosis of strangulated femoral hernia, and had the patient removed to the hospital at once for operation. When the sac was opened about two drams of odorless bloody serum ran out. It was seen at a glance that the contents of the sac consisted of the appendix doubled on itself and strangulated at the external ring. The tip was above the constriction and could not be pulled down until the ring was cut through, when the whole appendix could be pulled down with ease.

An interesting feature here presented itself: it was found that the tip of the appendix was almost gangrenous, while the rest was only intensely injected, showing that the double constriction had caused an earlier strangulation than the single constriction near the base. By carefully pulling on the appendix the cecum was drawn through the ring, the appendix removed in the usual manner, and the stump inverted according to Dawbarn. The femoral canal was closed by passing a few chromicized catgut sutures from the pectineal fascia to the under surface of Poupart's ligament, and the external wound closed in tiers. Recovery was perfect.

590 Sutter Street.

Clinical Report.

A CASE OF UNDESCENDED TESTICLE.

FRANK EUGENE PILCHER, M.D.
DETROIT.

The scarcity of literature on the subject of undescended testicles leads me to believe that possibly many cases are overlooked. The article of Dr. Bevan[1] on this subject is not only timely but very interesting and instructive, as it shows very clearly the technic of this operation, which in most cases is so important for the full development of the male child.

I agree perfectly with Dr. Bevan that the rule should be to operate and transplant to its normal position in the scrotum every undescended testicle which can be palpated. I also believe that every case of undescended testicle at the age of puberty should be operated on. The operation should be done as early as possible, and in every case before the age of 19. In several cases I have made the operation much as Dr. Bevan suggests, and in each case have had most satisfactory results. They were, however, with the single exception given below, under the age of 17.

History.—Walter W. aged 28, unmarried, called on me Feb. 15, 1902, complaining of a nervous condition which was rapidly growing worse, and seemed almost beyond endurance. For some time he had been under the care of different physicians of good standing, and for the past three years had been given almost constant treatment for stomach trouble, all to no purpose. During his first visit the following information was obtained. He was of an extremely nervous and excitable temperament, and had been so from his earliest recollections; decidedly feminine in his actions, choosing rather to do fancy work, housework or sewing to the more laborious occupations of his companions. The nervous condition had increased with years, and since the age of 18 had grown worse more rapidly. Spells of a mild form of melancholia were of frequent occurrence, but the one particular source of trouble was the stomach; he was very "fussy" about his diet, and quite as unreliable. It frequently happened that food prepared according to his directions would be refused when brought before him, a sudden nausea coming over the patient, making it impossible for food of any kind to be taken. Often after partaking of a well-cooked and properly served meal he would leave the table suffering a severe headache, and soon after be taken with vomiting, expelling the contents of the stomach in an undigested condition. Another symptom which was always present, differing only in severity, was pain of a sharp, shooting character through the abdomen, causing much suffering, and at times compelling him to remain away from work, frequently making it necessary to remain in bed for a few days. His nights were almost sleepless. What little sleep he had was disturbed by nervous twitchings, bad dreams, sudden starts or jumps, moanings, often shouting and delirium.

---

* Read at the September meeting of the California Academy of Medicine.

[1] The Journal A. M. A., Sept. 19, 1903.

Feb. 20, 1902, I was summoned hastily, being told that Walter was having a high fever and bad nervous spells, which had lasted for two days. Arriving at his rooms, the following condition presented itself: He was in a delirium of a somewhat violent type, did not recognize me and seemed unable to recognize his attendants or intimate friends. Medicines were positively refused, food likewise. Vomiting at first of undigested food, later of mucus, frequently occurred. It was impossible to keep him quiet, he would jump, toss and roll about the bed manifesting every symptom of severe pain. At times he would, in spite of restraint, jump out of bed shouting and crying as though persecuted by evil spirits. I was told that this was no uncommon condition (only perhaps worse) as it often followed an extra exertion, over-fatigue or undue excitement.

I called the following morning and found him much improved, although suffering in the same way at less frequent intervals. During his sane moments he could remember nothing of what had taken place during the delirium. In the afternoon of the second day, vomiting occurred, and improvement gradually followed. On the fourth day, all unfavorable symptoms subsided and he seemed to be as well as before the attack.

Shortly after this he left the city and I did not see him again until the following July, when he called at my office. All the symptoms above mentioned had grown worse, and some new ones had been added. Dizziness of a decided character was more or less constant, making him rather frightened to venture away from home. A temporary loss of mental faculties was probably at this time the most pronounced of the newer symptoms, for instance, he would leave some place for home, and perhaps, when he recovered consciousness would find himself some miles away from his destination, probably having gone in the opposite direction, and having not the least conception of when he got there. Music had at all times been the source of his greatest pleasure, and was the one thing of which he seemed never to tire, but now all was changed, he cared nothing for it, and usually it was very distasteful, often causing feelings of a depressing nature. Without warning and with no regard to surroundings he would break out into most hysterical and violent fits of crying, which seemed beyond his control. Instead of enjoying companionship as in the past, he dreaded meeting even his most intimate friends.

Diagnosis.—A satisfactory diagnosis had not yet been made by me. Further inquiry into the family and personal history revealed nothing of interest. I made very careful inquiry about the genitals, but could obtain no information that would in the least aid me. He had been circumcised a year before coming under my care. The time was now at hand either to give up as unable to cope with his complaint or to ascertain the cause and remove it. I demanded a thorough physical examination, telling him to remove all clothing, whereon strong objections were made, but as no objections would stand, and nothing short of the most rigid examination would satisfy me, he volunteered the information that he had no testicles and never had had any. At last here was the cause for which we had sought, and inspection failed to locate them. By palpation it was ascertained they were high up in the canal, the left one about three-fourths normal size, hard and painful, the right one more nearly natural size, very hard and extremely painful. Both were immovable. Palpation caused much suffering and a decided increase in all the nervous symptoms. I advised immediate operation.

Operation.—Sept. 2, 1902, the patient was admitted to the hospital, and on the following day the operation was performed. I had expected to follow the plan of procedure suggested by Dr. Bevan, but it was necessary to abandon this for the following reasons: When the sac was opened the testicle was found bound down by strong bands of adhesions, and only by the most patient work could the organ be freed enough to move it from its resting place. The cord could not be lengthened even by repeated efforts, and no better results were obtainable after some of the tense bands of connective tissue were severed. Careful dissection helped to free the testicle enough to lift it out of its bed. My original plan of bringing the organs down into the scrotum had to be abandoned and with some difficulty the ligatures were placed about the vaginal process and spermatic cord, each being treated separately. Then the organ was removed. The right testicle was treated in the same manner, as I found the conditions a counterpart of the left. The wounds were closed by buried catgut sutures and the skin incisions by interrupted silkwork sutures without drainage, the usual aseptic dressings being applied.

After the first 48 hours he suffered no pain, all nervous symptoms having disappeared. Gradually the appetite improved and soon he indulged in all varieties of food with no unpleasant results. On the tenth day the silkworm sutures were removed and three weeks after operation he left the hospital well. At the present time, one year after operation, he is in perfect health, having had no return of the mental or nervous symptoms, and has gained in weight and strength.

From my experience with this case it seems to me that possibly this cause is sometimes overlooked in the diagnosis and treatment of nervous troubles.

1300 Grand River Avenue.

Rabies vs. Diphtheria.—I. Prieto of Mexico mentions a case that occurred in the practice of G. Fabela in which a man was bitten by an animal supposed to be rabid. Four or five weeks afterward the man exhibited symptoms of hydrophobia, rapidly progressive. The physician diagnosed the case as hydrophobia, but ventured to inject antidiphtheria serum, knowing that it had sometimes displayed efficacy in diseases other than diphtheria. To his surprise the symptoms of hydrophobia promptly subsided and the patient recovered. Prieto himself had occasion to treat a case of hydrophobia two years ago, which had developed subsequent to a dog bite on the hand. The dog was a young, intelligent, great Dane, apparently in perfect health at the time and ever since. The case was diagnosed as nervous hydrophobia, with a favorable prognosis, but the patient rapidly succumbed with the typical picture of hydrophobia. In all his experience Prieto has never known a case of an animal's recovering from rabies. He compares this case with the one reported by Head and Wilson, in which the symptoms were those of hydrophobia, but the bacilli discovered were diphtheria germs. From all these facts Prieto deduces that the diphtheria bacillus is able to induce a symptom-complex in man exactly similar to that of hydrophobia, and it is more than probable that many cases of supposed hydrophobia were in reality this hydrophobic form of diphtheria. His article is published in the *Gaceta Medica*, the organ of the Academia Nacional de Medicina of Mexico, January 15, 1903.

THE CLINICAL STUDY OF DIABETES.

Last week[1] we emphasized the necessity for individualization in the directions to be given to diabetic patients, and urged that the method of treatment should be elected in accordance with the form of disturbance of sugar metabolism present. Our comments were founded mainly on the discussion[2] of the subject at the New Orleans session of the American Medical Association. In the symposium on diabetes at the recent meeting of the Medical Society of the State of New York,[3] this principle of the necessity for treating the individual affected with diabetes and not the diabetes itself, was emphasized by two such excellent therapeutists as Dr. William H. Thompson and Dr. Frederick C. Shattuck. In addition, however, some novel suggestions were advanced with regard to the necessity for more careful clinical differentiation of the varying forms, not alone as regards the "mildness" or "severity" of diabetes, but as to the particular type of failure to use carbohydrates which is present in each case. Dr. David Edsall[4] of Philadelphia, in a paper read on the "Physiologic Chemistry of Diabetes," called particular attention to the fact that it is not the power of using all starchy material which diabetic patients have lost, but that of properly elaborating—metabolizing, so to say—certain forms of starch which occur in an ordinary diet. No two patients are exactly alike in this regard, and the term diabetes, in its strict etymologic meaning, that unused material goes through the body and its limitation then to the tendency of sugar to *run through* the system without accomplishing its purpose, is unwarranted by the results of careful investigation.

Recent observations have shown that where the faculty to metabolize dextrose has been entirely lost, levulose (the form of sugar which turns the axis of a ray of light to the left) may still be ingested in certain cases in considerable quantities without any anomalous results. Some of the other isomeric forms of sugar may also prove innocuous for metabolism, even though dextrose can not be employed to any appreciable extent. At first, these observations were taken entirely as encouragements to look for unusual forms of sugary material that might possibly supply for the waste induced by the failure to use dextrose. Now, however, has come the thought that this should lead rather to further study of the special form of diabetes, or, in other words, the special form of failure to use sugary material from which an individual patient may be suffering.

It is not alone by delicate chemical differences that diabetic patients need to be separated into classes. Much cruder evidence of individual differences as regards starch, digestion and sugar metabolism may be found without the necessity either for detailed chemical knowledge or for refined laboratory methods. It is now known that some patients suffering from diabetes are able to use bread with much more impunity than others, while again some patients find that the starch obtained from potatoes is comparatively innoxious to them. Recently, von Noorden[5] has shown that a large number of diabetic patients can take oatmeal and be benefited by it, when other starchy products are sure to cause deterioration of their diabetes. It is probable that these individual differences, with regard to the power to use certain starchy materials, will be found to be much more complex than even this initial sketch would seem to indicate.

Dr. Edsall added that it is not impossible that there is a special ferment for each form of sugar, and that every kind of starch from every different vegetable is acted on differently before it is ready for use in metabolism. The old idea of starch digestion and absorption was simply that of conversion into sugar and then solution in the blood serum, from which it was absorbed in the muscles and liver for the various purposes for which it was needed. Physiology is, however, by no means the simple set of processes that it used to be considered. Dr. Edsall suggested that, as Ehrlich's theory of immunity demands the existence of many different kinds of receptors on the cells, a different one for each kind of infectious material that invades the body, so it may not be too much to look for a special kind of ferment for each of the various modes of starch, and that diabetes, like immunity, instead of being a simple process, is extremely complex.

In a word, the physiologic chemist has come back to the clinician for more data. Diabetes, far from being a simple form of disturbance of metabolism, is probably a very complex affection, with perhaps very different causes in different cases. The physiologic chemist has not solved the problem of diabetes, as it was so long hoped he would, but he has found that the clinical observer has not used the opportunities at hand for the differentiation of the affection into types of disease, some of which are much more easy of treatment than others. This return of the laboratory worker to the clinic is being noted along many lines in the study of nosology. Study at the bedside has been too much neglected of late years, and the result is apparently a serious setback for progress in medicine.

THE ETIOLOGY OF RHEUMATIC FEVER.

The recent work of Shaw[1] again calls attention to the problem of the microbic etiology of acute articular rheumatism or acute rheumatic fever. This has been a vexed problem for many reasons. As will have become apparent to the readers of The Journal in which this subject has been discussed many times, there have been various views held as to the cause, some proceeding from a purely *a priori* standpoint, others based on more or less imperfect evidence. The older view that a metabolic or autotoxic process was responsible has latterly been largely supplanted by the microbic intoxication or infection theory, having as its basis the analogies found in other infectious diseases and also certain bacteriologic findings. The views which have been held concerning the microbic cause are: 1, That it is a toxic disease caused by the absorption of bacterial toxins from a local point of infection (presumably the throat); 2, that it is microbic but not specific, more than one micro-organism being able to cause the disease (staphylococci and streptococci especially); 3, the now almost abandoned idea that the large anthrax-like bacillus of Achalme is the cause; 4, that a diplo-streptococcus is the cause; and 5, a specific micro-organism suspected, but its nature not known or proved.

Staphylococci have been recovered from cases of rheumatism by Guttman (1892), Sahli (1892), Singer (1894); staphylococci and streptococci by Singer; the bacillus of Achalme by Achalme (1891), Thiroloix (1897), and Triboulet and Coyon in two cases; streptococci, or a diplococcus considered to be a form of alteration of the streptococcus, by Netter (1892), Dana (1894), Charrin (1894), Buss (1894), Triboulet and Coyon in five cases, Apert and Triboulet in eleven cases, Westphal, Wasserman and Malkoff in one case, Poynton and Paine (1900) in eight cases, Beaton and Walker (1903) in fifteen cases. Menzer has also recently carried on extensive investigations in serum therapy with streptococci cultivated from the tonsils of rheumatic fever patients. It is thus seen that evidence has accumulated in favor of the streptococcus (diplococcus) etiology of the disease. Animal experimentation has also been encouraging with this organism as derived from a number of sources, particularly with inoculations into rabbits. Triboulet obtained changes in the endocardium, pericardium and joints similar to those found in man in rheumatic arthritis. Wasserman, in a remarkable series of eighty rabbits, obtained similar lesions with a streptococcus cultivated from a case of post-rheumatic chorea. The experiments of Poynton and Paine, Beaton and Walker, and finally of Shaw, have been confirmatory. In studying the reports of the disease as produced in rabbits, its close resemblance to the rheumatic fever of man, both in the essential lesions and in the so-called complications, is striking. The arthritis is wandering and non-purulent, and the valvulitis, endocarditis, pericarditis, myocarditis and pleuritis are said to be identical with the similar human lesions. One of Shaw's rabbits developed an acute iritis on two occasions. The micro-organism has been recultivated from all these foci, and in several instances the disease again produced by inoculation of the secondary cultures into other animals. Shaw performed two apparently successful inoculations on monkeys.

Confidence is transformed into confusion to a certain extent when one turns from these results to the report on 270 cases of acute articular rheumatism occurring in the Johns Hopkins Hospital,[2] where the cultural attempts were almost uniformly unsuccessful. It seems improbable that the disease could have one cause in England and another in America, but it is quite possible that differences in technic or culture media would explain the radically different results.

Although the results quoted above seem very promising, experience dictates that a certain amount of reserve is indicated in regard to them. The possibility of a secondary contaminating microbe occurring more or less constantly in a disease must always be kept in mind. The confusion caused by streptococci in the circulating blood in scarlet fever serves to emphasize this possibility. Then, again, while the reproduction of the disease in an animal experiment is of the utmost confirmatory value in establishing the microbic etiology of a disease, it can not be considered proof positive in all cases. We can never assume that the susceptibility of one animal will be equal in degree or character to that of another; the animal may not be susceptible at all, or the reaction may involve entirely different tissues. On the other hand, this test has at times been apparently successful, and still wrong conclusions drawn, as the results of animal experiments with various micro-organisms cultivated from syphilis testify.

While these criticisms may not hold eventually in regard to the diplococcus of rheumatic fever, the negative results among the Johns Hopkins cases make further confirmatory work necessary. It would seem that the optimum culture medium should be determined, likewise the optimum period of the disease for obtaining cultures.

ALBUMINURIA OF PUBERTY.

Albumin in small amount may appear inconstantly in the urine under so many varied circumstances that its discovery fails to arouse the concern that otherwise it would. Nevertheless, the underlying cause should, so far as possible, be sought out and corrected. The mere presence of albumin in the urine, without other evidence of disease of the kidneys or their adnexa, may be considered a functional disturbance indicative of renal insufficiency, which, in itself, may be attended with no injurious effects, but whose existence should raise a question as to the vulnerability of the organs concerned. In order, therefore, to avert more serious disorder, the urine should be examined with systematic regularity, both chemically and microscopically.

---

[1] Jour. of Path. and Bact., 1903, ix, 158.

[2] McCrae: The Journal A. M. A., 1903, xl, 211.

The qualification physiologic, as applied to albuminuria, does not seem entirely appropriate, as the fact of the condition being the exception rather than the rule indicates the contrary. There has also been described a form of albuminuria occurring at puberty and attributed to developmental conditions, as contradistinguished from the former, which has been attributed to constitutional conditions. In the course of observations made on 587 young men between the ages of 14 and 18 years employed as apprentices in the glass works at Jena, Dr. Felix Lommel[1] found albumin in the urine of 111. All were surrounded by favorable hygienic conditions. In some instances but a single examination was made; in others the examinations covered a period of from one to two years; while in the majority they covered a period of three or four years. Careful inquiry was made into the family and personal history.

In the overwhelming majority of cases the albuminuria was intermittent. Thus, in 90 cases in which the urine yielded a positive reaction, 436 examinations were made, albumin being found 164 times. Altogether, 2,220 examinations were made. The boiling test was employed at first, but later acetic acid and potassium ferrocyanid were the reagents used as being more delicate. The amount of albumin in the urine, as a rule, was exceedingly small; exceptionally it was considerable. Frequently it was from 0.5 to 1 per cent.; exceptionally more. Generally there was no sediment, or after prolonged centrifugation hyaline tube-casts and fatty degenerated epithelial cells were rarely found.

The albuminuria of puberty has been attributed in part to a depraved state of the blood, in part to a slight degree of cardiac insufficiency, with a tendency to stasis—abnormal conditions related to puberty and dependent on disparity between growth of structure and development of function at this time. Of 90 of the cases of albuminuria, the heart presented some abnormality in 38. In 13, enlargement of the heart to the left was found on percussion and palpation, associated with a heaving apex-beat, increased pulse-tension, systolic murmurs and accentuation of the aortic second sound. In 11 cases no enlargement of the heart was demonstrable physically, but the apex-beat exhibited increased resistance. In 9 cases a systolic murmur was audible; in the remainder there was persistent tachycardia and an increased area of cardiac dullness to the right. Similar conditions were found, however, in 29 cases unattended with albuminuria, so that the opinion is expressed that both the albuminuria and the cardiac disorder are manifestations of imperfect adaptation to the altered conditions of puberty. Violent physical activity was excluded as a possible cause of the albuminuria, which in many, however, may have been of orthostatic origin. Albuminuria was found only exceptionally in older employes under otherwise similar conditions.

A knowledge of the occurrence of functional albuminuria at the time of puberty may be of great importance in the differential diagnosis of chronic interstitial nephritis. Long-continued observation and a careful history are useful in this connection. Further, it should be borne in mind that in cases of albuminuria of puberty, the appearance of albumin in the urine is intermittent, and the amount of albumin rarely exceeds 1 per cent., while the presence of epithelial and granular tube-casts is indicative of the existence of nephritis. In doubtful cases, ophthalmoscopic examination may yield decisive information. An important lesson to be learned from the foregoing observations is that infallible significance should not be attached to hypertrophy of the left side of the heart and increased pulse-tension in the differential diagnosis of chronic interstitial nephritis.

THE STAND OF AN ORGANIZED PROFESSION IN GERMANY.

An interesting war has been in progress in Germany for many months. We have had much to say in our news columns concerning this conflict between the medical profession and the semi-official sick benefit and insurance societies (*Krankenkassen*). These workingmen's organizations are authorized and controlled to a certain extent by the government, and membership is compulsory. Recently, it appears, the law was changed doubling the length of time for which the members are entitled to medical treatment in case of sickness; and attempts have been made by the *Krankenkassen* to further reduce the compensation of the physicians, already ridiculously low. The result has been that the refusal of the physicians to serve under these conditions, which had been the result in one city, has extended to many other localities. The late numbers of our German exchanges contain standing advertisements warning physicians against taking positions in these *Krankenkassen*. In a few cases outsiders have assumed the work, but such have been few, and a recent development of the case is that the government itself has had to interfere. In the city of Cologne, for example, where the number of physicians obtained from the outside was very much less than the ratio established by law, the societies have been informed that they must immediately fill the quota. Being unable to do this, they have been obliged to discharge their outside employed physicians and take back the original ones on the terms demanded.

The German physicians have our fullest sympathy in their contest against the oppressive treatment by the workingmen's societies. The ideal for which they are striving in their dispute is the *Freie Arztwahl*, the privilege of free choice of physicians as opposed to the present contract system, and they compliment us by calling this the American plan. There is no sentimental element here that can be used in favor of the laboring classes. They act as do the most grasping and heartless monopolies and even outdo them in oppression. Human nature is much the same in all classes; if the workingman has the chance to oppress, he will take advantage of it to the fullest extent, as is seen in our own country. There is no reason why an honored and learned profession should be sweated in this outrageous way. The facts, as they come to us, are a warning for us to do all that we can to prevent the evil of club practice being introduced in this country.

---

[1] Deutsches Archiv für klinische Medicin, vol. lxxix, Nos. 5-6, p. 541.

Apropos to this subject, we may mention another peculiar situation which recently occurred in Germany, somewhat different from the one above mentioned. In Wiesbaden the physicians attending and acting in a local post-graduate course which was established by the government considered themselves grossly insulted by one of the medical government officials. The result was a most decided protest and a refusal to take part in the organization either as attendants or lecturers; and the offending official was ultimately obliged to make the best of his unfortunate position and resign. Experience will ultimately teach those whom it most concerns that our German confrères are altogether too gritty and are getting to be too well organized to be successfully ground between the lower and upper millstones of workingmen's *Krankenkassen* and arrogant officialism.

THE PROPOSED REORGANIZATION OF THE ARMY MEDICAL DEPARTMENT.

We publish elsewhere in THE JOURNAL[1] an account of the legislation now pending in Congress in regard to the Army Medical Department. It is well known to the profession that the status of the Army Medical Department, especially as regards the chances for promotion, is not at all satisfactory. The result is that there have been fewer applications for admission to the body and a larger number of resignations. To make the service more attractive and better able to meet the needs of the Army, a bill[1] has been introduced which provides for a reasonable number of physicians of the higher grades, thus removing the objections which exist in the present condition of affairs. Another important change of especial interest to the profession is that which provides for an army medical reserve corps. This will open a field for ambitious students, and give them at once a certain authorized medical status and the assurance of an army rank in case of war, provided they wish to accept it. This provision of the bill will be a popular one, and will have effects perhaps more beneficial and far-reaching than have been anticipated. The opportunity which is provided for instruction in the Army Medical School when there are vacancies, is itself a very desirable feature, which, we believe, will add to the attractions of the service, and the value of such a corps to the nation in case of emergency can not well be overestimated. We trust that our readers will use their influence to further this legislation so far as it is possible for them to do so. It is gratifying that the War Department takes the enlightened view of the subject that it does.

IN THE FIELD OF MEDICAL JOURNALISM.

With the new year a number of changes in medical journals are to be noted. Some have succumbed in the struggle to make ends meet, some have been merged into others, and in some communities new journals have come into being to aid the spread of medical science among the members of the profession. Among the latter are the *Los Angeles Medical Journal* and the *Medical Reporter*, the latter being from Shreveport, La. If one may judge by the first few numbers of these monthlies, they will be of value to the local profession, in the broad but practical scope of their contents. We have often referred to the shortsightedness of the practitioner who does not take, or who fails to read, at least one weekly scientific medical journal, national in character, that he may keep up with the current practice of his profession. At the same time, he should take his local publication and support it enthusiastically. Such a journal has a sphere of usefulness as a representative of the physicians and as the mouthpiece of the organized profession of the territory it covers. Where two or more journals draw for support from the same field, consolidation will avoid waste and make for a better journal. It may reduce the number of editors, but it will benefit the readers and the profession as a whole. There are a few exceptions where rivalry is a stimulus to excellence. The value of consolidation is recognized in the recent merging of the *Medical Dial* into the *Northwestern Lancet*, these two journals having for some time occupied the same field in Minnesota. Both of these journals have been very ably edited, and the *Lancet* should now be better than ever. The *Journal of the Kansas State Medical Society* has absorbed the *Wichita Medical Journal* and the *Western Medical Journal*. This leaves only one medical journal in Kansas, and though a small publication, it is an able and wide-awake representative of the profession of the state. Quality is preferable to quantity, and growth will follow. Among other changes we note the suspension of the *Journal of Tuberculosis*, and the consolidation of the *Archives of Pediatrics* and the *International Medical Magazine* under the name of the former.

SUPPRESSION OF A MEDICAL MEETING.

The antituberculosis crusade prevailing throughout the civilized world has had an unexpected effect in at least one quarter. According to correspondence in the London *Lancet*, a medical convention held last month in St. Petersburg was dispersed by the police. This sounds rather strange to us, but it seems to be the order of things in Russia. The medical men present, in their zeal for the suppression of the tuberculosis scourge, demanded freedom of speech and of instruction by newspapers and lectures, a demand which the Czar or the powers behind his throne considered subject for police interference. It is possible, the correspondent says, to give lectures on hygiene, ventilation, etc., in Russia, but any systematic attempt at this falls under the suspicion of the police, some political motive is suspected, and the scientific lecturer on sanitation may find himself banished to Siberia. The convention, however, did more than to ask for the education of the public. The evils of overcrowding, which are so obvious in relation to the subject of tuberculosis, were especially emphasized as occurring in the crowded ghettos of the Jews. There are some 5,000,000 Jews, it is estimated, in Russia, and those who inhabit the larger towns are compelled to live in special quarters, cut off from fresh air and country life. The artificial concentration of the Jews in the special quarters allowed them is an evil that the hygienists felt called on to notice. In the present state of the official mind it was only a provocation, the result of which is shown as above. We do not wish to prejudice anybody against the Russians or Russian administration at the present time, but it is very unfortunate that such an event as the suppression of a scientific congress for simply doing what every scientific physician must consider was its duty should have occurred. As the *Lancet* correspondent remarks, whenever practitioners of Russia assemble and touch on such subjects, they are accused of dabbling in politics, and it is fortunate if some of them are not arrested and imprisoned. "How medical science and sanitation can progress under such conditions is a question that the Russian government must be left to answer."

---

[1] See page 605 of this issue.

DECAYING FISH AND LEPROSY.

Dr Jonathan Hutchinson's theory that the eating of badly preserved fish is the chief, or, indeed, almost the sole cause of leprosy, recently has been revived in a number of the daily newspapers. For this reason it may be well to refer to some work that has been done in this connection. Professor Hansen of Norway, the discoverer of the bacillus of leprosy, tried for several years to find the lepra bacillus in tainted or fresh fish. He also tried to determine the possibility of such material being a source of leprosy in any way. His investigations were apparently without success. Except Dr. Hutchinson himself, there is no authority on leprosy, so far as we know, who advocates the theory. Dr. Isadore Dyer of New Orleans, who is our American expert on leprosy, having ample opportunity for the study of the disease among the lepers of Louisiana, has investigated the possibility of Dr. Hutchinson's theory being true, and continues to pronounce against it as he did during the lepra conference at Berlin in 1897. During last year a number of English and Anglo-Indian physicians, who have been studying leprosy in India, gave their opinions with regard to the dried-fish theory of the origin of leprosy. One of them brought forward the details of 102 cases of leprosy which had occurred in patients who had in India lived exclusively on rice, and who had never tasted fish. Dr. William Hynsey, who is very well known as a conservative observer and distinguished medical authority in India, declares that though dried fish is used universally all over the island of Ceylon, leprosy is confined to a few scattered villages along the coast. If fish in a poor state of preservation were the cause of leprosy, then the disease should be much more common in the interior, the fish becoming tainted during carriage inland, owing to primitive methods of curing. It is just there, however, that leprosy does not exist at all. Dr. Hutchinson's theory has been before the public now for many years. Ever since the discovery of the bacillus of leprosy, observers in many parts of the world have been striving to find the bacillus in fish. Almost needless to say, it would be one of the landmark discoveries of all time if it should be found there, and would mean enduring fame for the discoverer. Notwithstanding the stimulus to investigation that such considerations afford, no sign of the bacillus of leprosy, either in fresh or tainted fish, has ever been discovered. Dr. Hutchinson confesses that such a discovery must eventually be the crucial test of his theory, and he looks forward with confidence to the time when the micro-organism shall be found as a parasite of spoiling fish. He has been thus expectantly looking forward, however, for over a decade of years now, and not the slightest confirmation of his theory has come. The whole discussion in the newspapers is a bit of that popular science that unfortunately sometimes attracts attention to subjects that deserve not to be mentioned at all. The abuse of the fish diet, however, as regards the use of decaying fish, is not a matter we are now discussing. Its causation of temporary disorders is evident, and it may easily be a predisposing factor in many serious diseases.

Medical News.

(The Journal goes to press Wednesday morning.)

ILLINOIS.

Hospital Day in Evanston.—February 14 was "Hospital Day" in Evanston churches, and about $6,500 was subscribed for the support of the Evanston Hospital for the current year.

Improved Medical Service.—The medical staff of Cook County Institutions, Dunning, has been increased by five. The consulting staff will be composed of one specialist each in internal medicine, tuberculosis, insanity, pathology and surgery.

Society Donates Library.—The Peoria Medical Society has offered its library of about 1,000 volumes to the Peoria Public Library on the condition that they be placed in a separate room and constitute a medical department of the library.

Personal.—Dr. and Mrs. Frederick W. Werner, Joliet, start to-day for a tour of Mexico and California. They will return in about a month.——Dr. Nicholas Senn, Chicago, has been made a corresponding member of the Surgical Society of Paris.——Dr. and Mrs. John B. Murphy, Chicago, have gone to California.

Chicago.

Perilous Economy.—The finance committee of the city council has denied the requests of the health commissioner for increases of $15,000 for vaccination expenses; $10,000 for antitoxin; $32,000 for more sanitary inspectors, and $2,500 for more tenement-house inspectors.

Pneumonia and Consumption.—There were 170 deaths reported from pneumonia during the week ended February 20—a little more than one-fourth (26.1 per cent.) of the total 651 deaths from all causes. Since the first of the month there have been 496 pneumonia and 195 consumption deaths reported, and since the beginning of the pneumonia season, Nov. 1, 1903, there have been 1,831 pneumonia and 863 consumption deaths reported. Out of the total of 8,757 deaths from all causes reported during the period consumption caused 9.8 per cent. and pneumonia 20.9 per cent.

MARYLAND.

No Commemoration Exercises.—The Johns Hopkins University, Baltimore, omitted celebration of Commemoration Day this year owing to the fire. For twenty-seven years it has celebrated February 22 with public exercises and an address.

The Baltimore Fire Losses.—It is now known that sixty-eight warehouses, widely scattered, belonging to the Johns Hopkins Hospital, Baltimore, were destroyed in the fire. The general office of the hospital on Holliday Street having been destroyed, it is impossible to estimate how much insurance may be recovered. It is said that the income from the burned buildings was devoted to the free work of the hospital, which will suffer along with the clinical facilities. The origin of the fire is still a mystery; the owners and occupants of the Hurst store where it began deny most positively that there was any gasoline in it. The loss of life still remains one. As we go to press a report, as yet unconfirmed, has reached Baltimore that John D. Rockefeller has given $1,500,000 to the Johns Hopkins Hospital to enable the institution to tide over its losses in the fire and to avoid abandonment of its free dispensary work.

MASSACHUSETTS.

Nurses Urge Registration.—The nurses of the state are very earnestly urging the passage of a law to permit their registration similar to the laws already enacted in New York, New Jersey, North Carolina and Virginia.

Personal.—Drs. C. M. Hutchinson, Myron L. King and Arthur Moll are the newly-elected members of the board of medical inspectors for the public schools of Cambridge.——Dr. Fritz Walter Gay has been appointed pathologist to the Malden City Hospital.

Physician Robbed.—On February 3 Dr. William A. Hale, Boston, was lured to a hallway by some colored men on the pretense of a sick friend, beaten and robbed of $200. His assailant has been caught and identified and is held under $2,000 bonds for trial.

Gifts Present and to Come.—By the will of Miss Mary Sophia Walker of Waltham, $5,000 is left to the Waltham Hospital, and to the Boston Lying-in Hospital, Children's Hospital and the Wellesley Convalescent Home $1,000 each. The bulk of the estate, between one and two millions of dollars, is left for the erection of an Episcopal Cathedral, and in the event of the church failing to carry out her requests, the Massachusetts General Hospital is to receive $50,000.

Disease and Death.—During the four weeks ended February 20 there were reported to the board of health in Boston 848 deaths, a decrease of 112 from the same period last year, equivalent to an annual mortality of 18.82 per 1,000. There were 178 cases of diphtheria, with 14 deaths; 130 of scarlet fever, with 5 deaths; 27 of typhoid fever, with 5 deaths; 740 of measles, with 10 deaths, and 152 of tuberculosis, with 100 deaths. Pneumonia was the cause of death in 143 cases; whooping cough in 3, heart disease in 92, bronchitis in 30, and marasmus in 13. The general improvement in health over similar periods in former years, and especially the low number of deaths from pneumonia, 40, 29, 32 and 42 for the weeks noted respectively, may be attributed to the constant covering of the streets with snow, and the success of the street railway company in keeping its surface and elevated cars well heated.

MICHIGAN.

Smallpox.—At the Pittsburg mine, near Bay City, eight cases have been reported.——Mendon has six cases.

Pneumonia Reportable.—Beginning Jan. 1, 1904, health officers have been required to make reports of pneumonia in the same manner as consumption, diphtheria, typhoid fever, scarlet fever, measles, whooping cough, meningitis and smallpox are reported.

Griswold Pardoned.—Dr. Roy W. Griswold, Bay City, sentenced a year ago to two years' imprisonment for causing the death of a woman by a criminal operation, has been pardoned, on the affidavit of the chief of police of Bay City that the operation for which Dr. Griswold was tried and sentenced was performed in Detroit. The prosecuting attorney also favored the pardon.

Prevalence of Disease.—For the month of January, compared with the preceding month, influenza, diarrhea, measles, smallpox and remittent fever were more prevalent, and typhoid fever, whooping cough and meningitis were less prevalent. For the month of January, compared with the average for January in the ten years, 1894-1903, typhoid fever, measles, diphtheria and smallpox were more than usually prevalent, and pneumonia, intermittent fever, erysipelas, inflammation of bowels, remittent fever, dysentery, whooping cough and meningitis were less than usually prevalent.

Communicable Diseases.—Including reports by regular observers and others, meningitis was reported present in Michigan during January, 1904, at 8 places, whooping cough at 22 places, typhoid fever at 93 places, pneumonia at 98 places, diphtheria at 101 places, measles at 102 places, smallpox at 122 places, scarlet fever at 195 places, and consumption at 195 places. Reports from all sources show meningitis reported present at 1 place less; whooping cough at 3 places more; typhoid fever at 24 places less; diphtheria at 1 place more; measles at 40 places more; smallpox at 32 places more; scarlet fever at 23 places more; and consumption at 6 places less, in January, 1904, when compared with the preceding month.

Mortality During January.—There were 3,126 deaths reported for January, corresponding to a death rate of 14.7 per 1,000 population. The number was 184 larger than that registered for the preceding month, and is also greater than the number for January, 1903. By age there were 490 deaths of infants under 1 year of age, 210 deaths of children aged 1 to 4 years, and 982 deaths of elderly persons over 65 years of age. The age distribution was practically the same as for the preceding month. Important causes of death were as follows: Pulmonary tuberculosis, 176; other forms of tuberculosis, 25; typhoid fever, 57; diphtheria and croup, 83; scarlet fever, 34; measles, 12; whooping cough, 19; pneumonia, 412; influenza, 101; cancer, 134; accidents and violence, 180.

MISSISSIPPI.

Smallpox in Yazoo City.—Five cases of smallpox are reported in Yazoo City. Quarantine has been established.

Prosecute Illegal Practitioners.—Dr. Hyman M. Folkes, Biloxi, member of the State Board of Health, has employed an attorney to prosecute all violators of the medical practice act in the Sixth District. Under th[illegible] Doty has convicted Dr. John M. Smith of [illegible] practice. It seems that Dr. Smith, while a resident of Louisiana, had secured a non-resident license from the Mississippi State Board to practice in counties contiguous to the Louisiana parish, of which he was a resident. On this license he undertook to practice in the state of Mississippi, moving from his Louisiana home to Poplarville, Miss., where he has been practicing for the past five years on this license. He appealed the case, but precedent shows that he has no chance of winning his contention in this state.

State Board of Health Named and Confirmed.—The governor has appointed the following as a state board of health for a term of four years: Drs. Walton S. Green, Aberdeen; W. H. Harrison, Tutwiler; Jefferson D. Smythe, Greenville; Benjamin F. Ward, Winona; G. H. McNeil, Newton; Jefferson D. Donald, Hattiesburg; Ernest P. Jones, Hermanville, and John H. Rhodes, Jackson. He also confirmed the following nominations for the state at large made by the Mississippi State Medical Association: Drs. J. Augustus Crisler, Yazoo City; William M. Paine, Aberdeen; John R. Tackett, Meridian; Peter W. Rowland, Oxford, and John F. Hunter, Jackson.——At the meeting of the board for organization at Jackson, February 16, the following officers were elected: President, Dr. Benjamin F. Ward; secretary and chairman of the executive committee, Dr. John F. Hunter, and executive committee, Drs. Walton S. Greene and John R. Tackett.

MISSOURI.

Physician Against Physician.—In the suit of Dr. M. Pinckney Morrell, St. Louis, against Dr. Joseph J. Lawrence of the same city for $16,000 for services rendered the son of the latter, the jury gave a verdict of $12,666 for the plaintiff.

Smallpox Rages.—An epidemic of smallpox is said to have been raging in Greenbrier and vicinity since June, 1903. In all about 150 cases have occurred, and the type of the disease is progressively becoming more severe. Three deaths have occurred thus far.

Anti-Spitting Ordinance Recommended.—Butler County Medical Society, at its January meeting, unanimously endorsed resolutions recommending the enactment and enforcement of an ordinance making it a punishable offence for anyone to expectorate on the sidewalks of Poplar Bluff.

Will Reorganize Medical Department.—Major Daniel Morton, surgeon, N. G., M., has been appointed acting chief surgeon of the National Guard of the state. His first duty will be the reorganization of the medical department and hospital corps of the state to accord with the provisions of the Dick bill.

Pneumonia Leads.—During January 272 deaths occurred from pneumonia, in St. Louis; in January, 1903, only 118 deaths from this cause were reported. The deaths for the week ended February 6 numbered 219, of which 42 were due to pneumonia, and 19 to consumption. For the week ended February 20, pneumonia still leads with 36 out of 214 deaths, consumption following with 26 deaths.

Personal.—Dr. Robert H. Goodier, Hannibal, has been appointed a member of the State Board of Health, vice Dr. Benjamin G. Dysart, deceased.——Dr. Jacob S. Triplett, Harrisonville, has been appointed secretary of the Cass County Board of Health.——Dr. Henry S. Atkins has succeeded the late Dr. Edward C. Runge as superintendent of the St. Louis Insane Asylum.——Dr. Jules M. Brady has returned to St. Louis after a year in Vienna.——Dr. John H. Simon, health commissioner of St. Louis, is seriously ill with pneumonia.

NEBRASKA.

Smallpox at State University.—Smallpox has appeared in Lincoln, and has caused the closure of one of the fraternity houses.

Hospital Fair a Success.—The fair recently held in Kearney for the benefit of the new hospital yielded net proceeds exceeding $2,000.

Omaha's Health.—During 1903 Omaha had no epidemic of any kind. The deaths numbered 967, a mortality rate of 9.38 per 1,000.

Physician Wins Suit.—Dr. Joseph H. Thompson, Albion, secured a verdict in his favor in the damage suit for $5,000, brought against him by James Brown for alleged malpractice.

Personal.—Dr. George E. Spear, Lincoln, has the honor of being the first resident physician of St. Elizabeth's Hospital in that city.——Dr. Owen B. Canfield, Edgar, is seriously ill with spinal disease.

Must Report and Pay Postage.—The attorney general has handed down the opinion that physicians must report to the State Board of Health all cases of contagious disease, including smallpox, cholera and yellow fever, and further, that they must pay postage on such reports.

Saunders County Medical Society.—At the annual meeting held in Wahoo, Dr. Alexander S. Von Mansfelde declined reelection as president. Dr. Joseph P. Percival, Prague, was then elected president; Dr. Frank Fornholm, Wahoo, vice-president; Dr. Mary A. Quincy, Ashland, was re-elected secretary, and Dr. John G. Smith, Wahoo, treasurer, and Dr. William J. Pinkerton, Mead, censor. The organization was organized in January, 1903, with a membership of 10; since then eight have joined, so that at present 18 out of 26 practitioners in the county are members.

NEW YORK.

Personal.—Dr. William E. Ard, for several years surgeon to the Binghamton City Hospital, has removed to New York City and entered into partnership with Dr. J. Gorse Simmons.——Dr. James E. Kelsey, Theresa, has gone to Cuba.

Practical Tests for Candidates.—The five candidates for the position of superintendent of the new state hospital for tuberculosis were each required to examine five patients, tuberculous or pseudo-tuberculous, and discover and report the physical condition of each.

Buffalo.

Children's Hospital.—The eleventh annual report of the Children's Hospital shows that the average daily number of patients has been almost double that of former years. The incubators in use have been so successful that it has been necessary to add four to the original two, and they have been in almost constant use.

January Deaths.—The report of the department of health for January shows an annual death rate of 14.43 per 1,000. The principal causes of death were as follows: Consumption, 46; cerebrospinal meningitis, 3; diphtheria, 10; typhoid fever, 13; debility, 31; cancer, 21; apoplexy, 19; cerebral tumor, 4; meningitis, 20; valvular disease of the heart, 29; bronchitis, 16; pleurisy, 1; pneumonia, 54; appendicitis, 3; nephritis, 24, and violence, 25. The total deaths for January were 457, as compared to 441 deaths in January, 1903.

New York City.

Concert for Hebrew Charities.—A concert was given in the Montauk Theater, Brooklyn, January 31, for the benefit of three Brooklyn Jewish charities. More than $10,000 was realized, of which one-third will be given to the Hebrew Hospital.

Honor Re-elected President.—The Society of German Physicians of Brooklyn at its annual banquet did especial honor to Dr. John H. Droge, president and president-elect of the society, under whose administration the membership of the club has materially increased.

Bellevue Authorities Exonerated.—Coroner Jackson, after hearing the evidence, directed the jury to exonerate the Bellevue Hospital authorities from the charge of brutality in the case of Adolphus Drucker, the English member of parliament who died in the alcoholic ward of the hospital in December last.

Must Not Use Saliva on Transfers.—The board of health of New York City has issued a mandate forbidding street-car conductors to moisten their fingers with saliva in order to separate the transfers before dealing them out to passengers. Fears of disseminating disease germs caused this action of the board.

Conrad Escapes.—Dr. Edward E. Conrad, who was arrested, February 12, at the instance of the New York County Medical Society, on the charge of attempting to perform an illegal operation, has been released. The grand jury, on February 17, dismissed the complaints against him, and against the nurse arrested with him.

Surgical Kits for Fire Trucks.—The first installment of 25 leather cases has been delivered to the hook and ladder companies of the city. The cases were designed by Dr. E. Benjamin Ramsdell, chief surgeon of the fire department, are of heavy black leather, twenty-two inches long, and contain sterilized gauze and cotton, iodoform, emergency medicines, forceps, scissors, tourniquets, trays for disinfectants, needles and splints, and other necessary articles. They will be strapped under the seat of each truck.

To Relieve Non-Pulmonary Tuberculous Children.—At the last meeting of the Association for Improving the Condition of the Poor, $15,000 was appropriated for the maintenance at the seaside of 50 children suffering from non-pulmonary forms of tuberculosis. According to Dr. Biggs of the health department, there are in the New York tenements alone from 3,000 to 4,000 children under 15 years of age suffering from tuberculosis of the bones, joints and lymph glands. Tuberculosis of the lungs affects but a relatively small number of children under 15.

OHIO.

National Guard Medical Examining Board.—The adjutant general has announced the appointment of Major Lovett T. Guerin, Captain Sterling B. Taylor and Captain Cassius M. Shepard, all of Columbus, as a board to examine individuals recommended for commission in the medical department of the National Guard.

Cleveland Water Is Bad.—Dr. Howard, city bacteriologist, who has made tests of the water from the new tunnel, just completed, reports it infected with typhoid bacilli. The tunnel cost in all in the neighborhood of $10,000,000, and extends five miles into Lake Erie. There is said to be over 500 cases of typhoid in Cleveland at present.

Medico-Military Appointments.—Dr. Frank W. Hendley, formerly superintendent of the Cincinnati Hospital, has been appointed major and surgeon, and assigned to the First Infantry.——Dr. Charles Cullen, Cincinnati, has been appointed first lieutenant and assistant surgeon and assigned to the same regiment.——Dr. Franklin B. Entrikin, Findlay, has been commissioned major and surgeon and assigned to the Second Infantry.

Society Elections.—Logan County Medical Society.—At the annual meeting in December, the following officers were elected: President, Dr. Lester C. Pratt; vice-president, Dr. John S. Deemy; secretary, Dr. Simon Morgenroth; treasurer, Dr. Perry D. Covington, and censors, Drs. Abraham L. Huston, John S. Deemy, and Lester C. Pratt, all of Bellefontaine.

Academy of Medicine of Cleveland.—At the second annual meeting held December 18, the following officers were elected: Dr. George W. Crile, president; Dr. William E. Bruner, vice-president; Dr. Edward Lauder, secretary; Dr. Oscar T. Thomas, treasurer, and Drs. William O. Osborn and Hunter Robb, trustees.

GENERAL.

Home for Blind Lepers.—At the leper settlement in Molokai, Hawaii, there has just been completed a home for blind leper women, the gift of Charles R. Bishop.

Missouri Valley Medical Society.—The spring meeting of this association is to be held in Lincoln, Neb., March 24 and 25. The program announces some excellent papers and practical subjects, and that several clinics are to be held by local physicians.

Smallpox on Battleship "Maine."—The United States battleship *Maine*, on her arrival at Guantanamo, Cuba, February 18, was quarantined because of a number of cases of measles and one case of smallpox on board. The latter has been taken to the hospital on the quay. The auxiliary cruiser *Yankee* had one case of measles on board, which was isolated on a lighter in the bay.

Special Pullmans for Consumptives.—As the result of agitation on this subject, and especially following the recommendations of the United States Public Health and Marine-Hospital Service, it is announced that the Pullman Company will add to its equipment hospital cars to run to California on certain days each week, in which consumptives and other sick persons must travel, ordinary Pullmans being reserved for persons in health.

Yellow Fever Investigation.—The delegation of health officers of Louisiana, Mississippi and Alabama was cordially welcomed in Mexico and had a very successful tour. The officers report unofficially that the sanitary measures (drainage, etc.) which they would recommend in some Mexican cities may be more expensive than the municipalities can afford. One recommendation is a system of inspection by health officials. Their full report will be issued later.

Leprosy Committee.—The committee on leprosy of the Second Annual Conference of State and Territorial Health Officers with the United States Public Health and Marine-Hospital Service has been announced as follows: Dr. Charles B. Cooper, president of the Territorial Board of Health, Honolulu, chairman; Dr. J. F. Smith, secretary of the Superior Board of Health, San Juan, Porto Rico, and Dr. J. C. Nolte, secretary of the Louisiana State Board of Health.

Physicians to Visit Rome.—A number of the physicians of Paris, who are united under the patronage of Saints Luke, Cosmas and Damien, three saints who were also medical men in the olden times, have decided to make a pilgrimage to Rome, April 5-14, 1904, and extend an invitation to physicians throughout the world to accompany them. First class the price is to be about $70; second class, less than $60; and third class less than $50 for the round trip from Paris to Rome and back, including all railroad expenses, hotel expenses at Rome for six days, for carriages, interpreters, guides, fees for museums, tips, etc. Pope Piux X, it has been arranged, will receive the physicians in private audience and will grant them the privilege of a visit to the gardens of the Vatican, which is never allowed to ordinary visitors. The families of physicians are admitted to all the privileges physicians will receive. Application must be made before the end of February and the price of the trip paid before March 10 to M. le Docteur H. Dauchez, secretary general of the Society of St. Luke, 5 rue Bayard, Paris, France.

Examination for Marine-Hospital Surgeons.—The surgeon general of the U. S. Public Health and Marine-Hospital Service announces that there will be an examination at the bureau, 3 B Street, S. E., Washington, D. C., Monday, April 4, 1904, at 10 a. m., of candidates for assistant surgeonships. The candidate must be between 22 and 30 years of age, graduate of a reputable medical college, and must furnish testimonials from responsible persons as to his professional and moral character. In addition to the physical examination, candidates are required to certify that they believe themselves free from any ailment which would disqualify them for service in any climate. The examinations are chiefly in writing, and begin with a short autobiography of the candidate. The remainder of the written exercise consists in examination on the various branches of medicine, surgery and hygiene. The oral examination includes subjects of preliminary education, history, literature, and natural sciences. The clinical examination is conducted at a hospital, and when practicable, candidates are required to perform surgical operations on a cadaver. Successful candidates will be numbered according to their attainments on examination, and will be commissioned in the same order as vacancies occur. On appointment the young officers are, as a rule, first assigned to duty at one of the large marine hospitals, as at Boston, New York, New Orleans, Chicago or San Francisco. After five years' service, assistant surgeons are entitled to examination for promotion to the grade of passed assistant surgeon. Promotion to the grade of surgeon is made according to seniority, and after due examination, as vacancies occur in that grade. Assistant surgeons receive $1,600; passed assistant surgeons, $2,000, and surgeons, $2,500 a year. When quarters are not provided, commutation at the rate of $30, $40 and $50 a month, according to grade, is allowed. All grades above that of assistant surgeon receive longevity pay, 10 per cent. in addition to the regular salary for every five years' service up to 40 per cent. after twenty years' service. The tenure of office is permanent. Officers traveling under orders are allowed actual expenses. For further information, or for invitation to appear before the board of examiners, address the surgeon-general, as above.

CANADA.

Personal.—Dr. Claude W. Freeman has been appointed medical superintendent of the Hamilton City Hospital.

To Improve Marine Hospital at Victoria.—The government has appropriated $3,000 toward the Marine Hospital at Victoria, B. C., for much-needed improvements.

Toronto General Hospital.—This hospital has accommodation for 425 patients daily, but the usual average is between 250 and 300. During the year over 3,300 patients are treated in the wards, and about 16,000 in the outdoor departments. It has the largest number of beds of any hospital in Canada.

Generous Gift to Science.—Lord Strathcona has given $20,000 to Manitoba University for the extension of the science department. This timely gift will enable the university to commence development at once. When the sum given may be exhausted, the disposal of a large portion of lands held by the university will provide a yearly revenue fully adequate for all pressing university purposes.

Toronto University Hospital.—The authorities of the University of Toronto and the medical faculty thereof are considering the possibility of erecting a hospital for all classes of patients near the new medical building, to make better facilities for the medical students. If this is not carried out in the immediate future, it is altogether likely that a small building will be erected for outdoor clinics.

Montreal General Hospital Annual Meeting.—At the eighty-second annual meeting of the corporation and board of governors of the Montreal General Hospital, last week, the medical report showed that the total number of patients which passed through the wards in 1903 was 3,066, against 2,878 in 1902, or an increase of 188. The outdoor patients numbered in 1903 35,984, as against 31,993 in 1902, an increase of 3,991.

Sanitary Barber Shops.—A bill before the Ontario legislature seeks to prohibit and regulate the admission to barber shops of persons suffering from disease, to provide for the regular and efficient cleansing of shops and instruments, to secure the personal cleanliness of the barbers, and sanitary condition of the premises, and to prohibit the employment of any one as a barber while suffering from any infectious, contagious or communicable disease.

War Against Patent Medicines.—The Ontario council of the Royal Templars, at a recent session in Toronto, discussed the amount of alcohol in patent medicines, which, by expert analysis, is shown to be from 14 to 40 per cent. Since several of those with the higher percentages are purchased purely for the liquor in them, it was decided to ask for legislation prohibiting the sale of all such medicines which contain a greater percentage of alcohol than is necessary to preserve them.

Canada to Guard Against Diseased Immigrants.—We have mentioned the alarm of the Canadian government over the number of immigrants allowed to enter Canada each year suffering from trachoma and favus. Last year a small house was rented in Quebec as a temporary hospital in which as many as 220 immigrants suffering from these diseases were huddled at one time. It is proposed to erect a detention hospital in Quebec, to care for such persons until they can be sent out of the country.

Dental Changes in Quebec.—An important meeting of the Dental Association of the Province of Quebec was held last week in Montreal, which, after a rather stormy discussion, endorsed the action of the board of examiners in their recent negotiations with McGill and Laval universities. This means that the present Dental College of the Province of Quebec will be abolished, McGill furnishing the dental course for English-speaking and Laval for French-speaking students. McGill, however, declines to grant the degree of doctor of dental surgery until three years after graduation and then on condition of the applicant writing a technical thesis to be approved by the board. The degree they will grant on graduation is master of dental surgery. Laval will grant the D.D.S. on graduation. The term will be lengthened to nine months and the course of study will remain four years. McGill's course will be a department of the medical faculty.

FOREIGN.

Diphtheria Epidemic in Mexico.—Eleven deaths from diphtheria in one day are reported in Guadalajara, Mexico. The epidemic is severe.

Ziehen Called to Berlin.—The chair of psychiatry left vacant by the death of F. Jolly has been given to Ziehen of Halle, who enters on his duties April 1.

Sanatorium for Physicians in Russia.—A fund is being raised in Russia to construct a sanatorium in the Crimea for physicians needing a trip to a southern climate.

Fire in Scottish Hospital.—A fire, February 12, at Broomhill Home for Incurables, Kirkintilloch, Stirlingshire, Scotland, did damage to building and equipment, but caused no loss of life.

Edinburgh Schools Short of Dissecting Material.—Medical schools in Scotland are said to be short of bodies for dissection, owing to objection on the part of the poor-house officials to allow bodies to be used for dissection.

Arguments of Antivivisectionists.—Among the arguments recently presented by some antivivisectionists at Paris was one to the effect that vivisection is of no use to surgery as "the assumed analogy between the organisms of man and of animals is deceptive and misleading. The proof of this fact is furnished by the Americans. They do not practice vivisection and yet they lead the world in surgery."

Damages Claimed from French Alienists.—In 1901, at Paris, a Countess Clozewska fired a blank cartridge at the carriage in which a member of the French cabinet was passing. She was arrested, but was declared irresponsible by the alienists, Drs. Germain, Legras and Vallon, and taken to the Sainte-Anne Asylum. She has recently been set at liberty and has sued each of the experts for $20,000 damages for stating that she was irresponsible, with the consequent detention in the asylum.

The Russia-Japan War.—The Red Cross Society of Russia is taking hold vigorously of its work in the war. Over five million dollars has been subscribed for its purposes, and many trains loaded with supplies have been sent across the continent. M. Alexanderovsky will be in charge on the field. Hospitals on the Amur will be established, and detachments will accompany the regiments into battle in order to be of immediate service. It is planned to have communication with the base hospitals by means of the river and its tributaries. Hundreds of physicians in Russia are reported to have volunteered for service, and many Jews are in the number. The International Committee of the Red Cross has met and made preliminary arrangements for giving assistance to both Russia and Japan in caring for the wounded. Germany has hospitals at Kiao-Chou and at Yokohama, and has notified both combatants that these are at their service for the care of the wounded.

LONDON LETTER.

London's Deficient Ambulance Service.

The need which exists in the metropolis for an efficient ambulance service has been much discussed of late. The matter has been considered by the Metropolitan Asylums' Board, who are willing to supply the demand if the necessary powers can be obtained from parliament. The question was discussed about 10 years ago, but this is a conservative country, and reforms are slow. Apart from the excellent service of horse ambulances of the Metropolitan Asylums' Board, used only for the conveyance of cases of infectious disease to hospital, the only regular service is that of wheeled ambulances used by the police for the conveyance of cases of accident to hospital. But these are much inferior to horse ambulances with accommodation for a nurse as well as for the patient. Yet in many provincial towns excellent ambulance services under the control of the police are provided. For example, there are at Liverpool six fully equipped horse ambulances, which in 1902 attended to 2,759 calls. The ambulance service attached to American hospitals which can be turned out at a moment's notice by telephone does not exist in London. Many hospitals would no doubt be pleased to provide such ambulances, but want of funds and want of space for horses and carriages are bars. The police of the metropolis have been excellently instructed in first aid to the wounded by the St. John's Ambulance Association. In 1901 the number of street accidents in London was 7,995.

A Convalescent Home for Officers of the Army and Navy.

Osborne House, one of the palaces of the late queen, situated on the Isle of Wight, with the magnificent estate attached to it, has been presented by the king to the nation, to be used as a convalescent home for officers of the army and navy. The need for such a home was much felt after the South African war. There will be thirty-eight rooms for single convalescents and five sets of two rooms, or room and dressing room for married couples. For admission the officers must be recommended by the director general of the medical department of the army or navy. There will be a staff of trained nurses. The furniture has been specially devised so as to be as aseptic as possible. Enamel white paint, which contains no lead, is used throughout. The furniture is enameled inside, outside and underneath, so that the absorbent pores of the wood are closed everywhere, and washable surfaces exist on all sides. No angles are allowed; all is rounded off inside the chests of drawers, wardrobes, etc., as well as outside. Around the house are beautiful terraces, a grand stretch of park and sea, and lawn and shrubberies with trees, which break the force of the winds. The climate is that of the south coast, mild and salubrious. For those who can take exercise there is a golf course and twenty-eight miles of good roads for cycling.

The Uses of Radium.

Sir William Ramsay, the distinguished scientist, has delivered a most interesting lecture on radium in which he also dealt with the other radio-active substances, thorium, uranium, polonium, actinium, and an unnamed element discovered by a German professor. Ramsay has found that the gaseous emanation from radium, of which he has collected and measured about the fifth part of a pinhead, is not permanent. It decomposes, and in about a month loses its luminosity. While this is going on the glass tube containing the emanation changes color, in some cases becoming gray and in others purple. The cause of this change is unknown. Radium is constantly decomposing into a luminous gas or emanation, which emanation again decomposes into helium. So far as is known these bodies are elements, and their atom is so heavy that it decomposes. Some investigators hope to accomplish the reverse process, and to build up heavy from light elements. An enormous stride would be made in the knowledge of matter if it were found that elements considered up till now indecomposable and unchangeable are undergoing that universal change which is a fundamental law of nature.

The Vital Statistics of Ireland.

The report on the vital statistics of Ireland, which has just been issued for 1902, is of interest, because it throws light on the social condition of the country. The birth rate has remained practically stationary during the last 20 years; it was 23.5 in 1883 and 23 in 1902. During the same period the English birth rate has declined from 33.5 to 28.5. The lower birth rate of Ireland is explained by the much smaller proportion of women of child-bearing ages in the population—a consequence of emigration. The absence of a fall in the birth rate, which in recent years is so marked, not only in England but in English-speaking countries, is ascribed to the strong religious objections of the Roman Catholics to devices for the prevention of conception. The death rate was 17.5 as compared with 18.2 in an average of the years 1892-1901.

Correspondence.

The Cost of Production of Diphtheria Antitoxin.

DETROIT, MICH., Feb. 17, 1904.

To the Editor:—We have read the editorial, "The Cost of Production of Diphtheria Antitoxin," on page 471 of THE JOURNAL, February 13. It is an interesting article—interesting for what it states, and especially interesting for what it omits to state regarding this responsible, difficult and expensive work. Will you permit us to point out a few of the conspicuous omissions? For example:

Your editorial omits to state what is incontestably true—that the private producers of antitoxin are subject to federal license and to rigid federal supervision, from which the Massachusetts State Board of Health is exempt, since it does not engage in interstate traffic. The representative of the U. S. Public Health and Marine-Hospital Service goes into the biologic laboratories and stables of every private producer in this country and dictates what his equipment shall be. And if the commands of that representative—for commands they are—are not obeyed, the producer's license may be immediately revoked at the pleasure of the bureau.

Your editorial omits to state that the requirements of the bill are so rigid that several of the smaller producers have preferred to abandon the business.

Your editorial omits to state that the private producer must bear the burden of an enormous waste in the form of returned serum. Forty per cent. of his sales comes back for exchange. Every drop of the returned serum is thrown away, as are likewise parts of the expensive injecting device which comes back with the serum.

Your editorial omits to state that each dose of antitoxin sent out by the private producer is accompanied by an injecting device that costs him not less than 23 cents apiece. Taking into account the number of returned packages and the parts of the injecting appliances thus wasted, the actual cost of the device is much greater.

Your editorial omits to state that we are ready and willing to supply the Chicago Board of Health, and every other board of health in the United States, with serum testing 200 units to the c.c., at a price of $0.75 per thousand units, and not at the price of $1.33 which you quote.

Your editorial omits to state that when the physician or the consumer pays $1.33 for a thousand-unit dose of our antitoxin, he receives a serum testing not less than 300 units to the c.c., and that the packages containing the larger doses are filled with the concentrated XX serum—serum which few horses yield, and which is both difficult and expensive to produce.

Your editorial omits to state that it costs the manufacturer something *to obtain and transact* his business. Overlooking that factor, we wonder less at your statement that the current market price "affords a margin larger than would be *deemed absolutely necessary to the profitable and successful* conduct of ordinary commercial undertakings." But the difference between producing cost and selling price is by no means profit. Gross profits are not net profits. Our net profits rarely rise beyond 10 per cent. Do you imagine that "gross profits" and "net profits" are interchangeable terms? Do you make any allowance for the fact that after the expense is incurred, the business gotten and the sale made, 40 per cent. of the product sold comes back, worthless and wasted, for exchange?

We consider your editorial unfair to a class of men who are bearing an enormous responsibility, and who, if they weakly yielded to the clamor for cheap serum, would be mercilessly condemned at the first catastrophe, such as followed fast on the heels of the "municipal enterprise" displayed by the city of St. Louis in the conduct of its own antitoxin plant. As yet, not a life has been lost by the use of contaminated serum, *save where the antitoxin was made in a municipal laboratory.*

Responsibility considered, the manufacture and sale of antitoxin by no means yields the producer a fair profit. If the profit were at all out of the common or above the average, the law of supply and demand would come into play, and capital, seeking profitable investment, would straightway flow into this particular industry. Just at present capital is flowing out of it.

We hope that, in justice to us, you will publish this letter in an early issue of THE JOURNAL.

PARKE, DAVIS & CO.

Marriages.

OTTO V. GREENE, M.D., to Miss Kate Bascom, both of Bethel, Vt., February 24.

HERMAN J. GIERING, M.D., to Miss Agnes Shutler, both of Baltimore, February 6.

JAMES O. SANDERS, M.D., to Miss Frances Rogers, both of Anderson, S. C., February 10.

CLARENCE MILTON SWALE, M.D., to Miss Lillian Gamidge, both of Mason City, Iowa, February 3.

LEWIS L. NEBLETT, M.D., Stayton, Tenn., to Miss Bessie Carlisle of Sadlersville, Tenn., February 10.

GUY SWAN, M.D., Bellefontaine, Ohio, to Miss Grace Ingalls of Huntsville, at Newport, Ky., February 12.

ROBERT JEMISON HARGROVE, M.D., Tuscaloosa, Ala., to Miss Louise Browne of Hattiesburg, Miss., February 9.

EDWARD WRIGHT RUSSELL, M.D., Clearfield, Pa., to Miss Marion Edgerton Carpenter of Dresden, Germany, February 5.

Deaths.

Frederick Granville Winter, M.D. *Long Island College* Hospital, Brooklyn, 1882, of Brooklyn, N. Y., formerly president of the Brooklyn Medical Society, a member of the Medical Society of the County of Kings, and surgeon of the Twenty-Third Infantry, N. G., N. Y., died from the effects of a septic wound, after an illness of eight years, at Kingfield, Maine, February 11, aged 46.

Ephraim P. Russell, M.D. Jefferson Medical College, Philadelphia, 1866, of Hopkinsville, Ky., died at the Walker Sanitarium, Evansville, Ind., February 16, one week after amputation of the right leg above the knee, for gangrene of the foot, the local condition being complicated with serious renal disease, aged 61. He was an active member of the Christian County Medical Society.

Emile A. de Schweinitz, M.D. Columbian University, Washington, D. C., 1894, dean of, and professor of chemistry and bacteriology in the Columbian University; director of the biochemic laboratory of the Bureau of Animal Industry, Department of Agriculture, a member of the American Medical Association, died at his home in Washington, D. C., February 15, aged 37.

Frank Le Roy W. Tetamore, M.D. Long Island College Hospital, Brooklyn, 1882, acting assistant surgeon, U. S. Army, was drowned with a party of eight officers near Manila, P. I., February 10. He was captain and assistant surgeon of volunteers, and a year ago re-entered the service at Caloocan as a contract surgeon.

James M. Laird, M.D. New York University, 1877, an esteemed practitioner of the Kanawha and New River valleys, W. Va., and a resident of Montgomery for twenty-five years, died at Sheltering Arms Hospital, Paint Creek, while under operation for some disease of the throat, February 15, aged 51.

Joseph R. Askew, M.D. University of Pennsylvania, Philadelphia, 1841, died recently at his home in Jacksonville, Ill. At its meeting, February 11, the Morgan County Medical Society appointed a committee to draft resolutions regarding the death of its deceased member.

Maximilian G. Raefle, M.D. Humboldt Medical College, St. Louis, 1861, a surgeon in the Navy during the Civil War, and some-time deputy coroner of New York City, died suddenly at his home in New York City, February 13, from apoplexy, aged 67.

Sereno Edward Dwight Bumstead, M.D. Harvard University Medical School, Boston, 1844, formerly a physician of Port-au-Prince, died at his home in South Framingham, Mass., February 14, from paralysis, aged 81. He retired from practice in 1901.

Charles Augustus Wheeler, M.D. Worcester (Mass.) Medical College, 1857, of Leominster, Mass., a member of the American Medical Association, a veteran of the Civil War, died at the Massachusetts General Hospital, Boston, February 11, aged 67.

Joshua E. Van Camp, M.D. University of Michigan, Ann Arbor, 1870, a member of the American Medical Association, died very suddenly from apoplexy while making a professional call near his home in Carlisle, Pa., aged 60.

Rodger C. Downey, M.D. University of Vermont, Burlington, 1892, a member of the state and county medical societies, died at his home in Middletown, Conn., February 15, from erysipelas, after a short illness, aged 35.

Charles E. Cook, M.D. Chicago Medical College, 1880, some-time coroner of McHenry County, Ill., died at his home in Huntley, February 18, from double pneumonia, after an illness of ten days, aged 51.

Henry Martin Dearborn, M.D. Medical School of Maine at Bowdoin College, Brunswick, 1869, died at his home in New York City, February 16, from pneumonia, after an illness of eight days, aged 58.

John W. Thompson, M.D. Arkansas University, Little Rock, 1887, of Hillsboro, Ark., was shot and killed, February 12, by a brother of Dr. A. A. Finley, who was killed in March, 1903, by Dr. Thompson.

McDuffie Blanchard, M.D. University of Nashville, 1857, assistant surgeon in the Confederate service, died at his home in Columbus, Ga., February 12, from pneumonia, after a short illness, aged 68.

Charles Elliott Denig, M.D. Starling Medical College, Columbus, 1850, surgeon throughout the Civil War, who retired from practice in 1894, died at his home in Columbus, Ohio, February 9, aged 78.

Frank A. Box, M.D. State University of Iowa, College of *Homeopathic* Medicine, Iowa City, 1890, of Pulaski, N. Y., died from pneumonia at the Oswego Hospital, February 11, aged 36.

Joseph Beck, M.D. Physio-Medical Institute, Cincinnati, 1878, died at his home in Eldorado, Ohio, February 17, aged 83.

Lawrence Scott Jones, M.D. Eclectic Medical College of Philadelphia, 1881, died at his home in Harrisburg, Pa., from consumption, February 13, after an illness of one year, aged 40.

Henry Augustine Crary, M.D. Albany (N. Y.) Medical College, 1866, died at his home in Knox, N. Y., December 25, from locomotor ataxia, after an illness of several years.

R. E. Curran, M.D. Louisville Medical College, died at his home in Los Angeles, Cal., February 7, from internal hemorrhage, after an illness of two days, aged 59.

Robert Lautenbach, M.D. University of Maryland, a surgeon in the Army during the Civil War, died from pneumonia at his home in Baltimore, February 16, aged 60.

George E. McCosh, M.D. Bellevue Hospital Medical College, New York, 1866, died at his home in St. Louis, February 13, after an illness of three months, aged 62.

George Beecher Malone, M.D. Detroit Medical College, 1885, of Park Ridge, Ill., died at the home of his son in Chicago, February 17, from pneumonia, aged 54.

Conrad G. Eddy, M.D. University College of Medicine, Richmond, Va., 1900, died at his home in St. Marys, W. Va., February 11, from pneumonia, aged 26.

Adna P. Parsons, M.D. Syracuse (N. Y.) Medical College, 1850, died at his home in Forestville, N. Y., February 13, from pulmonary tuberculosis, aged 87.

Henry Buehler Buehler, M.D. Jefferson Medical College, Philadelphia, surgeon during the Civil War, died at his home in Harrisburg, Pa., February 1, aged 69.

Charles W. Trautwein, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1895, died at his home in Kinderhook, Ill., February 22, from acute nephritis.

Edward C. Bain, M.D. University of Tennessee, Nashville, 1865, died at his home in Pleasant Plains, Ill., February 14, after a lingering illness, aged 61.

Stephen W. Ransom, M.D. Chicago Medical College, 1870, a member of the American Medical Association, died recently at his home in Dodge Center, Minn.

Albert Trenchard, M.D. Jefferson Medical College, Philadelphia, 1870, died at his home in Glassboro, N. J., February 11, after a long illness, aged 60.

Martin Ireland, M.D. University of Wooster, Cleveland, 1847, died at his home in Columbia City, Ind., February 11, from paralysis, aged 82.

Levi Vincent, M.D. Bennett College of Eclectic Medicine and Surgery, Chicago, 1872, died at his home in Weston, Ill., February 12, aged 77.

George A. Blakeley, M.D. Rush Medical College, Chicago, 1885, of Albany, Wis., died suddenly in Chicago, February 3, aged 46.

William S. Charlton, M.D. University of Pennsylvania, Philadelphia, 1883, died at his home in Philadelphia, February 2, aged 46.

Samuel Miller, M.D. Toronto School of Medicine, died at his home in St. Louis, February 14, after a prolonged illness, aged 82.

Martin E. Brackett, M.D. University of Buffalo (N. Y.) 1891, died, January 2, at his home in Clarendon, N. Y.

William B. Brown, M.D. New York University, 1846, died at his home in Greenville, N. C., Nov. 12, 1903.

T. J. Tabor, M.D. American Medical College, St. Louis, 1876, died at his home in Doyline, La., December 17.

Simon J. Seyfert, M.D. University of Pennsylvania, 1871, died recently at his home in Pine Grove, Pa.

George Clinton Hale, M.D., of Catskill, N. Y., died at his home in that place, January 30, aged 71.

Miscellany.

Egg Albumin and Castor Oil in Burns.—A mixture of castor oil with the white of an egg allays the pain more quickly and causes the wound to heal more rapidly than any other application. The eggs are broken into a bowl, and the castor oil gradually and slowly poured in while the eggs are beaten. Enough oil is added to make a thick, creamy paste, which is applied to the burn with a feather. The applications are repeated often enough to prevent their becoming dry or sticky. It is best to abstain from any dressings, leaving the surface uncovered.—*Med. Fortnightly.*

Formaldehyd.—It may not be out of place to warn postmortem examiners and, especially, those who act as such only occasionally, with regard to an interesting action of formaldehyd, which is now largely used by embalmers. For some hours after somatic death, the vitality of the intestine and stomach remains to such a degree that various muscular contractions take place. This is frequently seen on the lower animals, and in one human necropsy, six hours after death and after the occurrence of postmortem rigidity of the voluntary muscles, we noted spastic contraction of the small intestine following the touch of instruments. Apparently formaldehyd either causes such spasm or at least fixes the unstriped muscle in its contracted state. At any rate, the stomach and intestines may be found of board-like hardness in places and with narrowing of lumen at the sphincters and in the course of the small intestine, so as to suggest antemortem ileus to the uninitiated.—*Medical Fortnightly.*

The Marine-Hospital Service as a Field for the Physician.—In a recent address before the students of Jefferson Medical College, Philadelphia, speaking of the U. S. Public Health and Marine Hospital Service, Surgeon-General Wyman said: I know of no medical service in the world which holds out the same facilities for the professional advancement for its officers. It has at least 15 expert bacteriologists. It offers opportunity and encouragement for continued study, free from the petty annoyances and interruptions of private practice. It keeps its officers supplied with the latest special books, instruments, and apparatus, beyond the reach of many recent graduates. Aptitude and ambition to excel in any branch of medicine, surgery or preventive medicine have in it their full chance of fruition. Because of the extension of its functions by recent act of Congress, it is necessarily a growing service. The corps is being gradually but constantly enlarged. The service was by act of July 1, 1902, placed on a broad and strong foundation, and has but just begun its development on its higher plane. It has a fine record and a brilliant future —and it is free from politics.

Investigation of Mineral Water.—Nearly two years ago the Academy of Medicine of Paris published the report of a committee appointed to investigate the qualities of Apollinaris water, and the findings were unfavorable. This was noticed in The Journal, Sept. 6, 1902. There is probably no other natural table mineral water, so-called, so well known as the Apollinaris, and the case excited considerable general interest, especially since legal action was taken by certain parties charging the Apollinaris Company with the offense, under the English law, of selling its bottled water with a false trade description. In order to settle the question, the London *Lancet* sent a special commissioner to the locality of the springs, and his report is published in full in that journal, January 30. It gives an interesting description of the springs and of the method of obtaining and bottling the water. It appears that the carbonic acid which is derived from the water is conducted into a receiver. The water is tanked off, and a slight amount of salt is added, over and above the natural quantity contained, as a precaution against the decomposition of the sulphate of soda contained in the spring. Then the water is passed through a carbonator and the collected gas is forced back under heavy pressure, and it is bottled for consumption. It would appear from this that this commercial article is what it is professed to be, and as evidence of this it is said that water taken directly from the spring does not differ in any respect in taste or quality from that sold. For the reason that we published the unfavorable report, we can in justice only give the other side.

CLIPPINGS FROM LAY EXCHANGES.

SUCCESSFUL DOUBLE NEPHRECTOMY.

"Removed a Child's Kidneys. Unusual Operation Performed. . . . Yesterday Dr. —— performed an unusual operation . . . known as . . . decapulation of the kidneys. . . . Both kidneys were removed, and the child underwent the operation successfully, although there is not much hope of her ultimate recovery."—*Syracuse* (N. Y.) *Herald*, Nov. 29, 1903.

MEDICINE AND MILLINERY.

"Dr. —— has arranged . . . to open an office for the practice of medicine. He will open up a drug store and a millinery store."—*West Plains* (Mo.) *Journal*, Nov. 12, 1903.

WHAT HAD HE AGAINST THE DOCTOR?

Under the headline of "*Things You Want to Know*" the *Norwalk* (Ohio) *Reflector*, Feb. 8, 1904, gives as the leading item: "Dr. ——, a well-known . . . physician, died at Phoenix, Ariz. . . ."

OPENED THE SPICULA.

In a report of an operation for the relief of traumatic epilepsy, the New York correspondent of the *Chicago Tribune* says: "He opened the spicula and a bone . . . was found imbedded in the brain."

DID HIS PATIENTS INVARIABLY DIE?

"Dr. ——, the expert physician . . . is gone and forever at rest from his labors. . . . As a diagnostician he seldom failed. Exceptions are hard to find where postmortems did not prove the correctness of his diagnosis."—*St. Anne* (Ill.) *Record*, Jan. 29, 1904.

SMOOTH OPERATION ON THE KAISER.

A cable dispatch from Berlin to the *Chicago Record-Herald* of November 9, announcing an operation on the throat of Emperor William says: "Professor Schmidt guarantees the statement that the operation went off perfectly smooth, but he emphasizes as a sine qua non that the Kaiser must not talk."

DEATH FROM SPONTANEOUS BIOPLASM.

"Dr. —— has been at —— to investigate the reported death of two children . . . The deaths, Dr. —— says, did not result from vaccination or the virus . . . but from spontaneous bioplasm in the wounds on the arms of the little ones. Dr. —— is convinced that the vaccination was entirely successful. The children are still dead."—*Fort Wayne* (Ind.) *Gazette*, Nov. 16, 1903.

VERTEBRA REMOVED, CLEANED AND REPLACED.

"Remarkable Surgical Operation—Vertebra Removed and Cleaned to Cure Paralysis Following Broken Neck. Sioux City, Iowa, Dec. 21.—An operation having no parallel in the surgical world was performed . . . to-day. A part of the third cervical vertebra was removed, the false growth of tissue was cleaned out and the bone replaced. The patient is doing well. . . . No other case is known in which the cervical vertebra, situated so near the medulla oblongata, has been removed and replaced."—*New York Tribune*, Dec. 22, 1903.

OPERATOR HAD NERVE.

"Dr. —— . . . performed an operation on a . . . woman, which, while it further establishes his reputation as one of the foremost surgeons of the country, stands as one of the most critical and successful ever performed in the history of surgery. The patient . . . came under the knife, with a goitre, a growth in the throat, which subsequent events showed to weigh 8 lbs. and 8 ounces. It had been broken and was in process of disintegration, with her days apparently not numbered beyond a week. It had to be removed. No anesthetic was given, and for 2 hours and 20 minutes the patient was directly under the knife. During the operation the surgeon's touch or scalpel passed by or rested on the common carotid arteries, jugular vein and laryngal nerve. The deviation of the knife a hairbreadth at certain times would have plunged the patient into eternity. When the operation was done not two ounces of blood had been lost and the surgeon retired, completely exhausted, from the table. An indomitable nerve, fautless skill and powerful strength could only have kept him up to the task."—*Shamokin* (Pa.) *Herald*, Nov. 16, 1903.

THE ARMY MEDICAL DEPARTMENT.

The Proposed Modification—New Legislation Now Before Congress.

The following three bills of importance to the medical corps of the Army have been approved by the Secretary of War and forwarded by him for the action of Congress.

ARMY HOSPITAL AND COLLEGE.

A. To appropriate $400,000 for the purchase of land and the construction of an Army general hospital at Washington. The present general hospital there is a small and unsuitable building on the grounds of the Washington Barracks, which likewise occupies space needed for the buildings of the new engineer post there, which is now under construction. It is proposed to make the new hospital a handsome and modern structure, with sufficient space about it for great extension by the erection of temporary wards in time of war. It will be also the home of the Army Medical School, which now occupies cramped and inadequate quarters at the Army Medical Museum. This school is one of the service schools at which officers of the organized militia are by recent Act of Congress authorized to attend courses with the provision that while so doing they "shall receive from the annual appropriations for the support of the Army the same travel allowances and quarters or commutation of quarters to which an officer of the Army would be entitled and also to receive commutation of subsistence at the rate of one dollar per day while in actual attendance." This liberal and important provision for the special instruction of National Guard medical officers will, however, remain inoperative until room for the extension of the school is gained by the construction of the new hospital. Here also will be stationed a company of instruction of the hospital corps and a detachment of the Army nurse corps. The establishment of such a hospital and school was recommended by the Surgeon General as far back as 1862. When carried out it will correspond with the English Army Hospital School established at Netley after the Crimean War, and with the celebrated French Hospital School at Val-de-Grace established more than a hundred years ago. This hospital will have facilities for the treatment of special medical and surgical cases, and will be provided with all kinds of apparatus, which on account of their expense and special character are not supplied to the hospital at Army posts.

THE SURGEON-GENERAL'S LIBRARY BOOK CASES.

B. For the purchase of book stacks for the library of the Surgeon-General's office, $13,000. An appropriation for this purpose has been unsuccessfully asked for for the past six years, and the books of this fine national institution are piled on window sills and on the floor in consequence of the failure of Congress to provide for it.

REORGANIZATION OF THE MEDICAL CORPS.

C. The third and most important measure is for the reorganization of the medical corps with a view to the attainment of the following objects:

1. To increase the number of medical officers sufficiently for them to be able to perform in time of peace all the duties with which they are charged by Army regulations. So far is this from being the case at present that the regular medical corps has to be supplemented by the employment of about two hundred contract surgeons.

2. To correct the injustice done the medical corps by the act for the reorganization of the Army in 1901, by which without a proper consideration for the needs of the medical department the proportion of officers in the higher grades was greatly reduced, and the prospect for promotion in that branch of the service much impaired. As a result the medical department has been unable to fill the vacancies in the grade of lieutenant created by that act, in spite of every effort to attract candidates, and there have been eleven resignations from among the younger men in the corps as compared with one in the same period of time antecedent to that act. In this bill the Surgeon General asks for a proportionate number in each grade corresponding to that given by Congress to the Medical Department of the Navy last year, which gives a rate of promotion corresponding quite closely with that enjoyed by the Medical Department of the Army prior to the Act of Feb. 2, 1901.

3. To modify the existing law as to examination for promotion so as to provide examination before promotion to all grades except the surgeon generalcy.

4. To establish a reserve medical corps into which the contract surgeons now in the service will be commissioned. These

reserve officers will have, while in active service, the rank and allowances of first lieutenants, medical corps, which will give them a more dignified and satisfactory status than that now enjoyed by contract surgeons. It is the desire of the medical department to attract into this reserve corps capable young men who have recently graduated from the best medical colleges, and to give them military experience and, so far as practicable, a course of instruction at the Army Medical School, so that when they return to civil life to establish themselves and build up a practice they will constitute an eligible list of trained medical officers available for service in time of war. These reserve officers will not be ordered to active service except *on their own application and will be eligible for* appointment to positions in the medical service of the organized militia and as United States volunteer officers with higher rank.

The bill is as follows:

A BILL TO INCREASE THE EFFICIENCY OF THE MEDICAL DEPARTMENT OF THE UNITED STATES ARMY.

(As approved by the Secretary of War, Feb. 18, 1904.)

BE IT ENACTED BY THE SENATE AND HOUSE OF REPRESENTATIVES OF THE UNITED STATES OF AMERICA IN CONGRESS ASSEMBLED, That from and after the approval of this act the Medical Department of the United States Army shall consist of one Surgeon General, with *the rank of Brigadier General*; a medical corps and a medical reserve corps, as hereinafter provided; and the hospital corps, the *nurse corps and dental surgeons as now authorized by law.*

SEC. 2. That the medical corps shall consist of 16 colonels, 24 *lieutenant colonels, 110 majors and 300 captains* or first lieutenants, who shall have rank, pay and allowances of officers of corresponding grades in the cavalry arm of the service. *Immediately following* the approval of this act all officers of the medical department then in active service, other than the Surgeon General, shall be recommissioned in the corresponding grades in the medical corps established by this act, in the order of their seniority and without loss of relative rank in the Army, as follows: Assistant surgeons general, with the rank of colonel, as colonels; deputy surgeons general, with the rank of lieutenant colonel, as lieutenant colonels; surgeons with the rank of major, as majors; assistant surgeons who had attained the rank of captain on or before Dec. 25, 1903, as captains; assistant surgeons, with the rank of first lieutenant, who at the time of the approval of this act shall have served less than *three years as such* in the *Regular Army, as first* lieutenants;

Provided, That assistant surgeons who at the time of the approval of this act shall have served three years or more in the Regular Army as such, and who had not attained the rank of captain on or before Dec. 25, 1903, shall, subject to examination, be recommissioned in the medical corps in the order of their seniority, as captains, to rank as such from the date of the approval of this act.

Provided further, That any assistant surgeon with rank of first lieutenant *who has heretofore failed to qualify for promotion* to the rank of captain and is now under suspension shall be recommissioned in the *medical corps* as first lieutenant with rank as such from date of his commission as assistant surgeon, and shall, at the end of his period of suspension, be again examined in accordance with existing law, and if found qualified shall be commissioned in the medical corps as captain with the rank to which he would have been entitled under the terms of this section had he not been under suspension; if he fails to pass such examination he shall be honorably discharged from the service with one year's pay, as provided by Section 5 of this act.

SEC. 3. That promotions in the medical corps to fill vacancies in the several grades created or caused by this act, or hereafter occurring, shall be made according to seniority, but all such promotions and all appointments to the grade of first lieutenant in said corps shall be subject to examination as hereinafter provided;

Provided, That the increase in grades of colonel, lieutenant colonel and major, provided for in this act, shall be filled by promotion each calendar year of not exceeding two lieutenant colonels to be colonels; three majors to be lieutenant *colonels*; *fourteen* captains to be majors; and of the increase in the grade of first lieutenant not more than 25 *percentum of the total* of such increase shall be appointed in any one calendar year:

Provided further, That a first lieutenant *of the* medical corps on the completion of three years' service, including service as assistant surgeon in the *Regular Army*, or as surgeon or assistant surgeon in the Volunteer Army during the war with Spain or since, or on *active duty* as first lieutenant in the medical reserve corps as hereinafter provided, shall be entitled to the pay and allowances *of a captain* of the medical corps, and when the aggregate of his service, either as first lieutenant in the medical corps or as assistant surgeon in the Regular Army, equals three years he shall be entitled, subject to examination, to promotion to the grade of captain in the medical corps.

SEC. 4. That no person shall receive an appointment as first lieutenant in the medical corps until he shall have successfully passed an examination, under regulations to be prescribed by the Secretary of War, before an army medical board consisting of not less than three officers of the medical corps, *to* be designated by the Secretary of War.

SEC. 5. That no officer of the medical *corps shall be promoted* therein until he shall have successfully passed an examination before an army medical board consisting of not less than three officers of the medical corps to be designated by the Secretary of War, such examination to be prescribed by the Secretary of War, and to be held at such time anterior to the accruing of the right to promotion as may be for the best interests of the service:

Provided, That should any officer of the medical corps fail in his physical examination and be found incapacitated for service by reason of physical disability contracted in the line of duty, he shall be retired with the rank to which his seniority entitled him *to* be promoted, but if he should be found disqualified for promotion for any other reason, a second examination shall not be allowed, but the Secretary of War shall appoint a board of review, to consist *of three medical officers* superior in rank to the officer examined, none of whom shall have served as a member of the board which examined him. *If the unfavorable finding* of the examining board is approved by the board of review the officer reported disqualified for promotion shall, if *a first lieutenant or* captain, be honorably discharged from the service with one year's pay, and, if a major or lieutenant colonel, shall be debarred from promotion, and the officer next in rank found qualified shall be promoted to the vacancy. If the action of the examining *board is disapproved by the board of* review the officer shall be considered qualified and shall be promoted.

SEC. 6. That nothing in this act shall be construed to legislate out of the service any officer now in the Medical Department *of* the Army, nor to affect the relative rank for promotion of any medical officer now in the service, or who may hereafter be appointed therein, as determined by the date of his appointment or commission.

SEC. 7. That for the purpose of securing a reserve corps of medical officers available for military service, the President of the United States is authorized to issue commissions as first lieutenants therein to such graduates of reputable schools of medicine, citizens of the United States, as shall from time to time, on examination to be prescribed by the Secretary of War, be found physically, mentally and morally qualified to hold such commissions, the person so commissioned to constitute and be known as the medical reserve *corps. The commissions so given shall confer on the* holders all the authority, rights and privileges of commissioned officers of the like *grade in the medical corps of the United States Army,* except promotion, but only when called into active duty as hereinafter provided and during the *period of such active duty. Officers* of the medical reserve corps shall have rank in said corps according to date of their commissions therein, and when employed on active duty as hereinafter provided shall rank next below all other officers of like grade in the United States Army:

Provided, That contract surgeons now in the military service, who receive the favorable recommendation of the Surgeon General of the Army, shall be eligible for appointment in said reserve corps without further examination.

SEC. 8. That in emergencies the Secretary of War may order officers of the medical reserve corps to active duty in the service of the United States in such numbers as the public interests may require and may continue such officers on such duty so long as their services are necessary:

Provided, That nothing in this act shall be construed as authorizing an officer of the medical reserve corps to be ordered on active duty as herein provided who is unwilling to accept such service, nor to prohibit an *officer of the medical reserve corps not designated* for active duty from service with the militia, or with the volunteer *troops of* the United States, or in the *service of* the United States in any other capacity; but when so serving with the militia or with volunteer troops, or when employed in the service of the United States in any other capacity, an officer of the medical reserve corps shall not be subject to call for duty under the terms of this section:

Provided further, That the President is authorized to honorably discharge from the medical reserve corps any officer thereof whose services are not longer required:

Provided further, That officers of the medical reserve corps who apply for appointment in the medical corps of the Army may, on the recommendation of the Surgeon General, be placed on active duty by the Secretary of War and ordered to the Army Medical School for instruction and *further examination to determine their fitness* for commission in the medical corps.

SEC. 9. *That officers of the medical* reserve corps when called on active duty in the service of the United States as provided in *Section 8 of* this act shall be subject to the laws, regulations and orders for the government of the Regular Army, and during the period of such service shall be entitled to the pay and allowances of first lieutenants of the medical corps with increase *for* length of service now allowed by law, said increase to be computed only for time of active duty:

Provided, That no officer of the medical reserve corps shall be entitled to retirement or retirement pay; nor shall he be entitled to pension except for physical disability incurred while in active duty and in line of duty.

SEC. 10. All acts and parts of acts in conflict with the provisions of this act are hereby repealed.

This bill, as is now the case with all Army legislation, was considered by the general staff, a body in which the medical corps alone of all the great staff departments, has no representation. It was, however, approved in all respects by that body, except that the general staff recommended a reduction in the number in the grades of colonel and lieutenant colonel. In these two grades they were far less liberal to the medical corps than to the engineer corps, for the increase in which they considered a bill at the same time.

Secretary Root *was not* convinced of the wisdom and justice of this reduction, and one of his last official acts was to refer back the bill to the general staff for reconsideration of this point, with *the following endorsement:*

WAR DEPARTMENT, WASHINGTON, Jan. 30, 1904.

I heartily approve this bill in principle. I consider that it will be *greatly to* the benefit of the service to abandon the employment of contract surgeons and substitute in their place regular commissioned officers. I do not think the number to which it is proposed to increase the medical corps is at all excessive. It seems to me that the presentation of the case by the Surgeon General in regard to the necessities of skilled administration of the medical service in time of war is conclusive. It will be easy in time of war to secure an adequate number of physicians competent to treat the sick and wounded, but it will be impossible to secure medical men competent to conduct the administration of the great and complicated medical service unless they are specially trained in time of peace. The lack of sufficient number of such trained officers in the past has caused untold suffering and the sacrifice of many thousands of valuable lives. It is our present duty to see to it that such a condition shall never exist again. I believe that that can be accomplished only by following the course which has now been indicated by the Surgeon General, and approved by the general staff.

On the single question of the relative proportion of majors, lieutenant colonels and colonels which should properly be accorded to the medical corps the Surgeon General wishes to ask reconsideration by the general staff. That single question, with the assent of the chief of staff, will accordingly be relegated to the general staff for further consideration. On all other questions I approve the bill in detail. (Signed) ELIHU ROOT, Secretary of War.

A compromise between the view of the general staff and that of the Surgeon General has been approved by Secretary Taft, which allows the full number asked for by the medical department in these grades, but by reducing the number of colonels and increasing the number of lieutenant colonels makes a proportion corresponding to the other staff corps in the Army rather than to the Medical Department of the Navy. This is acceptable to the Surgeon General. This bill, if adopted unchanged by Congress, will immensely increase the efficiency of the medical corps, and by means of the reserve corps its methodical expansion for war. It also, by substituting for the anomalous and little respected status of the contract surgeon medical officers of positive military rank, secures to the representatives of our profession in the Army a dignified and satisfactory position in the military body.

It is hoped that every reader of THE JOURNAL will interest himself in these important measures to the extent of indicating to his representatives in Congress his approval of them.

SECRETARY TAFT'S APPROVAL.

The following letter from the new Secretary of War bears on the above:

WASHINGTON, Feb 18, 1904.

To the Chairman, Committee on Military Affairs, House of Representatives:—I have the honor to transmit herewith a bill to increase the efficiency of the Medical Department of the U. S. Army, together with the approval by my predecessor, Secretary Root, of the bill in every part except as to the relative proportions of majors, lieutenant colonels and colonels which should properly be accorded to the medical corps.

The question was remitted to the general staff for further consideration, and has been returned with the recommendation that the number of colonels be limited to 12, the lieutenant colonels to 18, with 110 majors and 300 captains and first lieutenants; whereas the recommendation of the Surgeon General is that the colonels number 20, the lieutenant colonels 20, majors 110 and captains and lieutenants 300. It appears that the division of the general staff to which the bill was referred approved the proportion of colonels and lieutenant colonels as recommended by the Surgeon General, but that the War Department general staff as a body, when the exact point was submitted to them, made the recommendation as above. General Chaffee was not present, I am informed, at the meeting of the general staff, and possibly did not have the advantage of all the statements which were made with reference to the proper number of medical officers for each tactical unit in the field. Certainly the evidence introduced by the Surgeon General shows that the number necessary for each tactical unit is considerably greater than that which must have been assumed by General Chaffee in the conclusion which he reached. Of course, I must differ from the opinion of the general staff and the distinguished chief of that body with great diffidence in view of the short time that I have been in the department. I have, however, read the arguments carefully of the Surgeon General and the statement of the third division of the general staff, and also of the chief of staff, and I am bound to say that it seems to me that the arguments of the Surgeon General substantially outweigh those advanced by the chief of staff. The Surgeon General's report shows a complete workable system which the amendment by the general staff truncates and destroys the symmetry of. Then, too, the prospect of promotion which the increased number in the higher grades offers to those who enter the service seems to be absolutely essential to procuring good material for the medical corps. The increased expense in securing a proper medical education in modern days, as shown by lengthening of the term of preparation from two years to four years, and the great professional rewards in civil life make it highly important that there be offered a due prospect of promotion to young men of ability to induce them to enter the corps.

In deference to the opinion of the general staff, however, I have concluded to recommend a reduction in the number of colonels and an increase in the number of lieutenant colonels, so that the bill should provide for 16 colonels and 24 lieutenant colonels, and this I do after a conference with the Surgeon General, who is willing to accept the amendment.

I do not approve that amendment to the law which limits the examination of a lieutenant colonel, necessary to his promotion to a colonelcy, to an examination of his physical condition, his moral character and his past record in the service, and it seems to me that the examinations ought to be continued to the highest rank, except that of the Surgeon General, which grade is filled, of course, only by selection. Such a requirement will have the effect of preventing the upper grades from being regarded as places of leisure and as not entailing the hard, enthusiastic work which is found in the lower ranks.

I have the honor to recommend the passage of the bill amended as suggested. I believe it to be of the utmost importance in securing a proper and efficient medical corps.

I accompany this letter with the bill and with the communications received by me from the Surgeon General, the third division of the general staff and the chief of staff.

(Signed) WM. H. TAFT, Secretary of War.

State Boards of Registration.

COMING EXAMINATIONS.

Regent of the State Board of Medical Examiners of New Hampshire, State House, Concord, March 1-2. Regent, Channing Folsom, M.D., Concord.

Board of Registration in Medicine for Massachusetts, State House, Boston, March 8-9. Secretary, Edwin B. Harvey, M.D., State House, Boston.

Committees of Examination of Connecticut, New Haven, Hartford and Waterbury, March 8. Secretary, Prof. C. A. Lindsly, New Haven.

Maine Board of Registration of Medicine, Portland, March 23. Secretary, A. K. P. Meserve, M.D., Portland.

Regular Board of Medical Examiners for Georgia, Atlanta, March 30. Secretary, I. H. Goss, M.D., Athens.

Correction in Iowa Report.—Dr. J. F. Kennedy, Des Moines, secretary of the Iowa State Board of Medical Examiners, writes that he accredited one candidate who failed in the October examination to Omaha Medical College who was a graduate of Creighton Medical College. The report of this examination was given in THE JOURNAL, Jan. 23, 1904, p. 258.

Association News.

Laryngology Guest at Atlantic City.

Dr. A. Logan Turner, F.R.C.S. Edinburgh, surgeon for diseases of the ear and throat, Deaconess Hospital, Edinburgh, is to be the guest of honor of the Section on Laryngology and Otology of the American Medical Association, and will read a paper at Atlantic City. Dr. Turner's writings are on a variety of laryngologic and rhinologic topics. His work on the accessory sinuses of the nose is regarded as a classic work of reference on that subject, and his article on "The Demonstration of Artificial Edema of the Larynx" is of the same high standard. The Section is fortunate in having secured the attendance of Dr. Turner.

The Public Service.

Army Changes.

Memorandum of changes of station and duties of medical officers, U. S. Army, for the week ending Feb. 20, 1904:

Dean, Elmer A., asst.-surgeon, granted ten days' leave of absence.

Purviance, Wm. E., asst.-surgeon, returned to duty at Chicago from leave. Feb. 16, 1904, reports in temporary charge of C. S. O., Department of the Lakes, Chicago, on account of sickness of Col. Philip F. Harvey, chief surgeon.

Clayton, George R., contract surgeon, relieved from duty in the Philippine Division and assigned to duty at Columbus Barracks, Ohio, where he reported February 17.

Voohies, Hugh G., contract dental surgeon, relieved from further duty at San Juan, P. R., and assigned to station at Fort Hancock, N. J. (now on temporary duty at Plattsburg Barracks, N. Y.).

Navy Changes.

Changes in the medical corps, U. S. Navy, for week ending Feb. 20, 1904:

McClanahan, R. K., asst.-surgeon, ordered to the Naval Hospital, New York, N. Y., for treatment.

Neilson, J. L., asst.-surgeon, detached from the naval station, Cavite, P. I., and ordered to the naval station, Guam, L. I.

Williams, R. B., P. A. surgeon, commissioned P. A. surgeon with rank of lieutenant, from Nov. 17, 1903.

Butler, C. St. J., asst.-surgeon, ordered to the *Constellation*, with additional duty at the naval training station, Newport, R. I.

Marine-Hospital Service.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ended Feb. 18, 1904:

Stoner, J. B., surgeon, to proceed to Cape Charles Quarantine Station and assume temporary charge.

Korn, W. A., asst.-surgeon, granted eighteen days' leave of absence from February 19.

Warren, B. S., asst.-surgeon, bureau letter granting leave of absence for seven days from February 12, amended to read seven days from February 15.

Hanrath, F. R., pharmacist, on being relieved by Pharmacist E. Rogers, to proceed to St. Louis and report to medical officer in command for duty and assignment to quarters, relieving Pharmacist M. Walerius.

Woods, C. H., pharmacist, relieved from duty at Chicago and directed to proceed to Cincinnati and report to medical officer in command for duty and assignment to quarters, relieving Pharmacist E. Rogers.

Walerius, M., pharmacist, on being relieved by Pharmacist F. R. Hanrath, to proceed to Chicago and report to medical officer in command for duty and assignment to quarters.

Rogers, E., pharmacist, on being relieved by Pharmacist C. H. Woods, to proceed to Cleveland, Ohio, and report to medical officer in command for duty and assignment to quarters, relieving Pharmacist F. R. Hanrath.

Herty, F. J., pharmacist, on being relieved by Pharmacist B. E. Holsendorf, to proceed to Boston and report to medical officer in command for duty and assignment to quarters, relieving Pharmacist L. C. Spangler.

Slough, C., pharmacist, relieved from duty at San Francisco Quarantine and directed to proceed to San Francisco and report to medical officer in command for duty and assignment to quarters, relieving Pharmacist M. R. Mason.

Holsendorf, B. E., pharmacist, relieved from duty at Havana, Cuba, and directed to proceed to San Juan, P. R., and report to medical officer in command for duty and assignment to quarters, relieving Pharmacist F. J. Herty.

Mason, M. R., pharmacist, on being relieved by Pharmacist C. Slough, to proceed to San Francisco Quarantine and report to medical officer in command for duty and assignment to quarters.

Southard, F. A., pharmacist, granted leave of absence for one day on account of sickness.

Spangler, L. C., pharmacist, on being relieved by Pharmacist F. J. Herty, to proceed to Tampa Bay Quarantine and report to medical officer in command for duty and assignment to quarters.

Stier, C., pharmacist, relieved from duty at Tampa Bay Quarantine and assigned to duty at Key West, Fla.

Bierman, C. H., pharmacist, granted leave of absence for twelve days from February 8.

BOARD CONVENED.

Board to meet at Washington, D. C., April 4, 1904, for the examination of candidates for appointment as assistant surgeon. Detail for the board: Surgeon D. A. Carmichael, chairman; Surgeon G. M. Guiteras; P. A. Surgeon J. F. Anderson, recorder.

Health Reports.

The following cases of smallpox, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital service, during the week ended Feb. 19, 1904:

SMALLPOX—UNITED STATES.

California: San Francisco, Jan. 31-Feb. 7, 4 cases.
District of Columbia: Washington, Feb. 6-13, 5 cases.
Florida: Jacksonville, Feb. 6-13, 2 cases.
Illinois: Cairo, Jan. 1-21, 13 cases; Danville, Feb. 6-13, 1 case.
Louisiana: New Orleans, Feb. 6-13, 4 cases, 1 case imported.
Michigan: Detroit, Dec. 6-13, 4 cases; at 82 places, Jan. 30-Feb. 6, present.
Missouri: St. Louis, Jan. 30-Feb. 6, 20 cases.
New Hampshire: Manchester, Feb. 6-13, 8 cases.
New Jersey, Feb. 6-13, Camden, 1 case; Trenton, 3 cases.
New York: Elmira, Feb. 6-13, 1 case imported from Cohockton.
Ohio: Cincinnati, Feb. 5-12, 9 cases; Feb. 6-13, Dayton, 18 cases; Warren, 1 case.
Pennsylvania: Feb. 6-13, Allentown, 5 cases; Butler, 1 case; Johnstown, 1 case, 1 death; Philadelphia, 58 cases, 16 deaths; Pittsburg, 10 cases, 2 deaths.
South Carolina: Charleston, Jan. 30-Feb. 13, 16 cases, 1 death.
Tennessee: Feb. 6-13, Memphis, 42 cases; Nashville, 8 cases.
Washington: Tacoma, Feb. 1-8, 1 case.
Wisconsin: Milwaukee, Feb. 6-13, 6 cases.

SMALLPOX—FOREIGN.

Austria: Prague, Jan. 16-23, 7 cases.
Belgium: Antwerp, Jan. 10-17, 3 cases, 1 death.
Brazil: Pernambuco, Dec. 16-31, 28 deaths; Rio de Janeiro, Jan. 10-17, 39 cases, 28 deaths.
Canada: Vancouver, Jan. 1-31, 7 cases.
China: Hongkong, Dec. 26-Jan. 2, 1 case.
France: Paris, Jan. 22-30, 34 cases, 3 deaths.
Great Britain: Jan. 22-30, Edinburgh, 9 cases; Leeds, 1 case; Glasgow, Jan. 29-Feb. 5, 46 cases; Jan. 16-23, Leith, 1 case; South Shields, 2 cases; Jan. 23-30, Manchester, 1 case, 1 death; Sunderland, 1 case; Nottingham, Jan. 16-30, 23 cases.
India: Bombay, Jan. 12-19, 1 death; Karachi, Jan. 10-17, 3 cases.
Italy: Palermo, Jan. 9-16, 1 case.
Malta: Jan. 9-16, 2 cases.
Mexico: City of Mexico, Jan. 10-31, 9 cases, 3 deaths.
Netherlands, Amsterdam, Jan. 16-30, 9 cases, 1 death.
Russia: Moscow, Jan. 9-16, 4 cases, 1 death; St. Petersburg, Jan. 16-23, 4 cases, 4 deaths; Warsaw, Jan. 8-16, 10 deaths.
Siberia: Vladivostock, Jan. 11, epidemic.
Spain: Barcelona, Jan. 31, 16 deaths; Madrid, Jan. 20, epidemic; Santander, Jan. 25-Feb. 1, 8 cases, 1 death.
Turkey: Constantinople, Jan. 17-31, 9 deaths.

CHOLERA—FOREIGN.

Turkey in Asia: Syria and Mesopotamia, Jan. 11, 11 cases, 4 deaths.

PLAGUE—UNITED STATES.

California: San Francisco, Feb. 7, 1 case.

PLAGUE—FOREIGN.

Brazil: Pernambuco, Dec. 16-31, 3 deaths.
Egypt: Alexandria, Jan. 21, 1 case.
India: Bombay, Jan. 12-19, 189 deaths; Karachi, Jan. 10-17, 8 cases, 9 deaths; Madras, Jan. 9-15, 1 death.
Russia: Cronstadt, Jan. 20, 1 death, laboratory infection.
South Africa: Cape Colony, Jan. 2-9, 1 case, 1 death.

Medical Organization.

Kansas.

Clay County Medical Society.—On February 11, the physicians of the county met at Clay Center, and organized a county society on the standard plan, with the following officers: President, Dr. Samuel E. Reynolds, Clay Center; vice-president, Dr. Benjamin F. Morgan, Clay Center, and secretary and treasurer, Dr. Andrew Pearson, Wakefield.

Mississippi.

Lincoln County Medical Society.—Dr. Oliver B. Quin, McComb, councilor for the Ninth District, met the physicians of the county at Brookhaven, February 9, and organized a society on the standard plan, with the following officers: Dr. James W. Bennett, president; Dr. John T. Butler, vice-president, and Dr. Solon G. Wilson, secretary and treasurer, all of Brookhaven.

Montana.

Missoula County Medical Society.—This society was organized at Missoula, December 26, on the standard plan, with 10 charter members and the following officers: President, Dr. George T. McCullough; vice-president, Dr. Joseph A. Tremblay; secretary-treasurer, Dr. Russell Gwinn; delegate, Dr. W. Buchanan Parsons, and censors, Drs. John J. Buckley, Charles Pixley, and John T. Brown, all of Missoula.

New Jersey.

Salem County Medical Society.—At the quarterly meeting held at Woodbridge, February 3, the society adopted the standard plan of reorganization.

Society Proceedings.

PHYSICIANS' CLUB OF CHICAGO.

Monthly Meeting, held Feb. 16, 1904.

Mr. Clarence Darrow, a noted lawyer, defined graft as "the effort of any human being to take from society or from another human being or animal more than he really gives to society in return." Great grafts are done inside the law. The wise grafter never undertakes to get something contrary to the law. He undertakes to fix the law so that he can get something according to the law. It is more profitable and safer. The cheap grafter, who does not understand his business, and does things by retail instead of wholesale, who has little voice in making or administering laws, undertakes to graft contrary to the law. Great capitalists graft inside the law. It is easier for them to choose their agents and their tools to fix the law the way they want it, and they get what they want without running the slightest possible risk. The grafter is a product of his environment. There is considerable grafting in the legal profession. Indirectly, that is what the legal profession is for, said Mr. Darrow. It is a business chosen by certain men because they think by pursuing it they can get more than they can by pursuing any other business they are familiar with. He said it speaks well for the medical profession that there are few physicians in Congress or in legislatures.

Dr. Harold N. Moyer discussed medical graft. He said he had made inquiries from a large number of members of the profession, and has been unable to find anybody who knew anybody who grafted, or knew anything about graft in the medical profession. He has found one or two men who said they knew of somebody else in the profession grafting, but on running the inquiry down, he found it was false, and he received the word of the man himself to authenticate it.

Dr. J. Clarence Webster asked about the Chicago surgeons in high places who contrive with country practitioners to send them patients. Such men existed, and one could put his fingers on them. It is not necessity that stimulates these men to carry out this nefarious practice, which is not only detrimental to their self-respect, but a temptation to weak brothers with whom they come in contact. Within the last month he saw a circular signed by a surgeon who is connected with one of the well-known hospitals of Chicago. This circular was sent around to various physicians in Illinois and neighboring states, offering bribes for patients sent to him. He knows of the same thing having been done by a professor in one of the best medical schools in a neighboring state. These men are not starving. They do not require to do that business, but they do it. What is the explanation? Not necessity, but deviltry—degeneration, and as long as men in high places do this, he said it is absolute folly to expect the struggling practitioners, who are in the position of being bribed, not to be bribed.

Dr. Palmer Findley said the burden of medical graft falls on the young physician and surgeon. He does not think any surgeon has to graft for bread and butter. Going out into a neighboring town two or three months ago to operate on a poor farmer's wife for a small fee, a physician, after the operation, showed him a card from an agent of a surgeon in Chicago, offering 50 per cent. commissions. This practitioner also showed him a letter from a local surgeon, who solicited cases for 25 per cent. commission. Another case was mentioned of a physician in the same town who had gone personally to the attending physician in a case in behalf of a Chicago surgeon, and he had openly declared time and again that he was receiving a division of fees. The remedy should be the one President Roosevelt suggested for trusts—publicity—publicity through organizations, so that it will be impossible for men who are professors in leading medical schools and officers in medical societies to give commissions.

Mr. Wm. H. McSurely defined a grafter as one who allies or attaches himself to some outside interest, some interest apart from the main motive of his life, for the purpose of getting from that outside interest something that will be beneficial to the main motive of his life. He then spoke of lawyers and physicians as church grafters; the society grafters, etc.

Dr. G. Frank Lydston spoke of the physician in politics and public affairs, saying that the physician who devotes a portion of the years of his life to politics and to the public service is forever damned in the eyes of both the public and the medical profession. The reverse is true of the lawyer. In politics the lawyer attracts attention to himself. He said there were very few lawyers who rendered services in the interest of the public without salary, although this was frequently done by physicians.

NORTH BRANCH OF THE PHILADELPHIA COUNTY MEDICAL SOCIETY.

Regular Meeting, Jan. 13, 1904.

Dr. Samuel Wolfe in the Chair.

Physicians' Relations.

The address of the retiring chairman was read by Dr. H. Brooker Mills, who, after remarking on the value of the organization of branches of the county society, urged that many unnecessary complications could be avoided by properly "training" the patient. He condemned commissions and urged that the medical man take sufficient rest to enable him to perform services of the highest character.

DISCUSSION.

Dr. A. M. Eaton urged the importance of thorough organization of the medical profession, believed that more attention should be given to the business side, and also felt that through organization much of the imposition which is practiced by the undeserving on the hospital clinics could be avoided.

The Diagnosis and Treatment of Internal Hemorrhoids.

Dr. Herman A. Brav divided hemorrhoids into (1) capillary hemorrhoids; (2) arterial hemorrhoids, and (3) hemorrhoidal tumors, which may also be termed respectively the first, second and third stages. In view of the fact that these conditions are also accompanied by hemorrhage, pain, protrusion and discharge of mucus, internal hemorrhoids are frequently confounded with cancer of the rectum, polypus of the rectum and prolapse of the rectum. The conflict is particularly apt to occur in children, in whom polypus and prolapse are not uncommon, while internal hemorrhoids are rare. Polypus and prolapse can be distinguished from hemorrhoids by a careful digital examination, which will reveal the presence of a pedicle to which the growth is attached, and malignant disease can be distinguished by the hard growths on the rectal wall.

He reported the case of a woman, aged 70, which had been diagnosed as internal piles, the patient having suffered from rectal hemorrhages and a constant desire to evacuate the bowels. Digital examination in the lateral and semiprone position revealed nothing, but digital examination in the erect position with the patient straining down showed a malignant stricture about four inches above the anus.

The first stage of the hemorrhoidal development is the most difficult of diagnosis, and *in many cases* aid will be secured in this direction by making the examination immediately after the bowels have been emptied by means of an enema and by having the patient strain down.

Treatment should be considered with reference to the cause, which may be either constipation, retroversion of the uterus, foreign body in the rectum, pregnancy, or straining during micturition, as from stricture or enlarged prostate. Palliative treatment is not effective in the third stage, but is successful in the first and second. The cause should always be ascertained and removed, if possible. Constipation should be avoided, the diet regulated and alcohol and tobacco used only in moderation, if permitted at all. Mild aperients, massage of the sphincter, and the injection of two ounces of olive oil at bedtime, are beneficial in regulating the bowels. Hemorrhage is most efficiently relieved by the application of cold astringents. After each defecation cold water should be injected and the addition of 10 grains of tannic acid is very efficient.

As a means of palliative treatment he injects into the pile five to ten drops of a solution composed of one part of pure carbolic acid, two parts of glycerin and two parts of water. He frequently injects two or three tumors at a time, but did not recommend that more than one be injected by the novice, and the sittings should be a week apart. Following this treatment, the tumor gradually lessens in size, and in a few weeks the pain and discomfort will disappear. In the cases of strangulated piles, immediate operation should be performed, but if the patient will not permit this, applications of lead water and laudanum lotions afford great relief and reduce the edematous swelling, so that the piles may be replaced. He described fully the operation he performs. After tying the piles with a ligature, he does not cut them off, but inserts a rubber tube in the rectum and keeps the bowel confined for about four days, after which action is secured by means of purgatives or enema, if necessary. Next to the ligature operation, he believes the clamp and cautery operation as performed by Henry Smith to be the best. The patient should be kept under observation for at least three weeks after the operation, being allowed about the room after the first week or ten days, but should be *in a recumbent position* the most of the time for the balance of the period.

DISCUSSION.

Dr. Collier Ford Martin commented on a method that is of value in some cases, i. e., stretching the sphincter. He was not inclined to view treatment by injection as a palliative measure, but believed that practically all cases adapted to its use should be cured. In fibroid piles, however, the radical operation is very much better. He did not believe that the sloughing following injection was a consequence of this method, but was due to the lack of proper aseptic precautions, or to the use of too *strong a solution or of too much fluid.* It is well in all cases in which there is the least tightness or irritability of the sphincter to divulge the same under nitrous oxid prior to the injection. The injections should be made through a tubular speculum, one at a time, and the sittings should be a week apart. He prefers the weaker solution, and is at present using the French phenol-sodique. The piles usually disappear in about two or three weeks after the operation. He had had no experience with the ligature method.

Dr. Frank C. Hammond stated that he had seen eight cases operated on with the electrothermic cautery, used by

Dr. Andrew J. Downes, and absolutely no pain was complained of.

Dr. Brav did not believe a speculum was necessary to diagnose internal hemorrhoids; he recommended digital examination with the trained finger.

The discussion then left the subject and turned on the presence of pins and needles in all parts of the body, many cases being reported.

Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Colonic Lavage.

The following technic of colonic lavage is recommended by M. H. Mack in *Med. Standard:*

The patient must be placed on his back with the limbs well elevated. The colon tube is passed into the bowel only a few inches; it is not necessary to carry it beyond the sigmoid as the water easily enters the colon with the tube just inside the sphincter. The temperature of the water may vary from that of ice water to 130 F., though it is preferably used at a temperature of 110 to 120 F., in most cases. Hot and cold water may be alternated, if desired, or the hot followed by cold when a stimulating effect is desired. After placing the tube into the bowel, the nozzle of the irrigator is attached, and from eight to twelve ounces of water allowed to pass in, rarely more without giving the patient pain.

The nozzle is then disconnected and the water siphoned out. This may be repeated several times. The patient should be allowed to judge as to the amount of water to let in at one time.

He employs this method of treatment with good success in constipation due to various causes and especially in that due to catarrhal conditions of the bowel, in diarrhea, dysentery, typhoid fever, hepatic atrophy, kidney diseases and other varieties.

Eczema of the Scalp, Eyebrows and Beard.

The following combinations are recommended by *Jour. des Pract.* in the treatment of eczema involving the scalp, eyebrows and beard:

℞.	Olei cadini	ʒv	20	
	Olei amygdalæ dulcis	℥iiss	75	

M. Ft. ung. Sig.: Apply locally; or:

℞.	Zinci oxidi	ʒiss	6	
	Hydrarg. chloridi mitis	gr. xlv	3	
	Adipis	℥i	30	

M. Ft. ung. Sig.: Apply locally.

And for the involvement of the beard the following:

℞.	Zinci sulph.	gr. c	6	65
	Cupri sulph.	gr. xxx	2	
	Croci (saffron)	gr. v		30
	Aq. camphoræ	℥vii	210	

M. Sig.: Dilute with two parts of water and apply locally.

Diseases of Lid Margins.

Wolffberg, in an abstract in *Oph. Record,* recommends the use of benzine and hydrogen peroxid in the removal of scales and crusts from the margin of the eyelids in blepharitis marginalis. Benzine can be used in full strength and is applied by means of a piece of cotton to the slightly everted lid margin. The crusts are easily removed, the ulcers exposed, which renders the application of the yellow salve more productive. The application of benzine may be used once daily. Hydrogen peroxid is also of service, and may be dropped directly on the infected lid margin. He also uses it in the treatment of catarrh of the conjunctiva in combination with cocain.

Malaria.

In the treatment of malaria, Dr. S. Harris, in *Ther. Gaz.,* states that he commences giving quinin in three to five grain (.20-.30) doses every three or four hours just as soon as a diagnosis is made and continues it until the fever subsides, instead of following the usual custom of beginning its administration at the close of the paroxysm. If the patient is seen during the chill or while the fever is at its height and nervous symptoms are present, such as headache, backache, and pain in the limbs, a hypodermic of morphin gr. 1/8 to gr. 1/4 (.0075-.015) combined with atropin gr. 1/150 (.0004) is given along with the quinin. If constipation is present a large initial dose of calomel is given, combined with soda, hyoscyamus and podophyllin, also paying careful attention to elimination by the kidneys, and to combat the intestinal toxemia he combines with the quinin, salol in three or four grain (.02-.015) doses. Saloquinin, which is the salicylic ester of quinin, is sometimes substituted, given in fifteen to twenty grain (1.-1.20) doses every four hours, but it does not, in the author's opinion, possess any advantage over the foregoing combination of salol and quinin. Later in the disease, to combat the severe headache and backache, he recommends the following combination:

℞.	Codeinæ sulph.	gr. ¼-½		015-.030
	Phenacetini	gr. iii-iv		20-.25

M. Ft. cap. No. i. Sig.: One such capsule as necessary to relieve the subjective symptoms.

The following combination is recommended by the author in both the intermittent and remittent forms of malaria:

℞.	Quin. sulph.			
	Salol, āā	gr. xl-ʒi	2.65-4	
	Codeinæ sulph.	gr. iii		20
	Phenacetini	gr. xxx-xl	2-2	65

M. Ft. capsulæ No. xii. Sig.: One capsule every three or four hours.

To insure the solution of the capsule 10 drops (.6) of dilute hydrochloric acid is given after each dose. Or the quinin may be given in solution as follows:

℞.	Quin. sulph.	gr. l-lxxx	3.30-5	30
	Acidi hydrochlor. dil.	ʒiss-iiss	6.-10	
	Tinct. zingiberis	ʒiiss-iv	10.-15	
	Tinct. opii camph.	ʒii-iv	8.-15	
	Syr. limonis	℥ii	60	
	Aquæ q. s. ad	℥viii	240	

M. Sig.: One tablespoonful every four hours in water, taken through a straw.

In those cases where the untoward effects of quinin are sufficient to prevent its use in large enough doses to obtain its full antimalarial effects the following combination is employed:

℞.	Methylene blue	gr. i		06
	Quininæ sulph.	gr. ii		12

M. Ft. cap. No. i. Sig.: One such capsule every four hours.

For the treatment of the anemia following both the intermittent and remittent forms of malaria, the so-called "malarial cachexia," the following combination is recommended:

℞.	Quin. sulph.	ʒiss	6	
	Ferri reducti	ʒi	4	
	Ext. nucis vom.	gr. viii		50
	Acidi arsenosi	gr. i		06
	Ext. colocynth. co.	gr. x-xv		65-1.
	Podophyllini	gr. i-iii		06-.20
	Mellis q. s.			

M. Ft. cap. No. lx. Sig.: One pill after each meal.

As an initial purgative in the treatment of malaria, W. Krauss recommends the following:

℞.	Hydrarg. chloridi mitis	gr. v		30
	Podophyllini	gr. 1/3		02
	Ext. nucis vom.	gr. i		06
	Aloini purif.	gr. 1/3		02
	Pulv. arom.	gr. viii		50

M. Ft. cap. No. iv. Sig.: One every two hours.

If it is necessary for this to be followed by a saline, thiosulphate of sodium is given in doses of two and a half drams (10.) dissolved in a glass of water. As a substitute for quinin in cases of malaria this author recommends euquinin in somewhat larger doses. In his experience it has acted quite favorably, is easily borne by delicate stomachs, and is a good remedy for children.

As a mixture to be used intravenously the following combination is recommended:

℞.	Quin. bimuriatis	gr. vii		50
	Antipyrini	gr. iii		20
	Aquæ	gtt. xx	1	30

M. Sig.: To be injected intravenously.

The antipyrin aids in the solution of the quinin. This solution should not be used in cyanosed cases where antipyrin is non-indicated.

In the latent or masked forms of malaria the following combination is recommended by the author:

℞.	Quin. hydrobrom.	gr. xxx	2	
	Hydrarg. chloridi mitis	gr. v		30
	Pulv. capsici	gr. iss		09
	Pulv. doveri	gr. v		30
	Aloini purif.	gr. 1/6		01

M. Ft. cap. No. vi. Sig.: One every four hours.

J. B. McElroy recommends the dihydrochlorate of quinin as having advantage over the other salts in having a larger percentage of the alkaloid, in being less bulky, more soluble, less liable to irritate the stomach and can be given hypodermically.

By hypodermoclysis fifteen or twenty grains (1.-1.30) of the bimuriate of quinin and urea are dissolved in a pint of normal salt solution, sterilized, and the entire amount given as a saline infusion.

As a tonic and reconstructive in malaria the following is recommended by H. A. West:

℞.	Acidi arsenosi			
	Strych. sulph., āā	gr. i		06
	Chinchonidinæ	ʒiiss	10	
	Ferri sulph. ex sic.	ʒss	2	

M. Ft. pil. No. xxx. Sig.: One to be taken three times a day after meals.

Euquinin, which is quinin carbonic ether, is recommended by *Merck's Archives*, combined as follows, in the treatment of malaria during convalescence:

℞.	Euquinin	gr. c	6	65
	Ferri sulph. ex sic.	gr. xx	1	30
	Acidi arsenosi	gr. i		06
	Pulv. capsici	gr. x		65

M. Ft. cap. No. xl. Sig.: Two capsules three times a day; or:

℞.	Methylene blue			
	Euquinin			
	Pulv. myristicæ, āā	gr. xl	2	65

M. Ft. cap. No. xx. Sig.: One or two, four times daily for two days, then one three times daily.

[The nutmeg seems to prevent the nausea caused by the methylene blue.]

To prevent the subjective symptoms, such as ringing in the ears, the following combination is recommended:

℞.	Quin. hydrochlor.	ʒii	8
	Acidi hydrochlor. dil.	ʒiii	12
	Acidi hydrobrom. dil.	℥i	30
	Syr. limonis	ʒv	20
	Aquæ q. s.	℥iii	90

M. Sig.: One teaspoonful three times a day between the paroxysms.

Erysipelas—Poison Ivy.

A subscriber sends to this department the following formula, a very efficacious one, as shown by his long experience with it, in the treatment of erysipelas:

℞.	Tinct. ferri chloridi	℥vi	180
	Quin. sulph. (to saturation).		

Sig.: Ten drops to be taken every four hours and the same mixture painted over the affected area thrice daily.

He has also derived most favorable results from the following in the treatment of poison from rhus toxicodendron.

℞.	Ext. serpentariæ flu.	℥iii	90

Sig: To be painted over the affected areas three times a day.

Medicolegal.

Eighty Thousand Dollars for Personal Injuries.—In the case of the International and Great Northern Company vs. Moynahan, mentioned Feb. 6, 1904, page 394, Moynahan received $20,000, and not $80,000. The Journal's attention has been called to the fact that an error was made in the original report of the court proceedings.

North Carolina—To Promote Medical Science.—Chapter 666 of the Public Laws of North Carolina of 1903 provides that the professors of anatomy of the several medical schools of the state shall be a board for the distribution of the unclaimed bodies of persons who at the time of death were prisoners under sentence for crime. But the body of a confederate soldier or of the wife of a confederate soldier is to be excepted from the provisions of this act, and the body of no white person shall be delivered to any school for the colored race. The bodies obtained hereunder shall be embalmed before use for dissection.

New York Medical Journal.

February 13.

1 *Conservative Treatment of Some Surgical Diseases of the Renal Pelvis and the Ureter by the Uretercystoscope. F. Kreissl.
2 *Personal Experiences with the Administration of Nitrous Oxid and Oxygen for Prolonged Anesthesia. Prescott Le Breton.
3 *Original Research Regarding Human Perspiration, etc. Julius H. Hoelscher.
4 *Artificial Fluorescence of Living Tissue in Relation to Disease. (To be concluded.) William J. Morton.
5 *Fluorescin in Transillumination of the Stomach. Robert C. Kemp.
6 *Trunecek's Serum. Swithin Chandler.
7 *Brief Review of the Etiology of Yellow Fever. (Concluded.) James Carroll.

1. **Uretercystoscope.**—This instrument is considered by Kreissl from his experience as having had its utility greatly exaggerated; it is useful, but its sphere is limited. It is itself to some extent an irritant in pathologic conditions, and its limitations are marked in cases with reduced bladder capacity, stenosis of the ureteral orifice, distorsions, twists or kinks of the ureter, and blocking of the catheter by pus and blood clots. He, however, finds it possibly useful to some extent in hydronephrosis, pyelitis, pyonephrosis, ureteritis, pyelonephritis, renal retention and colic obstructions of the ureteral lumen by calculi,, blood clots or pus, strictures or displacements and encroachment on the ureter from external pathologic conditions outside. In only a few of these cases can permanent results be obtained by this method, though temporary relief may be more common. He reviews the various methods, and speaks well of the use of the retention catheter in the ureter in some of these cases, such as pyelitis and renal retention. He thinks fistula following various operations on the ureter and renal pelvis will be rarely observed if the catheter is left in the renal pelvis and the ureter for the first three days after operation.

2. **Anesthesia.**—Le Breton describes the method of using nitrous oxid and oxygen for prolonged anesthesia, and tabulates a number of cases where it was thus employed. His conclusions are:

> The use of nitrous oxid and oxygen for prolonged anesthesia is satisfactory, but limited. The wealthy class alone can demand it, because of the cost of materials and the larger fee for the engagement of an experienced anesthetist. The bulky and expensive apparatus, and the difficult method of administration are not inviting, and the occasional lack of smoothness in the narcosis discomfits the surgeon Hence the employment of this method will be reserved for anesthetists in the larger cities, in the case of operations on the extremities or trunk where the condition of the patient demands an anesthesia free from danger and practically free from after-effects. The deservedly increasing popularity of the gas and ether combination predicts a similar popularity of the use of gas, oxygen and ether, when the gases are used until the incision is made and after the suturing is begun, and the ether provides complete relaxation and freedom from cyanosis during the operation proper. The contraindications are chronic alcoholism and well marked arteriosclerosis or cardiac lesions

3. **Perspiration.**—Hoelscher reports experiments on the human perspiration under the influence of drugs and in certain pathologic conditions. After a thorough cleansing, he enveloped his subjects in sterile gauze and over this secured an oil cloth. The subject was then subjected to dry heat not over 120 F. for one to two hours. When the point of tolerance had been reached, the soaked gauze was quickly removed, submitted to pressure, and the sweat collected, the amounts ranging from 3 to 32 ounces. He offers the following deductions from the experiments: 1. The hot air causes an aseptic fever or temperature elevation, despite the antipyretic action of acetanilid, sodium salicylate and quinin. He can not explain why they do not reduce the temperature. Acetanilid has no effect on the normal temperature in healthy persons and acts only in fever. It generally lessens the pulse-rate, decreases heat production and sometimes increases arterial tension. 2. The hot-air bath is of decided value in acute and chronic uremia, shown by the fact that the perspiration contains a considerable excess of urea and nitrogen. He does not recommend it to the exclusion of other measures, but as an important adjunct to treatment. The secondary effect on nutrition should not be forgotten. 3. In articular rheumatism in conjunction with salicylates, the hot-air bath gives more rapid results and lessens cinchonism. 4. Certain types of myocarditis seem to be benefited by the hot-air bath, and he reports a case. 5. Pilocarpin should never be used without the aid of hot applications to the body. So combined, there is no sialagogue and less toxic drug effect, and far more sweating than otherwise. 6. Three cases of catarrhal jaundice were sweated; all the tests failed to show bile pigments, only the epithelial débris containing bile deposits. 7. Modern sugar tests failed to reveal sugar in the sweat from diabetics. 8. A case of chronic constipation and indicanuria did not disclose the presence of indol or skatol in the sweat. 9. As regards the function of eliminating normal and abnormal substances, the skin is not to be compared with the kidneys. 10. Free sweating seems to favorably affect psoriasis, though further study is required, as also the effect on other skin diseases. Lastly, 1,000 c.c. of sweat contains about 11.5 gm. of solids (nearly 3 drams), one-half inorganic and one-half organic, and about .6 gm. (9 grains) of urea and .47 gm. (8 grains) of nitrogen.

4. **Artificial Fluorescence of Living Tissue.**—Morton gives his methods of introducing solutions or mixtures capable of fluorescence into the system, and the employment of an agency, external or internal, to excite fluorescence, either radium or the Roentgen rays. He concludes that artificially produced fluorescence of the human tissues is a well-grounded therapeutic measure. (This paper is to be concluded.)

5. **Fluorescin in Transillumination of Stomach.**—Kemp describes his method of using a solution of fluorescin in sodium bicarbonate solution, taken internally, for aiding in the transillumination of the stomach. He claims brilliant results. He suggests that the use of fluorescin solution, such as he describes, is also worthy of investigation for the purpose of cystoscopy.

6. **Trunecek's Serum.**—Chandler has employed this preparation in arteriosclerosis and asthma from the same cause, rheumatism, cerebral circulatory disturbances, tinnitus, anemia and senile fibrosis. Six cases are reported. It gave good results in rheumatism and arteriosclerosis, and he finds it a very useful aid in arterial hardening and tenseness in cases that required operation. The method of administration was by the mouth, 16 c.c. twice daily. Hypodermically, the dose is 2 c.c. daily. In his hands this method proved itself efficient, and he considers it the surest and best mode of its employment.

7. **Yellow Fever.**—Carroll's lecture is concluded. He gives the results of investigations including his experiments at Santiago, which proved that the infectious agent of yellow fever can be transferred through a filter that is impermeable to ordinary bacteria. Also that the infectious property of blood drawn from a yellow-fever patient is destroyed at a temperature of 55 C. maintained for ten minutes. In conclusion, he calls attention to some early experiments in the beginning of the last century by a student in the University of Pennsylvania, who evidently came very near proving the inoculability of the disorder, though his conclusions were that the disease was neither infectious nor contagious. The experiments were certainly striking ones.

9. ***The Diet of Arteriosclerosis.***—Arteriosclerosis is a condition usually occurring after overexertion or in overfed individuals, and in highly nervous, ill-nourished persons. The dietetic treatment is of importance as bringing about a proper condition of metabolism in the patient. The restrictions for patients suffering from this condition laid down by Coley are, in substance, as follows: The quantity of food should be reduced, not more than one-half or two-thirds of the general average for the body weight being required. The quality is important. The proteids are to be reduced, not excluded. Meat should be taken but once daily and in small amount. The food should be well cooked and large amounts of fat avoided, as well as other undigestible substances. Alcohol, tea, coffee, cocoa, as well as tobacco, cut off or used in extreme moderation. The ingestion of large quantities of fluid should be curtailed. Regulation of meals is important. The breakfast should consist of fruit, cereal with cream, and perhaps an egg poached or soft boiled. Dinner, five or six hours later, shoulld be the heaviest meal, and consist of soup, fresh meat and vegetables, but overfeeding should be avoided, and between dinner and supper another five- or six-hour interval should elapse. The meal should be light, and consist mainly of fruit and cereals. In general, a comparatively dry diet is indicated, and the patient should not eat between meals. Elimination should be kept at its maximum of efficiency.

10. **Rickets.**—While the general osseous changes in rickets are well known and described in text-books, Sobel remarks that the changes in the fingers have been noticed by but comparatively few of the authors. He reports two cases where this peculiarity was noticeable. He thinks the condition is very frequently overlooked from lack of attention, and suggests for it the name "rachitic dacytilitis."

11. **Pneumonia.**—Rochester summarizes the general treatment of pneumonia as follows: 1. The sustaining of the metabolic processes of the individual by the administration of easily digested or predigested foods in small quantities at stated intervals, the administration of large amounts of pure water for eliminative purposes, and the administration of oxygen gas by inhalation whenever the absorbing surface of the pulmonary mucosa is involved to such extent as to interfere with proper metabolic oxygenation. 2. Elimination, (*a*) by the liver and bowel through the vigorous use of calomel and salts; (*b*) by the skin through sweats induced by external heat; (*c*) through withdrawal of blood when indicated by right heart distention. 3. Stimulation of heart by strychnin, alcohol or ammonium carbonate, and in suitable cases by the subcutaneous injection of normal salt solution. 4. The local treatment of the lung by leeching, wet cupping or dry cupping as indicated. He retabulates a series of cases published in his former article in THE JOURNAL of Nov. 9, 1901, and adds a tabulated statement of 42 more cases. Excluding fatal cases over 50 years of age, and delicate, intemperate or complicated cases, Townsend and Collidge had a ratio of 10 per cent. in 1,000 cases treated at the Massachusetts General Hospital. Rochester has a 10 per cent. mortality without excluding such cases, and if he should exclude such, it would reduce the death rate to 2.5 per cent. He thinks, however, since the cases were not selected, most of them being hospital cases, he is justified in concluding that better results were obtained from the method here indicated

than by any other of which statistics are afforded. He gives the details of its application.

12. **Food Preservatives.**—Eccles' article is similar to his former one. He points out the comparative innocuousness of salicylic acid. He says the use of such food preservatives has been increasing for the last thirty years, and public health has been increasing almost with equal steps. He notes particularly the use of beer, in which salicylic acid is largely used, and finds that, aside from the effects of alcohol, the special diseases that can be attributed to preservatives are much less in beer drinkers than in non-drinkers. The users of salicylated and borated food appear to be freer from disturbances of the digestive system than those whose location and habits would seem to contraindicate the suspicion that they use such preservatives freely. The death rate, for instance, of clergymen from diseases of the digestive system is 106.5, while that of saloonkeepers from the same cause is only 60.4. Salicylic acid in beer does not seem to be especially fatal. Moreover, he says, if the oft-repeated charge that salicylic acid interferes with digestion is true, what of it? The claim that rendering part of the food we eat indigestible is injurious to health, is a superstition of so-called sanitary science. In the small amounts in which it is used in foodstuffs it retards digestion but little. When its compensating quality of acting as a stimulant to the stomach is brought into play it overcomes its retarding power and becomes an aid to digestion. In support of this he quotes from Bartholow and Cushny.

Medical Record, New York.

February 13.

13 *Some Personal Observations and Experience of the Schott Treatment of Heart Diseases. William W. Baldwin.
14 *Contribution to the Study of Spondyloze Rhizomélique, with Report of Three Cases. Alfred Gordon.
15 *Antiseptic Treatment of Pneumonia in Infants and Children. S. Henry Dessau.
16 *Hernia in Young Children. W. B. De Garmo.
17 Radiotherapy, with Report of Cases. D. C. Dennett.

13. **The Schott Treatment.**—Baldwin describes this method and its advantages, noticing also the contraindications which are advanced arteriosclerosis, advanced chronic Bright's disease, aneurism of one of the larger arterial trunks, cases of bronchial asthma and chronic bronchitis, all of which indicate a milder and slower course of treatment. While he has never employed this treatment in cases of heart disease complicated by tuberculosis, Bezly Thorne has often employed it thus to advantage. In very grave cases of organic heart disease, where muscle degeneration is far advanced, other remedies should, at least, be tried first. In cases of great anemia and emaciation in which the effervescent baths are not well borne, carefully regulated, mild brine baths have an excellent curative effect. As a general rule, in all the grave cases where the stronger stimulating baths cause palpitation, asthmatic symptoms and cardiac weakening, irregularity of pulse, cyanosis and other unfavorable symptoms, we should return to the mild brine baths for a time. Some patients have too tender skins for any effervescent baths, and, of course, they are contraindicated. He thinks the artificial Nauheim baths are valuable, but if possible he sends his patients for an additional course at Nauheim. The Schott resistance exercises are also described; he thinks every physician should learn to practice them. They can be given before the baths can be safely employed, and, in his judgment, can be continued indefinitely, can be employed to suit almost any indication of general strength or debility, and the patients can teach themselves. They are admirable respiratory exercises, exert a tonic influence on the heart muscle, and must eventually prove of great therapeutic value. Long-continued effervescent baths at first are a mistake. Any half-hearted, pottering method of treatment is also condemned. Extreme care and prudence are necessary in these cases. One should always employ a trained nurse to assist in giving the baths, even when the physician is present.

14. **Spondyloze Rhizomelique.**—The following are the conclusions of Gordon's article:

1. While Bechterew's, as well as Strümpell-Marie's, ideas can not be accepted in the sense of the existence of two sharply defined clinical entities, the other view of considering all cases of spondylosis as an expression of rheumatism for the simple reason that the patient some time during life presented a history of rheumatism, can not be equally accepted. The onset, course, and termination are in some cases not those of rheumatism.
2. A great many cases recorded, if not all, present distinct symptoms of cord involvement showing that the etiological factor is of a more complicated order than one may suppose.
3. Between the types described by Bechterew, Strümpell and Marie there are a great many intermediary forms.
4. Spondylosis is only a symptom of a more complicated disease, the etiological factor of which is not at all elucidated.

15. **Pneumonia in Infants.**—Dessau advocates the use of carbolic acid as an internal remedy for both the bronchial pneumonia and the lobar pneumonia form of the disease, and reports a case as illustrative of its value. In it he gave internally 1 dram of a 2 per cent. solution of carbolic acid every two hours, and had creosote and eucalyptus evaporation in the sick room. He thinks it probably anticipates the crisis, and the actual crisis is converted in a more gradual termination or lysis. There is no doubt, he says, that the remedy is harmless when given in the dose recommended. The early detection of albumin in the urine is a good guide as to favorable or unfavorable prognosis, according to the amount found. The fact that albumin is found is not a contraindication.

16. **Hernia in Children.**—The causes and pathology of hernia in infants are noted by De Garmo, who tabulates the indications for operating in early life as follows:

1. Strangulated hernia—immediate operation.
2. All cases not controlled by truss.
3. Occasional protrusion with threatened strangulation.
4. When truss-wearing causes pain.
5. On children that can not be brought regularly for attention.
6. In all cases of femoral hernias.
7. On all children over 7 years of age.

His prejudice against operating on quite young children has become less every year, but he would not operate on all, because 90 per cent. of the cases under three years of age may be cured by mechanical means and proper care. After the child passes the sixth or seventh year, a non-operative cure is rare. He remarks that strangulated hernia is not as serious a matter in infants as in adults. It rarely happens that proper manipulation under anesthesia can not reduce the hernia.

February 13.

18 *A Case of Gunshot Wound of the Brain. John A. Wyeth.
19 *Prevention and Treatment of Puerperal Infection. Richard C. Norris.
20 *Myxoneurosis Intestinalis Membranacea. C. A. Ewald.
21 Suburethral Abscess. Richard F. Woods.
22 *Value of Histologic Examination in Carcinoma of the Uterus. Brooke M. Anspach.
23 Facial Paralysis. Norton L. Wilson.
24 *Drainage of the Chest in Empyema. Leon Brinkman.
25 Medicus et Medica. (Concluded.) Helen MacMurchy.

18. **Gunshot Wound of the Brain.**—Wyeth reports a case where a spherical bullet had lodged in the skull, and was removed by operation five months later, proper drainage being secured. There had been previously extensive suppuration, and the symptoms more or less correspond. He remarks that the case would probably have done better had immediate search for the bullet been made to remove it earlier. In cases where a bullet has passed through the skull, he would clear out the wounds of entrance and exit, and enlarge these to remove the loose fragments and arrest, by ligation, hemorrhage in the scalp wound and dura. Hemorrhage from the brain substance should not be arrested, for fear of compression by retained clots, but ligation of the extremities may be practiced to diminish pressure in the injured region. When the hemorrhage has ceased, the blood thus retained in the veins may be gradually and carefully returned to the general circulation. Where the foreign body has lodged and is small and no hemorrhage has occurred and no functional disturbance, he would advise careful aseptic treatment of the wound of extrance, enlarging it for the purpose of removing loose pieces and for the assurance that the foreign body has penetrated beyond the dura into the brain. When the missile is of larger caliber or serious symptoms of injury to the brain are present, the wound of entrance should be thoroughly exposed and cleansed, broken pieces of bone removed, and efforts

3. Perspiration.—Hoelscher reports experiments on the human perspiration under the influence of drugs and in certain pathologic conditions. After a thorough cleansing, he enveloped his subjects in sterile gauze and over this secured an oil cloth. The subject was then subjected to dry heat not over 120 F. for one to two hours. When the point of tolerance had been reached, the soaked gauze was quickly removed, submitted to pressure, and the sweat collected, the amounts ranging from 3 to 32 ounces. He offers the following deductions from the experiments: 1. The hot air causes an aseptic fever or temperature elevation, despite the antipyretic action of acetanilid, sodium salicylate and quinin. He can not explain why they do not reduce the temperature. Acetanilid has no effect on the normal temperature in healthy persons and acts only in fever. It generally lessens the pulse-rate, decreases heat production and sometimes increases arterial tension. 2. The hot-air bath is of decided value in acute and chronic uremia, shown by the fact that the perspiration contains a considerable excess of urea and nitrogen. He does not recommend it to the exclusion of other measures, but as an important adjunct to treatment. The secondary effect on nutrition should not be forgotten. 3. In articular rheumatism in conjunction with salicylates, the hot-air bath gives more rapid results and lessens cinchonism. 4. Certain types of myocarditis seem to be benefited by the hot-air bath, and he reports a case. 5. Pilocarpin should never be used without the aid of hot applications to the body. So combined, there is no sialagogue and less toxic drug effect, and far more sweating than otherwise. 6. Three cases of catarrhal jaundice were sweated; all the tests failed to show bile pigments, only the epithelial débris containing bile deposits. 7. Modern sugar tests failed to reveal sugar in the sweat from diabetics. 8. A case of chronic constipation and indicanuria did not disclose the presence of indol or skatol in the sweat. 9. As regards the function of eliminating normal and abnormal substances, the skin is not to be compared with the kidneys. 10. Free sweating seems to favorably affect psoriasis, though further study is required, as also the effect on other skin diseases. Lastly, 1,000 c.c. of sweat contains about 11.5 gm. of solids (nearly 3 drams), one-half inorganic and one-half organic, and about .6 gm. (9 grains) of urea and .47 gm. (8 grains) of nitrogen.

4. Artificial Fluorescence of Living Tissue.—Morton gives his methods of introducing solutions or mixtures capable of fluorescence into the system, and the employment of an agency, external or internal, to excite fluorescence, either radium or the Roentgen rays. He concludes that artificially produced fluorescence of the human tissues is a well-grounded therapeutic measure. (This paper is to be concluded.)

5. Fluorescin in Transillumination of Stomach.—Kemp describes his method of using a solution of fluorescin in sodium bicarbonate solution, taken internally, for aiding in the transillumination of the stomach. He claims brilliant results. He suggests that the use of fluorescin solution, such as he describes, is also worthy of investigation for the purpose of cystoscopy.

6. Trunecek's Serum.—Chandler has employed this preparation in arteriosclerosis and asthma from the same cause, rheumatism, cerebral circulatory disturbances, tinnitus, anemia and senile fibrosis. Six cases are reported. It gave good results in rheumatism and arteriosclerosis, and he finds it a very useful aid in arterial hardening and tenseness in cases that required operation. The method of administration was by the mouth, 16 c.c. twice daily. Hypodermically, the dose is 2 c.c. daily. In his hands this method proved itself efficient, and he considers it the surest and best mode of its employment.

7. Yellow Fever.—Carroll's lecture is concluded. He gives the results of investigations including his experiments at Santiago, which proved that the infectious agent of yellow fever can be transferred through a filter that is impermeable to ordinary bacteria. Also that the infectious property of blood drawn from a yellow-fever patient is destroyed at a temperature of 55 C. maintained for ten minutes. In conclusion, he calls attention to some early experiments in the beginning of the last century by a student in the University of Pennsylvania, who evidently came very near proving the inoculability of the disorder, though his conclusions were that the disease was neither infectious nor contagious. The experiments were certainly striking ones.

Dinner, five or six hours later, shoulld be the heaviest meal, and consist of soup, fresh meat and vegetables, but overfeeding should be avoided, and between dinner and supper another five- or six-hour interval should elapse. The meal should be light, and consist mainly of fruit and cereals. In general, a comparatively dry diet is indicated, and the patient should not eat between meals. Elimination should be kept at its maximum of efficiency.

10. Rickets.—While the general osseous changes in rickets are well known and described in text-books, Sobel remarks that the changes in the fingers have been noticed by but comparatively few of the authors. He reports two cases where this peculiarity was noticeable. He thinks the condition is very frequently overlooked from lack of attention, and suggests for it the name "rachitic dacytilitis."

11. Pneumonia.—Rochester summarizes the general treatment of pneumonia as follows: 1. The sustaining of the metabolic processes of the individual by the administration of easily digested or predigested foods in small quantities at stated intervals, the administration of large amounts of pure water for eliminative purposes, and the administration of oxygen gas by inhalation whenever the absorbing surface of the pulmonary mucosa is involved to such extent as to interfere with proper metabolic oxygenation. 2. Elimination, (*a*) by the liver and bowel through the vigorous use of calomel and salts; (*b*) by the skin through sweats induced by external heat; (*c*) through withdrawal of blood when indicated by right heart distention. 3. Stimulation of heart by strychnin, alcohol or ammonium carbonate, and in suitable cases by the subcutaneous injection of normal salt solution. 4. The local treatment of the lung by leeching, wet cupping or dry cupping as indicated. He retabulates a series of cases published in his former article in The Journal of Nov. 9, 1901, and adds a tabulated statement of 42 more cases. Excluding fatal cases over 50 years of age, and delicate, intemperate or complicated cases, Townsend and Collidge had a ratio of 10 per cent. in 1,000 cases treated at the Massachusetts General Hospital. Rochester has a 10 per cent. mortality without excluding such cases, and if he should exclude such, it would reduce the death rate to 2.5 per cent. He thinks, however, since the cases were not selected, most of them being hospital cases, he is justified in concluding that better results were obtained from the method here indicated

33 *Experimental Notes on the Treatment of Diabetes. Alfred C. Croftan.
34 *Relation of the Medical Department of the United States Army to the Profession. W. C. Borden.
35 The Intestinal and Stomach Reflexes. Albert Abrams.

29. **Kidney and Ureteral Diseases.**—Kolischer calls attention to the good effects of merely mechanical methods in the treatment of kidney and ureteral affections. He thinks mechanical methods are possibly responsible for the relief of symptoms which are ordinarily otherwise accounted for. In cases where no obstruction is present and suppuration has occurred, he thinks the pus and cellular débris may possibly have become attached to the wall and undergo decomposition, leading to the production of toxemia and certain symptoms which continue as long as these remain in place, but mere flushing of these deposits causes a rapid improvement, though the original trouble is not materially influenced.

30. **Typhoid.**—Wells emphasizes the importance of early diagnosis, based on the medical history of the patient, the symptomatology and careful study of the development of the disease from day to day, including examination of the urine, and blood and cultural experiments that will throw light on the subject. and all these should be subjected to a very rigid analysis in every case.

32. **Patellar Fractures.**—Plummer offers the following as a fair statement of the present status of the question of treatment of recent simple transverse fracture of the patella: 1. Operative treatment should never be undertaken unless under the very best conditions for asepsis. 2. Presuming ideal aseptic conditions, not every case should be subjected to operation, but only healthy patients of suitable age, with at least half an inch of separation of the fragments and lateral tears which compromise the "reserve extension apparatus," or in patients following arduous occupations. 3. Operative treatment meets the indications in a way the non-operative can only partially achieve, but good functional results follow the latter as a rule. 4. Early massage in all cases favors the early and complete restoration of function of the joint, and should always be employed. 5. The operation should be an open arthrotomy. 6. Absorbable suture material applied to the soft parts is sufficient in nearly every case.

33. **Diabetes.**—Croftan has found that the normal sugar content of the blood is destroyed on standing at blood temperature, and that the lymph possesses more sugar-destroying powers than the blood. The serum of the blood and lymph possesses no glycolytic power, nor do the red blood corpuscles. The leucocytes, therefore, are responsible. Glycolysis is not dependent on the life of these cells. The sugar-destroying agent is a non-organized chemical body, which he vaguely calls the glycolytic ferment. Its origin is not positively determined, but it is contained in all organs and tissues. The leucocytes probably act as carriers. The pancreas contains no more glycolytic ferment than some other organs, and he thinks that it and the adrenals probably act as regulators of sugar metabolism, and not as generators of a sugar-destroying agent. Their functions, however, are still very incompletely understood. Applying these data to the therapeusis, two paths are open: Either to supply glycolytic ferment in diabetes, or to stimulate the manufacture and liberation of this ferment by the administration of remedies that will so act. The former method has been tried and the results are not satisfactory, though something can still be done. He thinks the use of intravascular administration of zymase and the glycolytic ferment of yeast is promising. The administration of yeast by the mouth is also worthy of trial. The second method, that of stimulating the glycolytic process from within, has occupied him of late, and he has studied various factors to determine the intensity and rapidity of ferment action, such as the temperature of the medium and its reaction, the concentration of the solution in fermentable substances and their splitting products, and the presence or absence of certain chemical bodies (poisons and ions). The optimum temperature for the glycolysis is between 39.8 and 40 C., somewhat higher than the normal temperature of the body. In some institutions the temperature is raised artificially to promote sugar destruction. This is done by means of hydrotherapeutic procedures, and good results are reported. It is well-known, too, that the occurrence of infectious fevers in diabetes is often accompanied by a decrease or even a disappearance of the glycosuria. This, however, may be due to other causes. The reaction of the medium is of great importance. Slight alkalinity is the optimum; slight acidity greatly impairs, and great acidity as well as great alkalinity inhibit the action of the ferment. This may help to explain the good effects of alkali therapy in diabetes, and the tendency to increased glycosuria following diabetic acidosis. The presence of sugar, over 1 per cent. in quantity, retards the ferment action, and the same applies to the presence of splitting products, such as alcohol and lactic acid. There are no practical therapeutic suggestions from these facts. Finally, the effect of certain chemicals (ions) has been studied, and some important results obtained. Three substances should be mentioned as possessing the power of stimulating the ferment to an astonishing degree in very dilute solutions. These are the salicylates of the alkalies, the alkali carbonates (aside from their reaction), and carbolic acid in great dilution. In dilution above ⅛ molecular the tendency of all three substances is to retard; below 1/50th molecular their effect is indifferent, and at about 1/25th their effect is greatest. The suggestion of giving these remedies internally has been followed out empirically, and some authors report exceedingly favorable results with carbolic acid or the salicylates.

Brooklyn Medical Journal.

February.

36 Address, Medical Society of County of Kings. James P. Warbasse.
37 *Beck's Operation for Hypospadias. A. T. Bristow.
38 Normal Involution of Appendix. Robert T. Morris.
39 *Further Observations on the Controlling Influence of Ovarian Plexus. W. L. Chapman and L. N. Foote.
40 *Concerning the Clinical Signs of Ectopic Gestation. Edward J. Morris.
41 *X-ray Therapy—Its Limitations. John A. Lee.

37. **Beck's Operation for Hypospadias.**—Bristow describes Beck's operation of extending the urethra to the normal meatus in cases of hypospadias, and reports a case where he operated three times according to this method. He advanced the urethra each time, but without meeting with complete success until the third operation, mainly because he did not go far enough toward the pubes in the beginning and free enough of the urethra to admit of its proper stretching. The final result, however, was excellent.

39. **Ovarian Plexus.**—A former work by the authors is first mentioned (see abstract in THE JOURNAL, vol. xxxvii, 43, p. 1730.) Chapman and Foote remark further in favor of the conclusion that the ovarian plexus is the controlling nerve supply to the essential female organs of generation. The grounds for this opinion are summed up as based on the following:

1. The anatomical distribution of the ovarian and uterine plexuses in relation to the functions of these organs. 2. The connections of the plexuses with the central nervous system. 3. The connections of these plexuses with trophic nerve centers and the dependency of the organs they supply on trophic nerve action. 4. The histologic structure of the plexuses, i. e., the character of the nerve fibers of which they are composed. 5. The importance of a joint nerve supply to the ovary, tube and uterus which is effected solely through the ovarian plexus. 6. The development of these organs in connection with their nerve supply, on which is bas[illegible] the nerve supply to an organ which is dev[illegible] [illegible]at organ, is its essential nerve supply. 7. [illegible] cases which demonstrate that pathologic co[illegible] [illegible]erve fibers of the ovarian plexus disturb the functions of the ovary and uterus. 8. Experiments on pregnant cats, which showed that electrical stimulation applied to the ovarian plexus produced contractions of the uterus and fallopian tubes.

40. **Ectopic Gestation.**—Morris reports a case and discusses the symptoms. While the three principal signs, according to Vignard, viz., retarded menstruation, sharp colicky and abdominal pain, and small but persistent uterine hemorrhage accompanying them, are convincing when present, the exceptions are so numerous as to render diagnosis very difficult in some cases. The fact that it is not infrequent for a probable diagnosis only of ectopic pregnancy to be made before the abdomen is opened is sufficient evidence of this fact.

41. **X-Ray Therapy.**—Lee thinks that all epitheliomas, no matter of what type, will show a large proportion of apparent cures, even epithelioma of the cervix, and that the *x*-ray method will be the elective one in such cases. In all operable cancers surgery should be the treatment adopted. In small scirrhus where surgery is for any reason contraindicated, he thinks the *x*-ray might be used with favorable expectations, but in large cancers, the more removed with the knife and the less left to be treated by the rays, the better will be the results. There is a large field for investigation in the post-operative treatment of cancers by this method. It is a question, he thinks, whether all cases should be submitted to the rays directly after operation and before the liver becomes studded with nodular growths. In recurrent cancer, suitable cases properly treated will not show as unsatisfactory results as he has been obliged to report in the case here given. He has always believed that there has been too much surgery in recurrences, surgery which has not even the doubtful advantage of prolonging life. Recurrences along the scar, either ulcerative or of the type known as "en cuirasse," are favorable for the *x*-ray. Hardened, pea-like glands in the supra-clavicular region will readily submit to it. Large masses are not so favorable, and the time to treat recurrence is when it is first recognized, and no time should be lost. When involvement of either the liver or lung is shown it is hardly worth while to attempt to use the *x*-rays nor should rapid recurrence in tumor growths be treated. Exceedingly vascular tumors or rapidly progressive cases with a short history are not suitable. It may be stated as an axiom in *x*-ray therapy: The more acute the disease, the more hopeless it is; the more chronic the condition, the greater is the possibility of cure. The *x*-rays, he holds, do not prevent or affect metastasis, and as a palliative measure should only be used for pain. For this they are better than morphin and have none of its disadvantages.

44 *When and How to Operate for Gallstones. Irving S. Haynes.
45 *Extradural Abscess and Mastoid Disease. Seymour Oppenheimer.
46 Typhoid Epidemic in Ithaca. Chauncey P. Biggs.

42. **Fasting in Treatment.**—Sands finds that prolonged fasting is a very excellent treatment, according to his experience, in typhoid fever, and that patients suffering from pneumonia and influenza, as also after severe injuries and after operations, also do better without nourishment for a while. The most convincing results, however, are in the gastro-intestinal disorders, such as typhoid. It is his rule when called to see a typhoid case to tell the family frankly that the patient should be kept on a strict water diet from eighteen to twenty-one days, assuring them of a more comfortable illness and more certain recovery. He finds that this plan relieves the abdominal symptoms, keeps the temperature lower and is otherwise generally beneficial. He summarizes as follows:

> 1. Acute illnesses in general, of any severity, do better without nourishment, for the reason that, on account of the fever and the poison of the disease, the food is not digested or assimilated; and, if not, adds a gastro-intestinal disturbance to the already existing disease. 2. In acute diseases of the alimentary canal in particular, all nourishment should be withheld until complete subsidence of symptoms. It is quite possible for a patient to fast twenty-one days, or even longer, without the development of any alarming weakness. 3. The indications for the allowance of food are the absence of abdominal symptoms, a cleaning of the tongue and a continuously normal or subnormal temperature.

50 Treatment of Chronic Non-suppurative Disease of the Middle Ear. D. B. St. John Roosa.

48. **Opium in Pneumonia.**—Burt insists on the dangers of the use of opium in pneumonia. He thinks of all narcotics it is the one that tells most rapidly on the respiratory nerve centers. If, with a respiration of 60, or even 50 or less in the minute, the nerve centers are sent to sleep by a potent narcotic, it is obvious that the influence exerted at the critical time can not be otherwise than unfavorable.

51 *Some of the Cardinal Points in the Diagnosis of Abdominal Tumors. H. C. Crowell.
52 *Tuberculosis of the Peritoneum. Lewis S. McMurtry.
53 *The Causes of Failure Following Operation for Nephroptosis. Augustin H. Goelet.

51. **Abdominal Tumors.**—Crowell points out the special points in the diagnosis of these growths, and insists on the importance of the general practitioner's co-operating willingly and promptly with the surgeon in the study, diagnosis and treatment of these lesions.

52. **Peritoneal Tuberculosis.**—McMurtry describes the symptoms of peritoneal tuberculosis, and remarks that in a large number of cases of effusion, where the disease was not diagnosticated prior to laparotomy, he has been gratified to see an apparent permanent cure, some of these having been under observation from six to ten years. In a considerable proportion of apparently favorable cases, however, there was no improvement. He thinks in those cases of marked acuteness characterized by high temperature and rapid pulse, both with and without effusion, operation generally fails to arrest the active progress of the disease. Nevertheless the hopeless character under any other method of treatment, and the harmlessness of section under aseptic precautions, justifies, he believes, operation in every case, especially if there is effusion and diagnosis is not absolutely positive. Tubercular invasion of the fallopian tubes and ovaries from the intestinal tract he thinks is more common than is generally supposed. Thorough removal of the invaded structures is usually followed by permanent cure.

54 *Report of 312 Cases of Cataract Extraction with a Small Peripheral Button-hole in the Iris. H. Beckles Chandler.
55 Delirium After Eye Operations. C. E. Finlay.
56 *Ruptures of the Iris. L. Weiss and W. Klingelhoeffer.
57 Sarcoma of the Orbit, Report of a Case Cured by the X-ray. L. Webster Fox.

54. **Cataract Extraction.**—Chandler has operated in over 300 cases on patients over 40 years of age in which he has removed a round piece, 1 mm. in diameter, as near to the root of the iris as possible. This allows drainage and the expressing of the cortical, which always accumulates above and under the iris. In washing out the anterior chamber the fluid used will flow backward through the opening, carrying with it the débris. In operating thus he tries to make his cut exactly in the corneoscleral junction, expressing the lens in the usual manner, but not using force, after the lens is delivered, to keep the iris prolapsed, knowing that he can remove the cortical through the hole. The result is that he has had only three cases of loss of vitreous in 312 extractions and one of these occurred in endeavoring to remove an opaque capsule. The cause of prolapse he attributes to two factors. The most important one is a flabby iris, and the other is tardy closure of the wound. The use of eserin or pilocarpin to tone up the sphincter results in posterior synechiæ in a large percentage of cases, even when atropin is used. In making this small opening it is absolutely necessary to have a forceps the teeth of which are at the tip end, and scissors whose blades are very thin; otherwise it is made larger and further down than intended. He has usually made the opening after having extracted the lens, as it seems that the small amount of aqueous under the iris acted as a buffer and facilitated its extraction.

56. **Rupture of the Iris.**—Three cases are reported by Weiss and Klingelhoeffer, and they tabulate reported cases to ascertain, if possible, the mechanism of the injury. The trauma in the eye was in all cases violent, and where it was possible to tell the direction from which the blow came, the ruptures of the iris were on the opposite side from the place of impact. They criticise the various theories that have been offered, and

explain the laceration by the stretching of the sphincter most severely at the point perpendicular to the direction of the applied force and there ruptures occur. The elasticity of the sphincter must also play a part.

63 Practical Dietetics in the Treatment of Pneumonia. T. J. Biggs.
64 Pneumonia. M. L. Smoot.

58. **Pneumonia.**—Roberts, who has practiced both in the lower country of North Carolina at an elevation of 200 or 300 feet above the sea, and also in the mountain region at from 3,000 to 4,000 feet elevation, finds certain differences in the type of pneumonia in the two sections. The pneumococcus is nearly always present in the mountain region and the cases occur mainly between December and April. He attributes much of the causation to the long cold winters and the impossibility of avoiding dampness. He has found it following influenza more than any other disorder, and has never seen it do so anywhere to such an extent as there. The alcohol complications of pneumonia are not so common, as the people are not generally habitual drinkers, and the epidemic feature is not pronounced. The most serious complications are those of the heart, which are very frequent, and the other complications, gastric and bowel troubles, are less troublesome than elsewhere. The mortality, he thinks, is not greater in the mountains than in the lower region. His own ratio in the Eastern part of the state was from 10 to 12 per cent. while in the mountains he thinks it will not exceed 1 in 8.

73 *The Temperature as a Guide to the Existence of Suppuration. Lyman Allen.

73. **Temperature in Suppuration.**—Allen notices the lack of relation between temperature conditions and suppurative processes. The latter, he finds, are often unattended by fever, even when acute, and the absence of fever must have little weight in the diagnosis of suppuration. Since a rise of temperature above 100 F. occurs in about two-thirds of all aseptic cases, the presence of fever alone is of little value in making a diagnosis of suppuration.

74 *Observations on Alopecia Areata with a Report of Six Cases. Edward Melchers.
75 Milk as a Carrier of Disease. C. Longfellow.
76 "Fersan," a Valuable Addition to Our Materia Medica. Charles D. Aaron.

74. **Alopecia Areata.**—Melchers describes cases and discusses the condition. He concludes that both the neurotic and parasitic disease are not conditions of the hair, but of the hair follicles and papillæ. The real parasite can be found only in sections of the scalp affected with progressive alopecia, and only by competent bacteriolgists. Most cases are parasitic, and ten or twenty local applications of trikresol will usually effect a cure. Creolin is equally good, but has the disadvantages of stickiness and staining qualities. In the neurotic variety, however, these remedies are of little use. Electricity and general and constitutional treatment are advised. He says the records show a great many cases of alopecia areata, especially in France, which can be traced to the hair brush and comb of the barber shop. He hopes to see a law passed compelling the barbers to disinfect their toilet utensils by formaldehyd gas. In conclusion, he quotes from Hyde as to the moral effect of alopecia on the individual and the need of the supporting assurances of the physician.

79. **Pretyphoid State.**—The condition of general gastrointestinal ill health that sometimes precedes typhoid is noticed by Rudolf. He has had in his experience a number of cases where typhoid fever set in, generally of a severe type, after such a preliminary. Several cases are reported. The possibilities are that the lowered state of health, especially the gastro-intestinal disturbance, predisposes to typhoid infection by lowering the general or local resisting power, or that the typhoid bacillus may be in the intestines for weeks setting up a certain amount of disturbance until, either on account of increased virulence or the lowered resistance of the host, true typhoid fever occurs. As regards the first of these possibilities, it is favored by the fact that gastrointestinal disturbance predisposes to Asiatic cholera and dysentery, and it is not unlikely that it may also predispose to typhoid. It was noticed in the recent British campaign that the soldiers suffering from catarrhal bowel affections were the most prone to typhoid. The second possibility seems to him hardly as well supported by facts, though there are still some that favor it, such as the diarrhea that occurs during Asiatic cholera or during typhoid epidemics, which are not identifiable with the true disorder. He thinks, however, that the balance of evidence is in favor of the first proposition, that the condition of ill health lowers the resistance and favors invasion by the typhoid germ.

1 (XXIV, No. 3.) *Des indications thérapeutiques dans la cholelithiase infectée. A. Chauffard.
2 L'hypotension arterielle chronique. A. Ferrannini. Abstract.
3 (No. 4.) *La coloration vitale des tissus et des bactéries pour augmenter la pénétration et favoriser l'action curative des rayons chimiques. R. Odier (Geneva).
4 Sigmoidite et perisigmoidite. F. Lejars.
5 Texte de la nouvelle Convention Sanitaire Internationelle portant règlement pour prévenir l'invasion et la propagation de la peste et du choléra. (Commenced in No. 3.)

1. **Medical Treatment of Infectious Cholelithiasis.**—Chauffard believes in operating on such cases as the routine procedure, but some are occasionally encountered in which operation is contraindicated or temporizing is allowable. He dislikes to operate, for instance, on women between 50 and 60 who are chronically addicted to lithiasis, obese, the abdomen fat and flabby, the myocardium soft and hypotonic, with generally a tendency to varicose veins and a little sugar or albumin in the urine. The organism has little resistance and the abdomen is a bad one for surgical intervention, while such patients can be cured by medical treatment. He describes other types of moderate intensity in which medical treatment should be tried first, guided by the type of the fever, intermittent, remittent or continuous, by the type of the leucocytosis, the curve generally paralleling that of the temperature, by the retention of bile and the local signs indicating a tendency toward suppuration which forces the surgeon's hand. He argues that an infectious gallstone affection is comparatively free from the dangers surrounding an appendicitic one. It does not develop so insidiously, and the evolution toward suppuration can be detected. A still further difference between the two is that there is no effective medical treatment for appendicitis, while that for infectious cholelithiasis is very promising. It consists in the application of ice to the gall-bladder region or hot compresses if the ice is not tolerated. The first indication is to put the patient on an exclusive milk diet or in severe cases allow nothing but water for twenty-four to forty-eight hours. Diuretic teas may be used to advantage. The biliary passages are then to be sterilized by salicylic medication, for which he prefers sodium salicylate associated with salol and betol (naphthol salicylate). He gives three doses in the twenty-four hours of a combination of the three in equal parts, 1 gm. each. When the infectious symptoms have subsided he returns to the systematic preventive medication with which he keeps his patients free from recurring liver colic. He accomplishes this with small doses of sodium salicylate associated with sodium benzoate or Carlsbad salts, and "Harlem oil."

3. **Staining Tissues and Bacteria to Increase Effect of Chemical Rays.**—Odier has become convinced that the chemical rays

penetrate into and affect living tissues and bacteria in a different degree according to their color. The blood protects the tissues from their action and has to be expelled from the part before light treatment is effectual—this is not due to the composition of the blood but to its red color. If the blood were blue the tissues would be unprotected and the light rays would have intense penetrating power. He has found from his research that a combination of 1 per cent. methylene blue, gentian violet and thionin stains electively the protoplasm, nuclei and chromatin of living cells. They take up the stain better when a small percentage of cocain is added as it renders the cells more tolerant of the stains. He also heats the liquid always to 35 or 38 C. Tests of the chemical rays directed on tissues thus previously stained show that their penetrating power is immeasurably enhanced. Photographic plates are affected in twenty seconds through the abdominal wall of dogs and in one minute through the skull of a cat. [The principle seems to be similar to that recently promulgated by Dreyer and mentioned editorially in THE JOURNAL of February 13.—ED.] Odier has applied these premises in therapeutics, and reports 3 cases of erysipelas and several of furunculosis treated according to them. The results were so striking that before waiting for further confirmation he thinks he is justified in calling the attention of the profession to them. He cured the erysipelas by painting the lesions with a mixture of gentian violet and methylene blue (the true methylene blue, a tetramethylated chlorid of thionin), exposing them afterward for fifteen to twenty minutes to the light of an arc lamp. A large furuncle on the back of a dog was cured by three exposures for thirty minutes to the arc light after injecting into the lesion .5 c.c. of warm artificial serum containing 1 per cent. methylene blue and the same amount of cocain. Furuncles on the back of the neck rapidly healed when painted with a mixture of gentian violet and methylene blue, and then exposed to ordinary daylight. He describes his method of expelling the blood from the part to be treated, with one or two ligatures or by compression with a metal ring or rings. Addition of even a small amount of methylene blue to a culture of the diphtheria or tubercle bacilli or certain kinds of streptococci, augments the bactericidal power of the light to a marked degree.

10 Ueber Kompressions-Stenose des Oesophagus, verursacht durch ein Aneurysma der Aorta descendens. W. Plitek.
11 Bemerkungen zu: van Spanje, Das Manometer bei der Capacitäts-Bestimmung des Magens (of stomach). G. Kelling.

6. Emptying of Stomach in Relation to Acid Formation.—Meyer had occasion to study a number of healthy subjects on whom lavage of the stomach was systematically performed for other purposes. He could not detect any connection between the emptying of the stomach and the normal, subnormal or hypernormal secretion of acid.

7. Absorption of Iodin from the Stomach.—Inouye's experimental tests showed that iodin may be absorbed from the stomach in dogs and cats, but not in man, rabbits or guinea-pigs. The iodin reaction appearing in the saliva indicates that the stomach content has been passed far along into the small intestine in man. In rabbits the reaction could be obtained in five minutes at a distance of 40 to 60 cm. in the small intestine, before it could be detected in the saliva. The results of the tests in rabbits coincided with those observed in man. The iodin reaction is retarded in both when the stomach contains food. As a whole the findings indicate that potassium iodid passes rapidly along into the intestines in normal conditions, and consequently the Penzoldt-Faber test—the time of the first appearance of the iodin reaction in the saliva—may be regarded as a valuable indication of the gastric motor functioning. The iodin salts are gradually decomposed by hydrochloric acid, but the proportion in the normal gastric juice is too small to produce any appreciable effect in less than an hour.

8. Diagnostic Significance of Splashing Sound.—Gockel relates the particulars of 7 cases of cancer of the stomach in which the diagnosis was suggested by a splashing sound at the first examination (the stomach not empty), and only perceptible with the stethoscope. Other symptoms of a cancer were lacking in some. The discovery of the splashing sound was a warning to repeat the examination several times, on the fasting stomach. In one case this symptom, with stagnation, lack of HCl, lactic acid after oatmeal gruel taken after thorough lavage of the stomach, compelled the diagnosis of cancer of the stomach. The patient refused the advised operative intervention. A palpable tumor did not develop until six and a half months later, when the operation revealed an extensive carcinoma at the pylorus with numerous metastases in the glands. In 2 other cases, after evacuation of the stomach and palpating with the patient reclining first on one side and then on the other, the presence of a tumor was discovered in addition to the stagnation and splashing sound. By this change of position it may be possible to palpate a tumor, which in the dorsal decubitus and in narcosis is inaccessible to palpation. In another case the presence of the splashing sound, the stomach fasting, with other symptoms, enabled the diagnosis of a stagnation insufficiency of the intestine to be established and the carcinomatous stenosis to be located at the ileocecal valve. Another case simulated spastic obstipation, but the stenosis near the cecum was finally differentiated by the absence of colic suggesting appendicitis, and the few or no disturbances accompanying the daily stools, while retention of stools induced pains in the lower half of the abdomen, with occasional vomiting. Further evidence of stenosis was afforded by the alternate softness and distension of the abdomen, the discovery once of a rigid loop in the ileocecal region, and the splashing sound, the stomach fasting, after ineffectual "expression" of the stomach. The assumption of a circular carcinoma in this case was based on the age of the patient—54—the absence of any symptoms of inflammation at the time or previously, and the lack of any palpable tumor. He emphasizes the importance of the splashing sound for those cases in which there are no other symptoms indicating stagnation in the gastro-intestinal tract. Its discovery once should compel further and repeated investigation, the stomach empty. If the splashing sound be constantly present, the stomach empty, stenosis of the stomach may be excluded, and the diagnosis of stagnation insufficiency in the intestines be assumed as probable or certain. If the splashing sound can not be detected by succussion, palpato-percussion or change of posture, auscultation of the abdomen with the stethoscope is still liable to reveal it. When detected it should suggest the possibility always of stagnation insufficiency of a malignant or benign nature in the gastro-intestinal canal. The typical sound resembles that made by shaking a bladder or bottle half filled with air and half with fluid. In his cases described, some of which had been long under observation, the first appearance of the splashing sound after a period of obscure symptoms which had suggested the diagnosis of stenosis, was the first positive sign that justified operative intervention. The location of the sound was the guide to the seat of the lesion in some cases.

9. Mette's Quantitative Pepsin Test.—Kaufmann tabulates the particulars of 72 cases of various affections in which comparative tests of the pepsin were made by the modified Mette test and the biuret test. He thinks that the values expressed in figures are much more convenient for purposes of comparison than the tints of the biuret test. The values found with both tests ran exactly parallel.

12. **Actinomycosis or Osteomyelitis?**—Bergmann describes the case of a robust man of 29 who had been kicked in the knee by a horse five years before. The gaping wound did not heal, and the bottom showed at first a dirty greenish-yellow tint. Under bichlorid dressings the wound healed, but a swelling in the parts persisted, and numbness at first was followed by pains. He was treated on the assumption of osteomyelitis for a year or two, until Bergmann noticed that the affection had commenced after the usual age limit for osteomyelitis had been passed; also its gradual, chronic course, the relative good health otherwise of the patient for four years, and the afebrile development of redness of the skin and fluctuation in the swelling in the fifth year. He then diagnosed actinomycosis, and soon cured the patient by appropriate excision and curetting. Staphylococci were found with actinomyces in the lesion, and the former were probably responsible for the enlargement of the inguinal lymphatics observed at the time and spontaneously subsiding after removal of the focus below.

14. **Therapeutic Notes.**—Sigel publishes the results of years of careful tests and experiences with various new therapeutic preparations.

16. **Outlining the Heart.**—Rosenfeld has been studying the various methods in vogue *for determining the outlines of the heart.* His research was conducted at von Leyden's clinic and on the cadaver outside. He thinks Smith's method is liable to induce error. The technic which he regards as most reliable is light finger percussion, radiating from the area of greatest dullness in all diameters. The absolute limits are then determined by percussion, noting the sensation of resistance to the touch, percussion proceeding likewise in this case from the center of dullness to each side. Better results are obtained thus than by commencing where the dullness is less marked. Normally, the right limit of the heart extends about 1 cm. beyond the right margin of the sternum, but this may vary by .5 to 1 cm. On the left, the heart limit is about .5 cm. inside the nipple line. For this palpatory percussion he prefers the old Skoda hammer or the Seitz and Struck plessimeter (4.5 cm. by 1.5 cm.), which is more reliable than the flat plessimeters. He places the third phalanx of the extended finger on the head of the hammer and percusses thus, or the finger can be used instead of the plessimeter. The sensation of resistance thus obtained enables the outlines of the heart to be determined with surprising accuracy. The findings are not confused by the heart sounds, etc., as by other technics.

18. **Treatment of Puzzling Knee Affections.**—The cases to which Hoffa refers are those which have hitherto been classed as neuralgia of the knee. He has found that in many cases the apparent neuralgia is due to atrophy of the quadriceps, to internal derangement of the joint or to a lipoma or free body in it. Treatment depends on correct differentiation, and the results are most gratifying. The quadriceps exerts traction on the capsule, and if this muscle is atrophied the capsule lies loose, and is liable to get between the patella and the condyle of the femur or between the condyles of the tibia and femur. This pressure on the capsule causes the pain, but six weeks of treatment by massage and exercises of the atrophied quadriceps will completely cure the trouble. Treatment addressed to the joint itself, immobilization, baths, etc., only fosters the evil by increasing the atrophy of the muscle. The second cause of the so-called knee neuralgia is the laceration or displacement of a meniscus, or of both, from rupture of the attaching ligaments. The most frequent form is the detachment of the anterior insertion of the internal meniscus from the tibia. The trauma causing the rupture may have been trivial, but the joint swells afterward and is painful; the subject walks on the toes of the foot. Under repose, compresses and massage, the soft, elastic swelling subsides, and the joint returns apparently to normal. Now and then, however, sudden attacks of pain and interference with walking are noted after climbing stairs or other quick movement. The pain is sometimes sudden and intense. The joint appears normal on inspection, but palpation of the space between the condyles of the femur and of the tibia is extremely painful. Local sensitiveness at this point is characteristic and differentiates the trouble, although the displaced meniscus may sometimes also be palpated when the knee is stretched, disappearing again as it is flexed. In recent cases it may be possible to reduce the displaced meniscus, but if conservative treatment is not effectual, it should either be sutured in its place or removed by a "fingerless" operation. The third form of these affections is the presence of an inflammatory fibrous hyperplasia of the fat tissue normally to be found under and on both sides of the patellar ligament. This excess of fat tissue gets caught between the working parts of the joint and causes intense pain. The joint is swollen, and below and on both sides of the patella there is a pseudo-fluctuating doughy swelling lifting up the patellar ligament. The proliferating masses should be removed after failure of conservative measures. Sometimes two or more of the above causes combine to make trouble. Patients belonging to these categories frequently go for years from one physician and watering place to another, while a prompt cure may be realized by the interventions described.

20. **Essence and Treatment of Gout.**—Falkenstein presents arguments to sustain the view that gout originates in the stomach, and is primarily due to some disturbance in the gastric glands which secrete hydrochloric acid. He is a victim himself, and states that for more than two years he has been taking daily, without intermission, forty to sixty drops of pure hydrochloric acid, that is, 3 to 5 gm., in a glass or two of carbonated water. His dyspepsia has completely subsided, and the old attacks of gout have never returned, only an occasional mild pain reminding him of the existence of his gout which had previously tormented him for twenty-three years. His personal experience has been corroborated by that of a large number of patients treated in the same way. He cites a number of facts published of late years which support this theory, and explains the rarity of gout in children and in warm climates by the simpler food, the constant exercise of children and elimination by perspiration in the tropics. He thinks that colchicin is harmful, as it arrests the commencing dissolving process and restores the *status quo ante*, thus aborting an existing attack, but providing aggravated conditions for the following ones. Alkalines are also distinctly injurious, he believes.

23. **Syphilis and Tabes.**—When the connection between syphilis and tabes was first suggested, Erb was skeptical, but he has been industriously collecting statistics since, and now announces that the percentage in his latest series of 400 cases proves to be the same as in the earlier ones. These statistics include only educated men above the middle class, as he considers this material the only one reliable for such studies. Out of a total of 1100 cases of tabes, he found 89.45 per cent. with an unmistakable history of syphilis or

chancre, and in the remainder, syphilitic antecedents were probable in all but 2.8 per cent. He thinks that in this small minority, although the syphilitic origin is non-proven, yet that it is in the highest degree probable. His extensive article analyzes his experience with venereal disease in general. He has made a practice of examining for venereal disease all his male patients over 25, and has found that out of 600 educated men of the upper classes, 43.3 per cent. were absolutely free from venereal disease of any kind. Only 50 per cent. of the 600 had had gonorrhea. He found among 50 tabetic subjects that 90 per cent. had had gonorrhea, including 5 with no manifest evidences of other venereal disease. In conclusion, he critically reviews the various publications on the subject of syphilis and tabes in the last few years. The rarity of tabes in uncivilized countries may be due to its non-recognition. The question is to decide what factors intervene in these places to prevent the development of tabes from syphilis. No land has yet been found where tabes prevails and syphilis is unknown. In regard to treatment, his experience includes multitudes of cases of tabes practically cured by energetic specific treatment with Hg and iodin, but in a large number of others the progress of the tabes was not arrested by treatment.

24. **Etiology and Treatment of Tabes.**—Lesser pleads for more careful postmortem examination of tabetics. He classifies the lesions of syphilis as papulous or secondary; gummatous or tertiary; interstitial or quartan. The third phase is frequently skipped. He regards tabes as primarily an interstitial process with secondary ascending degeneration of the nerve fibers, the whole to be classed as one of the quartan manifestations of syphilis. The papulous stage responds to mercury; the gummatous stage to iodin, but the interstitial stage is refractory to both these drugs. In 96 cases of tabes, he found an aneurism eighteen times, and cites this fact as the keystone of his argument. It establishes a parallel between the syphilitic interstitial inflammation leading to aneurism and the same process in another organ entailing tabes, both quartan manifestations of syphilis, and both most liable to develop in subjects who have not presented tertiary manifestations. Tabes is most rare in countries where the tertiary manifestations are most common and severe.

25. **Bullet Wounds of Pancreas.**—Borchardt's patient was dismissed cured thirteen weeks after a bullet wound of the tail of the pancreas with alarming hemorrhage from the lacerated splenic vessels. Fourteen other bullet wounds of the pancreas are on record, with only 4 recoveries. His is the only case of recovery after injury of the splenic vessels. He mentions that he always makes a practice of examining the pancreas whenever the abdominal cavity is opened on account of a bullet wound. He cites the tragic fate of President McKinley as an illustration of the ease with which such an injury may be overlooked. Wounds in the pancreas tissue bleed very little, and the hemorrhage can be readily arrested with tampons. Bleeding from the injured vessels of the hepatogastric ligament is alarming, but can soon be controlled by a few ligatures. In case of a bleeding wound in the liver, he has found it possible to arrest the hemorrhage by pressing iodoform gauze on the bleeding surface, fastening it with a few deep stitches. In order to prevent the escape of pancreatic juice into the abdominal cavity, he thinks it is necessary to wall off the organ with tampons to promote formation of adhesions and divert harmful secretions outward. Suture of the wound alone is unreliable. In regard to acute hemorrhagic (not infectious) pancreatitis, he comments on its liability to recurrence. In case the general condition allows an operation, he would tampon the bursa omentalis through the gastrocolic ligament and introduce a second protecting tampon behind the omentum, colon and stomach, making an artificial anus in case of paralysis of the intestines. Intervention on the pancreas itself in the acute stage has always been followed by the death of the patient. The particulars of the 15 cases are appended.

26. **Origin and Prevention of Tuberculosis.**—Behring's new views on this subject were summarized in The Journal on page 994 of the last volume. He here recapitulates them in forty propositions. The campaign against tuberculosis based on these principles should aim to prevent ingestion of tubercle bacilli with the food, especially during early infancy, and at the same time supply tubercle-bacillus antibodies in the milk for the purpose of rendering harmless any tubercle bacilli that may be inhaled. The production of milk absolutely free from these bacilli will be possible if the immunization of cattle, according to the method he has devised, realizes present anticipations. To complete the immunizing treatment of infants with the antibodies, it may be possible to add to those already in the milk others derived from outside sources.

36 *Zur Lehre von den antitoxischen Seris. F. Wechsberg (Vienna).

29. **Intracellular Constituents of Typhoid Bacillus.**—Macfadyen states that inoculation of animals with disintegrated bacilli is not accompanied by the usual local reaction, while absorption proceeds more rapidly. He has succeeded in producing an antityphoid serum which has both bactericidal and antitoxic power. His technic includes freezing the microorganisms to brittleness with liquid air and then grinding them. The apparatus is described with cuts. Experiments with his serum are now being conducted on the horse.

31. **Cultivation and Biology of the Turtle Bacillus.**—The tubercle bacillus derived from a turtle has proved very effective in Friedmann's hands as a means of immunization against human and bovine tuberculosis. His interesting results were reviewed in The Journal recently, page 136. He describes experiments with it here inoculated into other cold-blooded animals. It invariably induced a rapidly fatal tuberculosis in them, but in mammals it behaved differently.

36. **Antitoxic Serums.**—Wechsberg describes the aim of serum therapy as the production of serums as polyvalent as possible, for use against the various partial toxins of the disease germs. He warns that the results of tests on animals can not always be applied to man without reserve.

37. **Open Treatment of Granulating Wounds.**—Wagner wearied of the tedious healing of granulating wounds, especially when the pyocyaneus was once installed in them. He found that patients in private practice shrink from grafting operations. For these reasons he sought for a better method of treating surface wounds after granulation was once established than the usual interminable salve treatment. He thinks the application of salves induces secretions which in turn provide a fine nest for microbes. For several years he has been treating such wounds by leaving them open to the air when the surface was covered with healthy granulations. The secretion at once diminishes, the granulations shrivel under the influence of the air, and a pellicle soon forms over the surface. If there are microbes under this pellicle retention follows, but the drying up of the wound evidently is unfavorable to the proliferation of germs. When the surroundings of the wound are healthy a granulating wound as large as the palm of the hand has frequently healed over in eight or ten days under exposure to the air. In old leg ulcers healing is less rapid, but is still very satisfactory. He has frequently treated patients who presented two or more wounds, by exposing one to the air and applying salves to the other. In every instance the superiority of the former method was unmistakably apparent. The open treatment is peculiarly effective for wounds in which grafting has been applied without much success. The unhealed flaps should be removed, and then the epidermis soon spreads from the transplanted scraps until the entire surface is covered. He thinks that the air exerts a certain stimulus on the epithelium similar to that from ether spraying. The granulations as they shrivel become flatter, which also favors the growth of epidermis. The danger of infection from the air is not so great as was formerly assumed, and granulating surfaces are particularly resistant. In years of experience he has never known a single instance of harm done by infection in these cases. Of course, he is careful not to attempt this open treatment in close contact with erysipelas or other severe infection. Its special field is in home and private practice.

39. **Adjustable Constricting Bandage.**—Spiegel's instrument is a silk webbing to form the bandage. One end terminates in a slide catch its entire width. The other end of the webbing after passing around the limb is wound on a roller projecting horizontally above the clasp device. A thumbscrew turns the roller and tightens the band as desired, after it has been clasped around the limb. It has been found a great improvement over the ordinary constricting bandage in 50 operations at Mosetig's clinic. Two cuts are given to show the simple details of the apparatus.

40. **Intracapsular Resection of the Prostate.**—In order to proceed as cautiously and with as little traumatism as possible, Rydygier makes his incision along the raphe from the root of the scrotum to near the anus, but incises the capsule 1 to 2 cm. from the median line to avoid injury of the urethra. He carefully refrains from opening into the urethra or bladder, and proceeds to intracapsular resection. The whole intervention is thus comparatively inoffensive, and if there should be recurrence of trouble, the operation could be easily repeated. He urges early intervention, before the evil results of retention have been established.

41. **Balancing Suspension Treatment of Fractures of the Humerus.**—Geissler illustrates an apparatus with which he cured a supracondylar fracture of the humerus in a boy of 7 with perfect functional results. The arm was flexed and placed in a plaster cast extending from the fingers to the upper third of the upper arm. The arm was then raised by a rope, pulley and weight, the suspension being applied a little below the elbow. The cast thus formed a right angle and the weight of the forearm just balanced the traction of the body on the upper arm. In order to make this balance perfect a weight was fastened on the cast over the hand. The elbow was thus freed from all traction. The wide band by which the arm was suspended was of adhesive plaster and passed first around the elbow before the ends were united to form the sling. The plaster cast spread the traction over the entire surface of the arm within, while the elbow was free. The bag of sand which he used for the suspension weight weighed about 6 pounds.

42. **Treatment of Congenital Dislocation of the Hip-Joint.**—Reiner has found that Schlesinger's two-time maneuver has enlarged the age limits within which bloodless reduction of the dislocation is still possible. He has thus treated 10 cases, and the results have been extremely satisfactory, although the subjects were from 10 to 15 years old, and in 2 the displacement was bilateral. The maneuver only aims to prepare the parts for the operation proper. It consists in forcing the leg into the position where the head slips most readily into its proper place, and applying a plaster cast without attempting to force the head into place. The intervention is then completed as usual, after an interval of one or two weeks. He explains the mechanism as follows: The fixation in the position secured by the first maneuver presses the head against the isthmus in such a way that it gradually stretches the muscles, and thus is removed the greatest obstacle to the final reposition of the head when the intervention is completed. Certain features of the after-treatment are important. The main point is to retain the contracture attained, leaving it to correct itself spontaneously. The active and passive exercises during the day are replaced at night by restoring the joint to the primary position. This is accomplished by a plaster bed made by molding the plaster over the child as he lies on his belly, the cast thus made including the pelvis and reaching to the top of the thorax, holding the thigh abducted at a right angle, with or without extension by means of a pad under the knee. The possibility of reproducing this primary position with ease is the best test of the perfection of the reposition. No joint can be considered faultlessly replaced which although it may allow the reproduction of the primary position yet assumes at the same time slight flexion.

43. **Permeability of Vas Deferens After Suture.**—Vulliet presents an illustration of a vas deferens in a dog sutured after resection. The cut shows the complete permeability of the vas, the epithelial lining apparently normal. He obtained this result in 3 out of 4 dogs treated by section or resection and suture of the vas deferens. The lumen is very small, but the walls are comparatively thick and allow a suture to be taken without penetrating into the lumen. He is confident that the probabilities in favor of the retained permeability of the vas in man are still more promising.

44. **Sterilization of Catgut.**—Salkindsohn remarks that catgut sterilized by Bloch's method of soaking it in a solution of 1 part iodin and 10 parts potassium iodid in 100 parts water, loses its firmness in time. Otherwise it complies with all the requirements for a perfect suture material. He thinks that this one remaining objection can be obviated by using a solution of 1 part tincture of iodin in 15 parts spirit. vini (50 per cent). This is equivalent to 2/3 per cent. iodin puri in 50 per cent. spirit. vini. The catgut is placed in this solution for a week, after which it is ready for use and can be kept indefinitely in the fluid. Thus prepared it has all the good qualities of iodized catgut, while it has the superior advantage of being durable. Catgut thus prepared a year ago is still as perfect as when first made, and he has used it for ligatures, sutures, herniotomies, etc., without finding that its age had detracted in the least from its fine qualities.

45. **Drainage of Pericardium.**—Mintz recently cured a case of suppurative pericarditis by establishing free drainage. He reached the pericardium through an incision about 7 cm. long along the lower margin of the seventh costal cartilage. The pericardium was incised over a sound inserted through an opening above, the fifth rib having been previously resected in a vain attempt to evacuate the pus. Since then he has been testing the procedure on cadavers of subjects from 9 to 70 years of age, and found that it was possible in every case to open the pericardium without injury to the pleura or peritoneum. The abdominal muscles are detached from the

rear of the left, seventh costal cartilage, reached through an oblique incision along the lower margin of the cartilage. The latter is then divided at the top and bottom of the incision, and turned back out of the way with its soft parts, including the attachment of the diaphragm. The pericardium then becomes apparent in the upper end of the wound and can be readily opened. In his experiments on the cadaver, pericardial fluid always poured out when it was incised, which demonstrates that even a small amount of exudation can be easily drained away by this technic.

49. Mountain and Sea Climate.—Loewy has been conducting comparative research on the effect of mountain and sea climate. He finds that the tests of the electrical conditions give identical results in each, and the stimulating effects on the metabolism seem to be identical in each. The rarity of the air he believes to be a minor factor in the effect of altitude, which is mainly the result of the purity of the air, its constant motion and the abrupt changes from warmth to cold, all of which may be found at the seashore. The therapeutic indications for sea or mountain climate should be well weighed. Patients already overexcited or overstimulated in any way should not be sent to the mountains or seashore. They are indicated only for cases with reserve energy, not for those in which the store of energy has to be carefully guarded. Further research is needed to determine whether the sea climate may not have the same action on the composition of the blood which is noted in the mountains. He thinks it possible that the sea climate may share this property.

50. Paranoia.—Schultze regards the paranoiac as irresponsible, even in the comparatively early stages of his disease. He is no longer master of himself, but merely the unwilling victim of his morbidly altered feelings.

51. Staphylococcus Sepsis.—A workman, 38 years old, exhibited a clinical picture which simulated that of typhoid. This presumptive diagnosis was sustained by the fact that two of his mates presented symptoms of unmistakable typhoid at about the same time. Delirium developed the thirteenth day, but all attempts to cultivate bacteria from the blood were negative. although pneumococci were found in the sputa. The fifteenth day the parotid glands swelled, and puncture revealed pure cultures of staphylococci. A similar swelling developed at the right trochanter and another at the right elbow. Death followed two days later. The patient had fallen from a ladder four weeks before his illness, striking on the right side. Slight pains were noticed in the right sacral region and right leg, and becoming worse, a physician was consulted two weeks later. He ordered dry cupping, but the patient had the parts massaged instead. The pains increased thereafter, and the symptoms simulating typhoid fever developed. The resemblance of the clinical course to that of typhoid was explained by the lesions found in the intestinal lymphatic system at the necropsy. They were almost exactly like those encountered in typhoid. The traumatism had undoubtedly induced extravasation in the right gluteus maximus. Although the injury to the skin rapidly healed, it had allowed the entrance of staphylococci and an abscess formed, too deep to be discovered by palpation, and the massage of the parts evidently drove the infectious material into the circulation, resulting in rapidly fatal general infection. The temperature showed a wider daily range than is usual in typhoid.

54. Prevention of Hay Fever.—Mohr is an enthusiastic believer in Dunbar's pollen theory of hay fever. He has been a sufferer himself for many years, and was able to confirm in his own experience all of Dunbar's assertions in regard to the cause and antipollen treatment of hay fever. Mohr has gone further, and devised a protecting device with which he has successfully warded off the irritating pollen dust, both in himself and in all others who have used the device. It is a modification of the Schmidthuisen "nostril lifter" (Nasenflügelheber), but is completed by a filtering device. It is worn inside the nose, and causes no more discomfort than the wearing of spectacles. He thinks that it has solved the problem, not only of absolute protection against hay fever, but also for trades in which there is danger of inhalation of stone dust, etc. By wearing the device a few days the sensitiveness of the mucosa was so much reduced that he could go without it for a time without inducing the previously inevitable attack of hay fever.

56. Surgery and the Medical Curriculum.—Czerny urges the appointment of school inspectors for the high schools. The students should be examined at the beginning and close of each school year to determine the influence of the sedentary life, etc. He traces the development of surgery, and shows how the field has broadened so that the training is an ever-increasing task. In order to have the student's best efforts, his heart should be in his life work, and he should select that branch for which he has an affinity and not be guided by chance. With the present modes of education, there is little chance for the students to discover these affinities, as they are tied to their books. He would restrict the number of working hours in the high schools and colleges, and give the students more time for individual initiative. They would then be able to discover their true bent, and when they reach the medical college would know the line of work in which they were most likely to excel, and would approach it as artists, not as mere breadwinners. He remarks that the world has never seen such an amount of original thinking and artistic production as in the days of ancient Greece, when the school was essentially for the development of physical strength and beauty and the minds were allowed to develop untrammeled. He thinks that twenty-six to twenty-eight hours of study during the week is the maximum that should be allowed from the standpoint of hygiene.

59. Ubiquity of Tubercle Bacilli and Disposition to Phthisis.—[Flügge is director of the Institute of Hygiene at Breslau, and it is on his announcements of the danger of infection from the droplets disseminated in coughing and speaking that some of the most important prophylactic measures are based.] He now presents arguments to prove that the tubercle bacillus is by no means ubiquitous; that it is seldom found in the dust of the street or in houses, and relates experiments and tests by various investigators to support this view. Among the latest is Praussnitz' examination of the dust from certain railway cars used exclusively for transporting tuberculous subjects. In all his tests he found tubercle bacilli only twice, and then in the sweepings. The bacilli are found only in the close proximity of tuberculous subjects—recognized or unrecognized as such—and a large number of the germs are necessary for infection of others. One investigator found it impossible to infect guinea-pigs with 40 bacilli, but they invariably contracted the infection when twice or thrice this number was used. Paper cuspidors and handkerchiefs, that can be burned, are advisable for the use of consumptives. Scraps of sputum material are liable to cling to the fingers and to the clothing, especially around the entrances to the pockets. The fingers should be frequently and thoroughly cleansed with soap and water, and the outer clothing brushed off once a month with 10 per 1,000 of bichlorid or taken to a formaldehyd disinfecting station. When the consumptive coughs he should go apart from other persons or turn his head away or hold a handkerchief before his mouth. The distance between heads in workshops should be at least one meter, thirty-nine inches, and wherever practicable, there should be partitions between employes engaged in sedentary work. In the bedroom a screen of smooth material in front of the bed is advisable if the consumptive can not have a room to himself. During the day the family should not crowd around him. During exacerbations it may be advisable to remove the consumptive to some sanitarium or convalescent home. Every child knows that phthisis is contagious, he remarks, but the measures by which the consumptive is perfectly able to protect others against infection from him are so simple and rational that their universal adoption is not an idle dream, while it would certainly be followed by a progressively diminishing number of cases of infection. He thinks that the necessity for sunny and well-ventilated dwellings is overestimated from this point of view. Sunlight will destroy the bacilli, but the consumptive is scarcely liable to spread his sputum out in a thin layer on the floor in the direct path of sunshine, and yet these are the conditions necessary for the destruction of the germs by sunlight. Particularly thorough ventilation is actually harmful as tending to disseminate the germs which otherwise are to be found only in the immediate vicinity of the subject. In regard to the predisposition to tuberculosis, he thinks our present knowledge is too limited to formulate any conclusions in regard to it. Behring's recent announcements concerning the danger of infection in the first weeks of life, summarized in THE JOURNAL, xli, page 994, are not accepted by Flügge, who points out that all children now, with the rarest exceptions, are either nursed or fed with boiled milk during early infancy. The danger from bacilli in butter is more patent, but by the time children are given butter they have outgrown the unprotected condition of early infancy on which Behring lays so much stress. Other arguments which Flügge advances against his theories are that the frequency of tuberculous infection increases with the age; that the mortality from phthisis is much greater among men than among women after the age of 20; the prevalence of phthisis among those employed in certain industries; the observations of phthisis unmistakably acquired late in life, and of cases among persons who were never fed on cow's milk during infancy; also the fact that in regions where infants are breast fed the number of cases of tuberculosis is not materially lower than in other regions where artificial feeding is almost universal. As a concluding argument, he refers to the prevalence of tuberculosis in countries where there are no cattle or where milk is not used as an article of food to any extent. Behring overlooks the fact that infantile gastrointestinal disturbances following the use of milk are restricted to the three summer months and parallel the excessive heat. In countries in which the summers are cool they do not occur at all. During the nine other months of the year there is not the same difficulty in keeping the milk cool and in good condition. Physicians most experienced in children's diseases have never observed any injurious effects on normal children from milk briefly boiled. The German law forbids under penalty the addition of any chemical to milk, and to repeal this law in order to introduce Behring's method of formalinizing the milk seems unjustified at present. In regard to sterilization of butter, Flügge's research has shown that pasteurization of the cream would not interfere in any way with the production of butter, in case such a measure were deemed advisable.

60. **Active Immunization Against Tuberculosis.**—Friedmann's successful immunization of animals against tuberculosis has already been mentioned in these columns, page 136. He used for the purpose bacilli cultivated from the turtle, and thinks that these cultures combine all the requisites needed for successful immunization of mammals, as he enumerates in detail. He compares his technic and results with those published recently by Moeller in the *Ztft. f. Tub. und Heilstättenwesen*, V. 3. The latter used bacilli derived likewise from a cold-blooded animal, the blind-worm. The bacilli derived from this reptile, however, do not possess all the attributes which Friedmann regards as indispensable. Moeller experimented on himself, making three intravenous injections of living bacilli from the blind-worm cultures. After this preliminary treatment, he inoculated himself with 1/50 of a loop of human bacilli, but Friedmann does not regard these subsequent tests as conclusive, owing to the early death of the control guinea-pigs. [Friedmann's turtle experiments have attracted wide attention in other countries, although the German word for his culture—"Schildkrötentuberkelbazillenstamm"—has caused some amusement.—ED.]

62. **Podophyllin in Ankylostomiasis.**—Neumann reports experiences and experiments which have established that podophyllin has a specific action on the epithelium of the intestines which interferes with the parasites' clinging to it. They are thus easily dislodged by male fern after administration of podophyllin or the latter alone may be sufficient to dislodge and expel them. Its action is much more pronounced than that of calomel, while it is a much safer drug than the latter for this purpose.

71. **Lead Pipes and Drinking Water.**—Sanchez y Rubio asserts that the notion that water distributed through lead pipes is harmful is based on an unreasonable prejudice. In an address at the Egyptian Medical Congress he stated that a large part of the drinking water of Madrid is distributed by means of lead pipes, and yet tests conducted through two years have failed to disclose any traces of lead in the water drawn from them. No diseases nor affections have been known that could be attributed to lead poisoning.

77 Acute Septic Colitis Due to Milk Poisoning. G. F. Vincent.
78 *Note on the Nature of the Parasitic Bodies Found in Tropical Splenomegaly. W. B. Leishman.

74. **Aseptic Surgery.**—The difficulties and inconsistencies of aseptic surgery as it is practiced are shown by Lockwood, who can not see how we are ever to dispense with chemical antisepsis. No condition or apparatus can ensure an absolutely aseptic atmosphere, but he thinks it irrational to make no attempt to rid the air of bacteria. The better the ideal the better the success. Different kinds of infection ought to be fought with different kinds of chemicals used in different ways. Experience has a great deal to teach in this respect. In hospital work each surgeon should have his own wards, theaters, instruments, nurses and assistants, and the septic and aseptic wards should be separate. More isolation wards are required. The present system of assistants necessarily increases the amount of sepsis, but he says there is some difficulty in saying which is best, a system which sends out into the world numbers

of men well educated as to the requirements of aseptic surgery or one which helps one surgeon to obtain the minimum percentage of suppuration. The answer, he thinks, is clear; the greatest good to the greatest number must prevail. Each unnecessary pair of hands should be eliminated. The surgeon should alone handle the ligatures, instruments, sutures and dressings. The single assistant has little to do, and his fingers ought to be kept out of the wound. A garrulous assistant is particularly bad. The instruments should be few and simple and the material uniform; a diversity of material multiplies the chances of infection.

75. **Appendicitis.**—Spanton reports a number of cases illustrating some of the difficulties of diagnosis. The more he sees of appendicitis the more he is convinced that it is safer to operate too soon than to delay too long. No time should be lost when the symptoms of general peritonitis appear. When the appendix can be safely removed, he always removes it, but in all instances free drainage may stave off imminent death when it is not possible to do more.

76. **Cancer.**—Power has tried Otto Schmidt's serum derived from a parasite cultivated from cancer growths, in the treatment of several cases of tumor with unsatisfactory results. He finds a reaction after the injection and an inflammation in the growths, but he can not satisfy himself that the serum acted by selection on malignant tissues only. It seemed only to intensify the pre-existing inflammation. It is painful, and the disease progresses, even to a fatal issue, while the injections are being given. He can say nothing specially favorable of the method either from a prophylactic, diagnostic or curative standpoint. Still further observations may be desirable as his tests of three cases were somewhat limited. One was not suffering from cancer, but from a non-malignant growth.

78. **Leishman-Donovan Bodies.**—Leishman points out the close resemblance of these bodies to some described by Dr J. H. Wright (*Jour. Med. Research*, December) from a case of tropical ulcer. Wright considered these parasitic, and proposed a new genus and species under the name of *Helcosoma tropicum.* Major Ronald Ross frequently has found in the pus of Delhi boils large numbers of a flagellated organism, the *Cercomonas hominis.* Leishman says that it is just possible that Wright's parasites may be altered cercomonads. The frequency of Delhi sores in India offers ample means for confirming Wright's observations. Leishman thinks that Laveran's view—that these parasites are a new species of *Piroplasma*—seems to be contraindicated.

87 Case of Ovarian "Fibroid" Tumor Removed by Posterior Colpotomy; Subsequent Pregnancy. John Phillips.

79. **Snake Venoms.**—Rogers has studied the various forms of snake venom, both colubrine and viperine types, and describes their respective actions and peculiarities. In the colubrine type the tendency seems to be to a paralysis of the respiration and end plates of the phrenic nerves, while the hemolysis is slight. The viperine venom produces a paralysis of the vasomotor center with marked hemolysis, as well as noncoagulation of the blood. One colubrine form—Bungarus fasciatus, the banded krait—has a viperine action on the vasomotor center, and this is emphasized by failure of Calmette's serum to counteract its effects. The most powerful poisons seem to be those of the sea snakes and cobras. In most all of these, with the one exception, Calmette's serum had effect. It should be used in every case of colubrine poisoning. He thinks a more generally powerful antitoxin can be prepared by using in this preparation a mixture of the different purely colubrine venoms. Artificial respiration may also be of use; one case is on record in which life apparently was saved by it. In viperine venoms, on the other hand, the Calmette serum has little or no effect. Rogers finds that 0.1 to 0.5 c.c. of a 1 in 1,000 solution of adrenal chlorid immediately sends up the blood pressure in cats after viper poisoning, but it is not entirely effective. He thinks that it, as well as nicotin, may have some value; the latter also stimulates the flagging respiratory center and restores the blood pressure. The venoms of vipers are much weaker than those of the colubrine species, and this is in favor of the remedies. In conclusion, he recommends destroying all snake venoms at the point of inoculation by permanganate of potash. Of course, this will not be effective if the venom is allowed to circulate, which it does with great rapidity, but the use of a ligature around the part greatly increases its efficacy. He advises the use of pure crystals of the permanganate of potash rubbed well into the wound. At the suggestion of Sir Lauder Brunton, an instrument has been made consisting of a lancet covered with a sheath, with a receptacle at its base, in which permanganate crystals are kept. This instrument can be carried in the waistcoat pocket for instant use, and can be sold at a very low figure. He thinks his results warrant the use of this method in practice, especially as it affects the venom of all snakes.

82. **Gastric Adhesions.**—In 5 per cent. of postmortems, according to the records, evidence of present or ancient gastric ulcer is found. In 40 per cent. of such cases, according to Fenwick, there are adhesions. If careful examination is made, Paton estimates that adhesions will be found in the gastric region in about 2 per cent. of all postmortems. These may be due to stomach ulcer, gallstones, trauma, pancreatic disease, tubercle, syphilis, etc., but the only common causes are gastric and duodenal ulcer or disease of the bile passages. In 123 cases, Fenwick found adhesions to the pancreas, liver, or to both in 92, in the remaining 31 cases the stomach was attached to the colon, mesentery, liver or spleen, or to three or more organs. Adhesions to the anterior wall seem to have been absent. The situation is of importance, as the usual attachment is to one or more mobile organs which are liable to be dragged on. The adhesion may be close, broad or long and slender. A very unusual variety is that which occasionally occurs to the anterior abdominal wall, forming with the infiltrated stomach wall and the thickened abdominal parietes a tumor, which may be easily mistaken for a new growth. Such cases of plastic perigastritis have been recorded by Billroth, Mikulicz and Mayo Robson. Such extensive adhesions may have been caused by local gastric perforation. The effect of these adhesions may be to distort or constrict the stomach or to interfere with its motility and contraction, as well as to involve other organs like the gall bladder, causing jaundice, etc. Pain and tenderness are the principal symptoms. Physical examination as a rule reveals nothing beyond tenderness, and there may be an increase in the size of the stomach. The appearance of the tumor may suggest malignancy, but the long continuance of the illness without serious interference with the general health will be against this. Exertion seems to bring on pain and change of position may relieve it. The ingestion of food may have no effect whatever. Paton reports many cases. He recommends verifying the diagnosis by exploratory incision; this should be recommended to patients after a fair trial of dietetic, medicinal and general hygienic measures has failed. If adhesions are found, they should be separated or divided. To prevent adhesions reforming, he believes aseptic methods best, but no antiseptics should be used within the abdominal cavity. If any fluid is used, it should be sterile saline solution. Vogel has found that greater freedom of movement than is usual after abdominal operations is also useful in preventing adhesions, as well as mild laxatives and the use of atropin, salicylate, general massage, etc. In preventing peristalsis and where adhesions can not be separated, and it is certain that reformation would occur and the trouble seems due to interference with the stomach emptying itself, pyloroplasty

and gastrojejunostomy are valuable. The latter is usually the better.

Journal of Tropical Medicine, London.

88 Appendicitis in the China Fleet. F. H. A. Clayton.
89 *Scarlet Fever in Natives of India. Wm. Robertson.
90 *Adrenalin Chlorid in Plague and Other Diseases. K. C. Bose.
91 Case of Spirillum Fever. Leopold G. Hill.

89. **Scarlet Fever.**—The immunity of natives of India to scarlet fever seems to be subject to some exceptions, as Robertson reports an epidemic of some thirty cases, with three deaths. He finds that the disease, as a rule, takes a milder course. It seems to spread with rapidity among the Indian children, and a larger proportion of adults take it than is usual in the white race. He thinks the skin of the Indian native does not permit of the profuse development of the toxins, hence grave forms of the affection do not occur. The fact that the native nasopharynx is healthier than that of the whites, as a rule, may account for a part of the resistance to the germ.

90. **Adrenalin in Plague.**—Bose reports 24 cases of plague, with 11 deaths, all treated by adrenalin in 1, 2 and even 3 drop doses internally each hour. He thinks there can be no doubt that adrenalin is a remedy safely to be tried in plague. He has treated over 60 cases by this method, and with results in no way unfavorable. In all stages of the disease it kept the pulse up well and brought down the temperature and seemed to relieve the maniacal delirium. Its tonic action on the heart is its best recommendation. No case in which this remedy was freely used died from interstitial hemorrhage. Its effect, however, on intestinal and pneumonic plague was not encouraging, for out of a good number of such cases, only 2 recovered. In bubonic plague, uncomplicated with lung and intestinal troubles, he thinks it is a sovereign remedy. He speaks highly of its value in typhoid, malarial spleen and in surgical practice.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

Liverpool School of Tropical Medicine—Memoirs—Report on Malaria at Ismailia and Suez. *By Ronald Ross, F.R.C.S.,* D.P.H., F.R.S., C.B. Paper. Pp. 24. Price, 36 cents. Report on the Sanitary Conditions of Cape Coast Town, with Suggestion as to Improvement of Same. 1902. By Dr. M. Logan Taylor, M.B., Ch.B. Price, 36 cents. Infant Feeding in Its Relation to Health and Disease. A Modern Book on All Methods of Feeding. For Students, Practitioners and Nurses. By Louis Fischer, M.D., Visiting Physician to the Willard Parker and Riverside Hospitals of New York City. Third Edition, Thoroughly Revised and Largely Rewritten. Containing 54 Illustrations, with 24 Charts and Tables, Mostly Original. Cloth. Pp. 357. Price, $1.50 net. Philadelphia: F. A. Davis.

What Shall We Eat? The Food Question from the Standpoint of Health, Strength and Economy. Containing Numerous Tables, Showing the Constituent Elements of Over Three Hundred Food Products, and Their Relations, Cost and Nutritious Values, Time of Digestion, etc., Indicating Best Foods for All Classes and Conditions. By Alfred Andrews. Pp. 116. Price, 75 cents. New York: Health Culture Co.

A Manual of Medicine. Edited by W. H. Allchin, M.D., Lond., F.R.C.P., F.R.S. Ed., Senior Physician and Lecturer on Clinical Medicine, Westminster Hospital. Vol. V. Diseases of the Digestive System and of the Liver, Diseases of the Peritoneum and of the Vessels of the Abdomen, Diseases of the Kidneys, Diseases of the Ductless Glands. Cloth. Pp. 687. Price, $2.00. New York: The Macmillan Co. 1904.

A Handbook of Ophthalmic Science and Practice. For Students and Practitioners. By Henry E. Juler, F.R.C.S., Ophthalmic Surgeon to St. Mary's Hospital. Third Edition, Revised and Enlarged. With 190 Illustrations and 25 Full-page Plates in Colors and Black. Cloth. Pp. 733. Price, $5.25 net. Philadelphia and New York: Lea Brothers & Co. 1904.

Transactions of the New York Academy of Medicine, 1896-1901. Semi-centennial Celebration. Anniversary Discourses, Presidential Addresses, Memorial Addresses, Wesley M. Carpenter Lectures, List of Papers Read at the State Meetings of the Academy, Officers of the Academy and of the Sections. Paper, Pp. 471. Printed for the Academy. 1903.

Howe's Handbook of Parliamentary Usage. Arranged for the Instant Use of Legislative and Mass Meetings, Clubs and Fraternal Orders, Teachers, Students, Workingmen, and All Who Desire to Conduct Themselves "Decently and in Order" in Public Assemblies. By Frank William Howe. Cloth. Pp. 54. Price, 50 cents postpaid. New York: Hinds and Noble.

Biographic Clinics. Volume II. The Origin of the Ill Health of George Eliot, George Henry Lewes, Wagner, Parkman, Jane Welch Carlyle, Spencer, Whittier, Margaret Fuller Ossoli and Nietzsche. By George M. Gould, M.D., Editor of American Medicine. Cloth. Pp. 392. Price, $1.00. Philadelphia: P. Blakiston's Son & Co. 1904.

A Manual of General or Experimental Pathology, for Students and Practitioners. By Walter Sydney Lazarus-Barlow, B.A., B.C., M.D., F.R.C.P., Director of the Cancer Research Laboratories of the Middlesex Hospital. Second Edition. Cloth. Pp. 736. Price, $6.50 net. Philadelphia: P. Blakiston's Son & Co. 1904.

Department of the Interior. Bureau of Government Laboratories. Serum Laboratory. Preliminary Report on the Study of Rinderpest of Cattle and *Carabaos in the Philippine Islands.* By James W. Jobling, M.D., Director of the Serum Laboratory. Paper. Pp. 22. Manila: Bureau of Public Printing. 1903.

Diseases of the Eye. By L. Webster Fox, A.M., M.D., Professor of Ophthalmology in the Medico-Chirurgical College of Philadelphia. With Five Colored Plates and 296 Illustrations in the Text. Cloth. Pp. 584. Price $4.00. New York and London: D. Appleton & Co. 1904.

Eighth Annual Report of the Board of Managers of the Springfield State Hospital *of the State of Maryland,* Sykesville, Md. To His Excellency, the Governor of Maryland. Oct. 1, 1903. Paper. Pp. 52. Baltimore: Sun Book and Job Printing Office. 1904.

Rabies, Its Place Among Germ Diseases and Its Origin in the Animal Kingdom. By David Sime, M.D. Cloth. Pp. 290. Price, 10/6 net. Cambridge: University Press. 1903. New York: The Macmillan Co.

Memoria de Los Trabajos Ejecutados por el Consejo Superior de Salubridad, En El Ano de 1900. Paper. Pp. 184. Mexico: *Imprenta del Gobierno en el Ex.* 1902.

A Chart of Diseases of the Lungs, Pleurae, Bronchi, Trachea and Larynx. Paper. Published by the McArthur Hypophosphite Co., Ansonia, Conn.

Report of the Trustees of Bellevue and Allied Hospitals for Quarter Ending Sept. 30, 1903. Paper. Pp. 22. New York: Mail and Express Co. 1903.

The Ideal City. By Cosimo Noto, M.D. Cloth. Pp. 377. New York: New York Labor News Company. 1903.

Medical and Surgical Report of St. Luke's Hospital, Year Ending Sept. 30, 1903. Paper. Pp. 104.

New Patents.

Patents of Jan. 19 to Feb. 9 of interest to physicians:

750237. Iris-diaphragm. Edward Bausch and G. Hommel, Rochester, N. Y.
749811. *Surgical retainer. Augustus C. Bernays, St. Louis.*
750048. Casein compound and producing same. Hezekiah K. Brooks, Bellows Falls, Vt.
749813. Portable *x*-ray apparatus. Eugene W. Caldwell, New York.
750099. Ophthalmoscope. Henry L. De Zeng, Philadelphia, and P. S. Reid, Hammonton, N. J.
750103. Bedpan. Anton C. *Eggers,* New York.
750104. Throat bag. Anton C. Eggers, New York.
749963. Apparatus for applying disinfectants to water closets. George S. Gallagher, New York.
749728. Water purifying apparatus. John C. W. Greth, Pittsburg, Pa.
749731. Stretcher stand. Harry C. Hall, Telluride, Colo.
749934. Ligature tube. Bertram K. Hollister, Chicago.
749874. Coin-controlled atomizer. Wm. C. Meyer, St. Louis.
750568. Massage implement. James Barker, Philadelphia.
750521. Atomizer. Forrest V. Brayer, Blooming Valley, Pa.
750584. Administering electrical vibrations. Fred H. Brown, Los Angeles, Cal.
750347. Apparatus for disinfecting paper money. Charles B. Clark, *Buffalo.*
750260. Atomizer. Frank B. Comins, Sharon, Mass.
750625. Ear-drum protector. James A. R. Elliott, Kansas City, Mo.
750276. Vaginal syringe. Francis J. Gruss, San Francisco.
750465. Surgical instrument case. Frederick A. Koch, New York.
750297. Nasal douche. Fred W. Moffitt, Chicago.
750711. Optical device. Michael F. Shea, Newport, R. I.
750735. Implement for mechanical vibratory *treatment, Fenton* B. Turck, Chicago.
750515. Paraffin-bath for microscopists. Frederick A. Wunderlich, New York.
751266. Pocket spittoon. Joseph M. A. Deydier, Lyons, France
750832. Preparing food casein. Andrew A. Dunham, New York.
751167. Surgical chair. Aaron P. Gould, Canton, Ohio.
750983. Abdominal belt. Arthur B. Kendrick, Philadelphia.
750878. Vaginal syringe. Orville P. Moon, Lorain, Ohio.
751415. Nipple shield. Frank P. Prindle, Stamford, Conn.
751031. Massaging implement. Julius B. Wantz, Chicago.
751475. Speculum. Thomas De Vilbiss, Toledo, Ohio.
751513. Surgical instrument. Lyman C. Holbrook, Charlotte, Mich.
751942. Crutch. John A. Renno, Sumter, S. C.
751886. Apparatus for sterilizing water. Henry J. Wessels, Paris, France.

VOL. XLII. CHICAGO, ILLINOIS, MARCH 5, 1904. No. 10.

Address.

THE PRESENT STATUS OF THE MEDICAL EXPERT.*

ALGERNON T. BRISTOW, M.D.
BROOKLYN, N. Y.

Our present system of jurisprudence dates from a remote past. It has replaced the personal method of settling disputes and its later phase, trial by battle. Founded at a time when the national life was simple and civilization just beginning to displace the barbarism of the dark ages, it has, nevertheless, shown a remarkable elasticity in adapting itself to the changing conditions and increased complexity of a rapidly developing and maturer age.

To reason, however, that because our present system has endured for centuries therefore it should never be either changed or modified, does not seem good logic, nor is the incapacity to change a mark of excellence or perfection. "God alone knows what a petit jury will do" is an adage with which lawyers are not unfamiliar. That such a saying should have become proverbial is certainly not evidence that the present system is without its faults or shortcomings. The more than occasional vagaries of our petit juries arise from the fact that many cases now tried in the courts require of the jury more than a common-school education and ordinary intelligence to unravel the tangle of conflicting and often technical evidence and render a verdict which shall be in accordance with the actual facts. A hundred years ago there was little machinery in use, and the craftsman was in reality engaged in a handicraft, but at present the skilled craftsman of the earlier days of the republic has been replaced by an individual who is now nothing more than the tender of a piece of machinery. The problems of those times were those whose details were familiar to the juryman, because they were part of his daily life, or of such simple complexion as to be of easy comprehension. "Jurors reached their conclusions for the most part from personal knowledge already possessed." (Hist. Eng. Law, 2 Pollock-Maitland, 619-625.) The juries of that time were thus enabled to render verdicts which left little to be desired. To-day the circumstances which surround a jury are entirely different. Every decade adds new complexities to our civilization, and new perplexities to the ordinary juryman. He is often expected to unravel masses of technical evidence on subjects of which he is totally ignorant, to reconcile the evidence of warring experts and render a verdict according to the evidence. Is it any wonder that our present system sometimes shows signs of being overtaxed—in need of some modification or addition? Is it strange that a system that was quite adequate to the needs of a community which existed two centuries ago, should now show signs of inadequacy and incompleteness? Our national life has greatly changed and broadened, but our legal machinery has remained substantially the same. Nevertheless, the medical profession has found the lawyers perfectly willing to make proverbs concerning the uncertainties of a time-honored system, yet singularly conservative and unwilling to acknowledge it in need of amendment. This is partly due, no doubt, to the fact that our law is so largely made up of precedent. The courts of to-day are bound by the decisions of the courts of the past, whose decisions stand but whose judges are with the dust. There is good reason for conservatism in legal practice, but a precedent which has only the lapse of time in its favor is better honored in the breach than the observance, particularly where experience shows that it is the cause of frequent injustice when blindly followed, simply because it is precedent and so time honored.

To the medical profession there is no part of the administration of justice so important and of such interest as that which deals with medical expert evidence. Whatever else may be inefficient or defective in our present jury system, it is the present method of securing and presenting medical testimony to the jury that grieves and injures us.

The public judges any class of men according to their appearance in public; and, although our public functions are but incidents in our lives, merely occasional, unlike our confrères of the law and ministry, nevertheless the people continue to judge us according to our appearance when summoned to the courts to testify. In a recent article on expert testimony, Judge Woodward says of a prominent surgeon in this state, that he was asked the following question by the counsel for the prisoner: "Isn't it fair to assume if I had money to pay the physicians for their time that I could step out here in the city and secure half a dozen competent physicians who, in answer to the hypothetical question put by the district attorney, would give me exactly the opposite answer?" The witness replied: "I think it is." A survey of all the celebrated criminal cases of the past twenty-five years in which medical expert testimony has figured, would give ample proof of the truth of this answer. The record of the medical testimony in the countless damage suits which blockade the calendars of our courts would confirm it. Is it strange that the medical profession should occupy a lower plane in the public estimation than it deserves? It is unfortunately true that the testimony of the medical expert as at present procured and elicited in our courts, is utterly untrustworthy, and has brought unmerited disgrace and contumely on a body of worthy and self-sacrificing men. In the same article occur the following quotations from judicial opinions: From an opinion by Judge Goodrich: "Paid experts, swearing for or against the sanity of a prisoner, according to the amount of the fee and the person who calls them." Judge Rumsey: "The sole difference between the expert and an advocate being that he makes his argument under oath and that he endeavors to add the weight of the oath to the opinion of the advocate." Judge Adams of Canandaigua: "Expert witnesses are far more anxious to destroy each other . . . than to elucidate the particular question in issue."

---

* Anniversary address by the president before the ninety-eighth annual session of the Medical Society of the State of New York, Albany.

These denunciations from the bench do not lack vigor. Is it then true that, in spite of the solemnity of our Hippocratic oath, our professed altruism, our unending record of charitable deeds. our high-minded codes of ethics, that we are, after all, but a set of hypocrites? Can an entire profession be so given over to the devil and his works as to deserve such denunciations? Are our ranks filled with liars and perjurers? Is it true that all the really good men follow the profession of the law, and do none of them by any chance filter into medicine? Let some psychologist or disciple of Lombroso scan the faces in this or any other assemblage of medical men and tell us whether we bear the stigmata of degeneracy, and are unable to tell the truth under oath if there is a dollar in telling a lie. On the contrary, the profession of medicine has ever been consecrated to the public service. When pestilence walked abroad in our land and its victims were falling on every side, struck down by the invisible arrows of death, then have legislatures adjourned in panic; judges, lawyers and clients fled from the courthouse until a more convenient season, but the physicians stayed behind. Had they some shield to interpose between their defenseless breasts and the darts of the unseen foe? No, they had no other shield save that which every brave man carries—an invincible determination, the inability to acknowledge fear, an overpowering sense of duty—and they interposed their own bodies between a stricken people and the midnight wrath, and fell by the wayside together with those they strove to save.

While this century was still in its swaddling clothes, in order to solve the mystery of the yellow death, men of our profession sought out and courted danger that they might rob the grim spectre of his mystery and his quiver of its most poisoned arrow. The members of the United States Army Yellow Fever Commission, who suffered themselves to be inoculated with the most dreaded of scourges, were just as truly the leaders of a forlorn hope as the uniformed band that storms a dangerous breach. Dr. Lazear died that others might live. He is not alone in his martyrdom, but stands enshrined in our hearts, the type of many who have gone before, and countless willing sacrifices that are to come. Such deeds as these have ever been the history of our profession. Is it possible, then, for virtue and mendacity to go hand in hand? Is an unselfish devotion to duty the twin brother of shameless greed? Says an ancient and sacred volume: "Do men gather grapes of thorns, or figs of thistles?" If medical expert testimony is at present without value, is it not reasonable to look for the cause of the defect elsewhere than in the personal character of the physicians or a faulty standard of professional morals? No one will contend that the men in our profession are less worthy of confidence in other respects than other classes of individuals, and, whatever may have been our differences with respect to codes of ethics, they have never been along the line of a lowered standard of truthfulness.

There must, therefore, be some other cause for the present untrustworthiness of the medical witness, and if it is not in the individual nor in the professional standard, the courts and the public must look elsewhere for the defect; and, what is of far more importance, be willing to correct it when found. Judge Endlich of Pennsylvania says (Am. Law Rev. 32-851): "It is not expert testimony that is at fault; it is in our way of handling it." In Griggs vs. The Lake Clear Water Company (40 Cal., p. 405), the justice who presided at the trial of the cause wrote as follows: "Even men of the highest character and integrity are apt to be prejudiced in favor of the party by whom they are employed, and as a matter of fact, no expert is called until the party calling him is assured that his opinion will be favorable." Says an English authority, Lord Campbell: "Skilled witnesses come with such a bias on their minds . . . that hardly any weight should be given to their evidence." In an action for a dissolution of partnership, one of the parties employed an expert to examine the books and sought to have the expenses taxed on the losing party. In refusing, the court said: "If the services of an expert are necessary for the proper presentation and determination of the case, he should be appointed by the court. When he is in the employ of one of the parties, the temptation to act in the interest of such party is apparent. Therefore, in order to secure his fair and disinterested services, he should be appointed by the court and not by either of the parties." Another opinion from the Supreme Court is as follows: "Expert witnesses ought to be selected by the court, and should be impartial as well as skillful and learned." Then follows the remarkable statement: "A contrary practice is now probably too well established to allow the more salutary rule to prevail."

This admission is an aspersion on both the bar and the legislature. A judge on the bench admits the breakdown of the system, but feebly exclaims that it has been too long established to be changed. If the lawyers are proud of that admission, let them make the most of it. Says Judge Woodward in the article before quoted, poking fun at the doctors: "The medical expert of to-day would laugh at the opinion of the medical expert of 1678 and 1679. . . . A hundred years from now medical men will, no doubt, laugh at the medical opinion of 1902." If the learned justice had said that the medical expert of to-day disagrees with some of the opinions held 200 years ago, his logic would have been more exact. I would like, however, in view of the above plaintive excuse for the retaining of a bad system, to call Judge Woodward's attention to his statement that physicians are quite willing to change a theory or practice in their own profession when experience has proved it erroneous or bad. They certainly do not insist on retaining it on the plea that "we have had it so long, you know."

Stability and permanence are in themselves highly desirable in any legal system. Constant changes in our rules of procedure would result in confusion and uncertainty, a condition of affairs intolerable in legal practice. To assume, on the contrary, that rules of procedure should never change, would give an authority and weight to precedent which ought not to prevail in the face of a proved necessity or desirability for change. Many great changes have already been made in our law, as, for example, in the law of evidence. Says Professor Robertson in his article on law in the Encyclopedia Britannica: "It (the law of evidence) has been almost wholly transformed by direct legislative enactment, act after act having been passed as occasion pointed out defects in what had already been accomplished." Under proper circumstances, then, in so conservative a land as Great Britain, the rules of evidence have been modified and amended to conform to the changing spirit of the times and the larger development of the national life. It does not appear that these changes, important and radical as they must have been to justify Professor Robertson's phrase "wholly transformed," have resulted in disaster to the British system of jurisprudence. It is possible, therefore, to bring about reformation in the long-established laws of a great state without wreck or wrong. That a change in the present system of selecting and presenting medical expert evidence is desirable, seems to be admitted by some very eminent jurists, although the opinions are not unanimous. Sir James Stephens expresses it as his opinion that the present system is perfect and in need of no change. An echo of this opinion is heard in Judge Woodward's article, in which he says: "I do not believe that the fault is in the system." It will be seen, therefore, that great legal experts differ on important questions of opinion as well as great medical experts, although to read the caustic remarks emanating from the bench, we are led to believe that physicians always disagree, jurists never.

It will be agreed that consistency in the law is just as important and desirable as permanence, yet we do not find either entire consistency or strict logic when we inquire of the law as to what constitutes an expert. Thus, in an opinion before quoted, the judge said of the expert that he should be learned as well as skillful. So, too, Chief Justice Shaw of Massachusetts says: "An expert is a person of large experience in any particular department of art, business or science. . . . It is because a man's professional pursuits—his peculiar skill and knowledge—enable him to draw an inference where men of common experience would be in doubt, that his opinion is admissible." But in Hathaway vs. National Life Insurance Company (48 Vt., p. 335, et seq.), the judge said: "A general practitioner is a competent witness. The law does not require the medical witness to have made a specialty of the subject to testify in relation to the same." It has even been held that a lawyer was a competent medical expert, who, sixteen years before, had attended a course of medical lectures, obtained a license from the state to practice, had practiced for one year, and then abandoned medicine for law, which he had been practicing during the interval. It is doubtful whether this lawyer-doctor or doctor-lawyer, declared by another lawyer as competent to give expert medical evidence, could have even described the circulation of the blood. In ludicrous contrast to this opinion is that of the judge in McEwen vs. Bigelow (40 Mich., 215), in which it was held of a plumber who had been out of business for twenty years, that "this was a long time to be out of a business that must have changed so greatly in that time," and he was held not to be entitled to give expert testimony. The trouble with the plumber, evidently, was that he had not become a lawyer, in which case the views of a sympathetic court might have been those of the California judge just cited. It is not quite clear, says Rogers, whether a man must have been engaged in active practice at all. There is an Alabama decision that it is not necessary. This decision is supported by the opinion of Redfield (Greenfield on Evidence), "but generally nothing more is required to entitle one to give testimony as an expert than that he has been educated in the particular art or profession." Thus a stripling, who has just gained his degree, is put on the same footing, so far as his right to give expert testimony is concerned, with a man of experience and distinguished attainment. The jury is left to decide on the relative weight which is to be given to the opinion of an impudent ignoramus and the learned and skillful expert described in another opinion. As an example of the evils of such a system, the following, which came under the observation of the writer, may serve: A man received a simple fracture of the lower end of the tibia in January, and was discharged from the hospital in February, with the fracture united, but with the slight edema that is usual in such cases after the removal of the plaster-of-paris splint. There was never even any pretense that suppuration had been present, as the fracture was simple. In May, the man contracted a lobar pneumonia, from which he died. His widow brought suit on the ground that the fracture was the cause of the pneumonia. The medical witness for the plaintiff, I will not call him an expert, testified that the pneumonia was of septic origin and due to the fracture. In vain two professors, one of clinical medicine and the other of surgery, testified that this was an impossibility, and that the patient died of a lobar pneumonia which bore no relation whatever to the fracture incurred five months previous. The intelligent jury gave the plaintiff a verdict, which, I am happy to say, was afterward reversed. Such a blunder was rendered possible by the loose and contradictory definitions of what constitutes an expert.

It is perverse logic which declares that a man who has the technical education of three or four years in a medical school is on a par in respect to his ability to give expert evidence with a man of the same education, but added years of experience and observation. Let us apply the same reasoning to the sister profession. On a complicated and doubtful question of law, what weight would the learned author of this remarkable opinion be willing to give a man who had studied law for a term in a law school, then abandoned law for medicine after a brief further experience of a year's practice, and, after sixteen years' interval, sought to be admitted as a legal expert, a veritable Daniel come to judgment? I doubt whether the learned justice would be likely to seek such aid in writing an opinion on a doubtful point. If this appears an absurdity when applied to the law, why is it any the less an absurdity when applied to medicine? Is medicine, then, so simple and law so much more profound, not to speak of the Michigan plumber? To the lay mind, a review of these conflicting decisions brings the conviction that there is too little certainty among the bench and bar as to the qualifications necessary to constitute a witness an expert. Still more anomalous becomes the position of the bench in the light of the following objection, which has been made by an eminent jurist, to the proposal that there should be a state board of experts. He says: "Men eminent in one branch of their profession often have a superficial knowledge of the other branches, so if all questions of medical science had to be referred to a board of government experts, suitors would be practically prohibited from availing themselves of other experts qualified by their special knowledge on that particular subject to form an accurate opinion." Nevertheless, all the decisions cited clearly permit incompetent men to testify, the only qualification apparently being that they shall have a degree in medicine and agree with the theory of the case held by the side that calls them. This is certainly very convenient for the suitors, but whether it is conducive to impartial opinions may well be doubted. Is it strange that a system which starts in confusion should end in chaos?

The function of the expert is very similar to that of the jury. He is usually called on to give an opinion on certain statements of fact generally placed before him in the form of a hypothetical question. Unlike the jury, however, he is not permitted to question these facts nor to pass on them. He is asked to assume their truth, and is then required to give his *opinion*, his verdict, if you please. Let us for the moment pass from the consideration of the expert to a brief consideration of that bulwark of Anglo-Saxon liberty, the jury, for ages the protector of the rights of the humblest citizen, which also renders an opinion on the facts brought out at the trial of the cause. The jury is a body of twelve men called from all walks of life to listen to the evidence, to give its just value so far as this is possible to finite minds, and render a verdict which shall be just. Court's and advocates, particularly in criminal cases involving the capital penalty and not seldom in important civil cases, spend much time in securing twelve men from a panel of hundreds of citizens who have shown themselves after the most severe cross-examination to be unprejudiced and beyond the possibility of bias. Frequently weeks have been spent in securing a jury, particularly in cases which have excited much public attention. This is a notorious fact, and adds thousands of dollars to the expense of the trial. Let us suppose that a contrary course was pursued, and the district attorney was permitted to name six men whom he had previously interviewed to his satisfacton, and that a similar privilege was given to the counsel for the prisoner to select in similar fashion six other jurymen, on the trial of the case what would be the prospect of an agreement? Fortunately for the administration of justice, our jurymen must still pass through a three-fold sieve before they are sworn in and admitted to the jury box. Before the jury thus carefully selected, each of the contending parties now summons expert witnesses who are to give their opinion on certain facts or alleged facts. It is just as important that they shall be free from bias as the members of the jury, for their function is very similar, yet precisely that manner of selecting them is used which seems monstrous when even mentioned in connection with the jury box. Says Judge Miller of the United States Supreme Court: "Skilled witnesses are required to speak not to facts but to opinions, *and it is* surprising with what facility their views can be made to correspond with the wishes or interests of those who call them." But why should it be surprising? The lawyers have chosen their witnesses on *ex parte* statements. Also Lord Campbell says: "Skilled witnesses come with such a bias on their minds that hardly any weight should be given to their evidence." Each of these utterances goes right to the heart of the evil, but blames the witnesses and passes by without a word of disapproval the system which is entirely responsible for the fact of bias, which is, after all, the charge against the expert. While opposing counsel are allowed to employ their own experts without restriction—in short, to go shopping until they match the color of their own case—so long will the courts be compelled to endure the evil which their complaints accentuate but will not remove. Can the bench expect that lawyers who are permitted to secure their own experts are going to summon men whose views contravene their wishes or the interests of their clients? The system is as essentially vicious applied to the opinion-testimony of the medical expert as it would be if applied to the jurymen whose verdict is to set the prisoner free or bend his neck under the sharp axe of the law. No doubt it may be replied that such an argument is simply the old excuse of extenuating circumstances. Hardly that. It is not intended as a plea *in extenuation. It is a charge of particeps criminis* against the law which invites the fault and the lawyers who are responsible for the retention of a system which many of them acknowledge to be bad.

Again, it may be said that it ought not to be possible for one lawyer to be able to retain a set of expert witnesses to testify on one side of a case, and for a second lawyer to get a second set of experts to testify on the opposite side. Such a criticism is perfectly just, and is particularly deserved in many of the damage suits which are so common in our courts to-day. There are lawyers known to the bar as ambulance chasers, who have runners constantly on the watch for accident cases, of which they learn through the daily papers. These unscrupulous members of the bar, with the aid of equally unscrupulous members of the medical profession, rob corporations of thousands of dollars every year. I can not say that I see any difference in the culpability, or that the doctor is more blameworthy than his principal, the lawyer, who brings the suit too often built up of manufactured evidence. They are a pair of precious rascals. I seek to excuse neither. It is the system, however, which renders their partnership possible. If the law rendered this evil alliance more difficult, or perhaps impossible, justice would be the gainer as well as the corporations. No amount of scolding from the bench will be effectual. Bad men have never been made to mend the evil of their ways by mere denunciation. They do not fear the fulminations from the bench, provided a sentence to jail does not follow. The householder who kept his silver on his doorstep might denounce the thieves who robbed him of his treasure with the full vigor of an unbridled vocabulary. No one would doubt the sincerity of his wrath, and the police would doubtless catch the rascals if they did not run too fast. The neighbors, however, would come to the conclusion that the wisest plan to prevent the loss of their valuables would be to keep them in a safe. So it is better to amend a system which is known to permit evil, and thereby prevent it, than to continue the system and imagine that anything can be accomplished by denouncing *the criminals who are the direct offspring of* the system itself.

There is, however, another class of cases in which the issues to be submitted to the medical expert are difficult or doubtful. Such are many will cases in which the testamentary capacity of the decedent is in question, damage suits in which the injury is of an obscure nature and the ultimate result doubtful, borderland cases of insanity, and criminal cases in which perplexing questions of medicolegal jurisprudence are likely to arise. There are no problems in medicine more difficult of determination than those which relate to testamentary capacity. How far may reason wander from the normal and yet the individual be of sound and disposing mind? Eccentricity of itself is not a sufficient reason for pronouncing a man insane, and yet there are many cases in which it is hard to say exactly what is the limit of eccentricity beyond which lies undoubted insanity, and the inability to make a legal will. There are criminal cases also in which the question of the criminal responsibility of the prisoner, by reason of a disordered intellect, is a matter of doubt. The medical profession can point to cases in this country and England in which insane persons have been punished for crimes committed, which would have been impossible had the individual been in a normal condition. In damage suits there are many cases in which, as a result of a violent shock from accident, the nervous system of the victim becomes deranged so as to make him a confirmed invalid. Confirmed, did I say? It is this very question which is most difficult to answer. Such cases as these are all debatable and likely to be subject to differences of opinion. Here we require not only the highest skill and the longest experience in the expert (yet from the decisions quoted it will be seen that there is no exact definition in the law as to what constitutes an expert), but it is also doubly essential on account of the doubtful or difficult nature of the questions involved that the experts shall approach the case with as little bias as the jury. No amount of invective from the bench will ever change human nature. Let us suppose the case in point to be criminal. The prisoner has been indicted for murder and the district attorney summons medical witnesses to support his contentions. On the other hand, the counsel for the prisoner summons experts before whom the case of the prisoner is laid for the purpose of defense. It is not in human nature that two sets of men engaged to examine the case of the prisoner, from two opposite standpoints, shall not be influenced by their point of view. There is nothing which is supposed to be more exact than the solution of mathematical problems. Nevertheless, astronomers invariably make a certain allowance for errors of observation in their calculations which is denominated the "personal equation." If the personal equation can enter into the abstruse problems of pure mathematics to an extent sufficient to require definite allowance, what value shall we give to the personal equation of two sets of medical experts called to decide a difficult problem in psychology or toxicology, and who view the question from different standpoints? What allowance shall be made for the personal equation when a blunder means not an error in the position of a star, but a life wrongfully taken by the state? It may be urged that bias should have no place in the minds of educated men, and that it ought to be possible for medical experts to consider the problems of medicolegal jurisprudence dispassionately without reference to the side which calls them. The law courts of a country are supposed to be as free from bias as is possible for any human tribunal, nevertheless the electoral commission which sat in the Tilden-Hayes case divided on strictly party lines. Purrington, in an article read before the New York State Association some years ago, quoted the *London Law Times* as follows: "It is curious that politics took sides, perhaps involuntarily, in deciding the case of Flood vs. Allen." In this celebrated case eight judges reversed the opinion of thirteen because the eight had the final decision, or what lawyers sometimes jocularly term "the last guess." Purrington further states that the same periodical cited a speech of Lord Brougham to show that in his recent day the decision of English judges might be predicated from their political leanings. Evidently in the law courts the point of view means much, not that there is the slightest suggestion that conscious bias is ever present. Facts like these, which might be multiplied almost indefinitely, show how difficult it is to get rid of personal equation, whether in the realm of pure mathematics, law or medicine. If the vapors of unconscious bias can drift behind the closed doors of our highest tribunals and cast the dews of prejudice within on the pure lustre of the shield of justice, what can we expect of a system which not only does not provide against the existence of prejudice, but, on the contrary, actually invites it?

The present law first paves the way for the appearance of witnesses as experts who may, nevertheless, be incompetent, then through the manner of their selection by the interested parties renders it almost impossible for them to be without bias, and finally proceeds to elicit their testimony by means calculated to gag the witness at exactly the point where his testimony becomes inconvenient to counsel or dangerous to the client. The hypothetical question, which is the method most frequently used in our courts for the purpose of eliciting the opinion of experts, is calculated rather to confuse the jury than to enlighten them, and frequently involves the serious logical fallacy of the *suppressio veri*. It is evident, if we are to continue to summon our jurors from all ranks of society without reference to previous education or present intelligence, this in itself constitutes a cogent reason why the evidence presented shall be clear and readily understood by even a limited intelligence and the most rudimentary education. There is a case (Haish vs. Payson, 107 Ill., p. 365) in which the hypothetical question covers two and one-half pages of the law reports. Hypothetical questions of less but still formidable length are common. In the Guiteau case, that of the defense comprises over 300 words, and Rogers states that the hypothetical question of the prosecution "is too long to quote." Only last week a hypothetical question was put to one of our ex-Presidents, which took an hour to read. It is true that the question is not addressed to the jury but to a witness; nevertheless, on this answer the jury must pass, and if the question is unintelligible or difficult to follow on the part of the jurymen, how are we to expect that their opinion of an opinion will be of value? The present legal status of the hypothetical question seems to be involved in as many contradictions as the legal view of the qualifications of the expert. Rogers, in his work on expert testimony, says that the hypothetical question is not improper simply because it includes only a part of the facts, and if framed on the assumption of certain facts, counsel may assume the facts in accordance with his theory of them, it not being essential that he should state the facts as they actually are. In Cowley vs. People, 83 N. Y., Judge Folger lays down this dictum and the following comment: "If the facts are in dispute, then there would be no room for the hypothetical question, if the question must state the facts as they exist, since the jury are to determine what are the facts." On the other hand, in Fraser vs. Jennison, 42 Mich., 206, the court said that a question "which assumes a state of facts not warranted by the testimony will not be allowed," and in our own state, in Dillebar vs. Home Life Insurance Company, 87 N. Y., p. 79, the court said that the testimony should tend to establish the facts embraced in the question. Judge Moore of the Supreme Court of Michigan said: "If one fact supposed to be true included in the question is untrue, then the opinion of the physician would be valueless." It is difficult for the layman to reconcile opinions which seem so contradictory. Judge Folger's opinion seems to mean that a lawyer may propound to the medical expert a hypothetical question which shall state certain unproved facts essential to his theory of the case, but which shall suppress unfavorable facts, and then insist on a categorical answer which may involve an actual suppression of the truth instead of the whole truth which the witness is sworn to reveal.

Judge Woodward's remedy for this state of affairs is an appeal by the witness to the court; nevertheless, it is the experience of the writer that the court has invariably directed the categorical answer, leaving to the re-direct or cross-examination to bring out the whole truth. The trouble with this method is that unless counsel be instructed by witness or an assisting expert as to the fallacy involved, he will let it pass. But it is impossible for a witness to suggest questions to counsel, nd the partisanship of a medical expert who is present at the trial for the purpose of assisting counsel is so evident to the jury as to deprive his testimony of any value and casts a shadow on all the expert testimony. A familiar and humorous example of the fallacy a categorical answer may involve is the old query, "Have you left off beating your wife?" Not a few of the hypothetical questions which are directed at the medical expert are designed to involve him in a dilemma which may not be so humorous or obvious, but which is, nevertheless, just as truly a dilemma, on either horn of which he will be impaled. Under Judge Folger's ruling, it would be perfectly possible for two different sets of experts testifying on opposite sides of the same case, to testify nevertheless on totally different statements of facts and be reprimanded by the court for disagreeing and lectured for their sins accordingly. In Davis vs. State, 35 Ind., 496, the same principle is laid down as follows: "After counsel have propounded to an expert a hypothetical question based on the facts assumed to have been proved in accordance with their theory of the case, opposing counsel may propound the same question based on facts assumed on the opposing theory." This leaves the jury to disentangle the truth from the masses of conflicting testimony, a task of which in many cases it is quite incapable. In the face of such a preposterous proposition as this, the medical expert is made the football of the bench, the bar and the press, and we are told that expert evidence is of little if any value. Says Judge Endlich of Pennsylvania (Am. Law Rev. 32, 851): "The vast majority of hypothetical questions does not and never will adequately and impartially present the actual or most probable state of the case," a statement which, in the light of the opinions quoted, seems to be axiomatic and therefore incontrovertible.

The medical profession is weary of being told that the fault is with it; weary of the ready and easy denunciations of the bench and the ill-considered jibes of bar and press. Men of the law, we protest against your system! We protest against its inconsistencies! We protest against it as inviting the chaos you are so fond of condemning! You admit, through the utterances of eminent judges and in the pages of your text-books, that you have no sufficient standard of qualifications. You admit that your system invites instead of preventing bias. You admit that the hypothetical question is not calculated to present all the facts to the expert. Nevertheless, up to the present time, in spite of the protests of the victims of an essentially vicious method; in spite of the reports of committees of your own profession and of joint committees composed of members of both professions concerned; in spite of the opinions of your most noted jurists, you absolutely refuse to change, but content yourselves with denouncing a profession which you wrong. You tell us that we must mend our ways. Judge Woodward, in the article before referred to, states his remedy as follows: "Where a doctor commits perjury, his fellow-doctors are apt to know it. Prompt expulsion from his medical society would tend decidedly to discontinue the imitation of his example." So this is the wonderful remedy which is to reform the evil! The medical society is invited to expel a man for giving opinion-evidence on the ground that his fellow-physicians will be apt to know that he has committed perjury. But how is the medical society going to prove that the opinion of which they complain and with which they do not agree, is not the opinion of the witness, and that he uttered said opinion with the intent to commit perjury? The difficulty with the judge's remedy is in its application. If the medical society attempted to expel a member on any save legal evidence, the judge would, if applied to for an injunction, be compelled to grant one against the use of his own prescription. If the medical society can secure legal evidence, so can the court; yet in another paragraph of the same article, the judge states that it is impossible to convict of perjury because the evidence is opinion-evidence. Rogers ("Expert Testimony") makes the same statement, and yet the judge asks a body of medical men to do what he confesses the courts can not do, although the same evidence of intent would be necessary in both instances. He asks of us impossibilities.

It is said that enlightened public opinion is the greatest destroyer of frauds. Enlightened public opinion, it is true, but it often takes a long time to enlighten. Bear witness, Eddyism, Dowieism, mental healers, osteopaths and kindred frauds in which the public delight! Has public opinion, although adverse to gambling with cards, ever been unfavorable to stock gambling, which is more vicious because more far-reaching in its evil results? Does it denounce the operations of so-called high finance, the stock watering and legerdemain by which stockholders and the public are robbed under the form of law, or, rather, in spite of laws ingeniously evaded by the aid of counsel skilled in the art of legal intrigue? Such remedies as these are nothing but the flimsiest of excuses and an evasion of responsibility on the part of those who are responsible for the perpetuation of the evil. To charge the medical profession with the faults of a system which it deplores, but is powerless to change, is nothing else than an attempt to shift the real responsibility—an effort to make of a self-sacrificing and honorable profession a hedge of defense and a hiding-place. It is always safe to abuse a doctor when he fails to please or does not succeed in accomplishing the impossible.

As a result of constant effort and complaint on the part of the medical profession, some desultory attempts have been made in this state and in Pennsylvania, Massachusetts and Illinois to bring about reform, but so far all efforts to change the system have either been strangled in the legislature or come to an earlier death at the hands of the bar associations of the different states. In New York, this society appointed a committee to co-operate with a similar committee from the bar association, but after dragging on for two or three years, the committee reported its inability to accomplish anything. In Pennsylvania, the committee's report, prepared by Judge Endlich, was disapproved when it came up in the bar association of that state, although if its recommendations had been carried out it would have put an end to the evil practices for which we are held responsible. It is not the intention of the writer to minimize the difficulties of the problem. Important questions of privilege, questions involving the constitutionality of suggested changes, the essential difficulties of making any change in a long-existing custom, but more especially the difficulty of getting lawyers to relinquish their present right of getting expert evidence where they can, when they can and how they can, all these difficulties we concede. They can not be solved, however, by an attempt to hold the wrong parties. Constitutional amendments have been passed in this state on much less important matters, and if it has been possible to materially change the law of evidence in so conservative a land as England, it ought to be possible to introduce reforms in the legal procedure of this state, which by many jurists of the highest standing are conceded to be necessary. Doctors are not learned in the law, and it is not easy for them to suggest remedies for a system which has inflicted on them so much unjust and unmerited criticism. Indeed, it seems to them that the legal profession ought to be willing to mend its own fences. Up to the present time, however, all that has been done by our brethren of the law is to invite us to expel erring experts from our county societies on illegal evidence, or to extend the provisions of the code of ethics "so as to embrace the conduct of the medical man when he assumes the rôle of expert witness." We respectfully decline to burn our fingers in either of the two ways suggested. To us, as mere laymen, it seems necessary to correct the faults of an antiquated system in order to bring about the much-desired reform.

It seems obvious, if we are to make use of expert testimony, that it should emanate from real and not from pseudo-experts. It ought not to be possible for a lawyer to introduce a recent graduate as an expert in insanity, when the law provides that he can not act as examiner in lunacy until he has been in practice for three years. An interval of five years in active practice after graduation is not too long for the blossom of theory to ripen into the fruit of experience. No student of medicine on graduation is competent to give opinion-evidence in court except in the simplest matters. Let the state require this interval before a doctor is allowed to give opinion-evidence. Such a law would not preclude his testifying on questions of fact. In addition, the state should require at the end of this period an additional examination, under the auspices of the present state boards as conducted by the three schools of medicine, to insure the fitness of the intending expert.

This is a very different proposition from the establishment of a state board of experts, to which objection has so often been made, for it does not confine the litigant to a small number of men selected by the state whose evidence is to have a higher value than that of the non-official witness. In fact, such a witness is not an official witness at all, any more than the physician who has passed his state board examination for a license to practice is an official doctor. Each has been stamped with the hall mark of fitness—nothing more. Examinations for promotion are held in the medical departments of the Army and of the Navy, and there is no good reason why the physician who wishes to testify as an expert should not show his special fitness for a work of such importance to the state and to both professions. For the purpose of providing for the period of transition, exemption from such examinations might be made in the case of men who had been twenty years in practice prior to the passage of the act, and to men in medical schools who hold positions above the rank of instructor; also of the hospital man who has spent at least five years in the service of a hospital of at least fifty beds. Such exceptions as these may be necessary as a temporary expedient only, and in order to provide for the inconveniences involved in any sudden change. The problem of securing an expert witness without bias is more difficult, since under the law every client is protected in his right to offer any evidence which may be material. Consequently, at present he can not be prevented from selecting his own witnesses, whether lay or expert. Nevertheless, just as long as this practice continues in the case of the medical expert, we shall rarely be able, even in the most conscientious witness, to provide against the unconscious bias which may exist on the bench of the highest courts as well as in the minds of the faculty. This it is which is the chief evil in the system. No doubt some improvement may be expected from the erection of a proper and moderate standard of qualification such as has been suggested, but to do this and yet leave untouched the greatest of the evils complained of, would be very ineffectual therapeutics. The most feasible and simplest way of bringing about a change in this respect, although not ideal, is to leave the selection of the experts for both sides in the hands of the judge. In the long run, we should get better results than if the selection of the experts were to be left in the hands of a state body like the New York State Board of Regents. Moreover, I believe it would be much easier to get the consent of the bar to such a change. An objection by Judge Bartlett of the appellate division of the Supreme Court to entrusting the bench with such a function is that a man may be a good judge of law and yet be a very poor judge of doctors, a statement with which those of us will agree who have never had the privilege of treating judicial gout or dyspepsia. As long as there is no standard of qualification, this objection will have much force, but if a judge were compelled to make his choice from men who possessed the qualifications suggested, he could not make any very serious blunder; and while it is true that the very best men would not always be selected by the bench, not as good perhaps as by a state board, yet we should be in a fair way to get unbiased opinions at least and a reasonable degree of competence. Undoubtedly it would also be better for the state to pay the experts a fixed fee, such as was suggested in this state some years ago, the minimum being $10, which is too small, and the maximum $100, this latter fee being for the entire day in court. Such a practice would, however, have the serious objection of increasing the burden of the taxpayers. The alternative to this would be to fix the fee at $100 a day, with a minimum of $25 for any opinion-evidence, however short, and leave the payment of the experts to the suitors, as at present. Even under this plan it would no doubt be possible for a designing lawyer to suggest that while the legal fee was $100, further compensation would be forthcoming if the opinion was favorable to his contentions. I know of no way of providing against such a possibility. We can only approximate, never secure, perfection in this world. Men will continue to be avaricious, untruthful, ready to do evil rather than good, so long as the sun rises and sets in this sad world. There is no specific for sin except in the new heavens and the new earth, and the man who demands perfection in any system, whether it be of law, theology or medicine before he accepts it, will have to go to his grave unshriven, intestate, with a coroner's certificate as his passport to the tomb.

Finally, in the matter of the hypothetical question, I believe that the medical profession would be glad to see it abolished entirely in accordance with the recommendations of Judge Endlich of Pennsylvania. If it is to be retained it ought to be submitted on an agreed statement of facts. In no other way can it be made use of without confusing the jury and of necessity antagonizing the experts. How can they be expected to agree if they testify on different statements of fact? Much time might be spent in discussing the substitutes for the hypothetical question, but the writer is conscious that there are limits to the forbearance of the most lenient audience. It has been his intention rather to throw into the strongest possible relief the faults of the present system which need correction, than to enter into a critical examination of the many different remedies which have been proposed. After all, in law as in therapeutics, it is better to attack the cause of an evil than to treat symptoms, and the investigators who have discovered the causes of a disease have gone a long way toward preventing it.

This matter concerns two learned professions. On one hand stands the profession of law, the protector of the feeble against the mighty, the safeguard of all government, dispenser of equal justice. On the other stands the medical profession with high ideals of self-sacrifice, high professional standards of right and wrong—the wish to give of their best to individual and public alike. Shall these two great professions stand arrayed against each other on so vital a matter? Must there be no further progress toward reform? Shall we continue to waste our breath and printers' ink in mutual recrimination? The problem is difficult but not impossible of solution, and it must be solved. The profession which boasts a Taney, a Marshall, an Evarts and a Taft, will not always refuse justice to the profession which has given to the world a Jenner, a Koch, a Behring and a Reed.

CHRONIC ADHESIVE SCLEROSING PERITONITIS, OR PLASTIC PERITONEAL SCLEROSIS.

HORACE G. WETHERILL, M.D.
Professor of Gynecology and Abdominal Surgery, Denver and Gross College of Medicine; Surgeon-in-Charge, Denver Maternity and Woman's Hospital; Surgeon St. Luke's Hospital; Gynecologist, National Jewish Hospital for Consumptives.
DENVER.

The "chronic adhesive sclerosing peritonitis" of the Germans is a rare disease, and, so far as I can determine, has escaped recognition and description in most of our American text-books. One or two articles in the current medical journals of the last ten years describe conditions resembling true chronic adhesive sclerosing peritonitis, but the disease is nowhere accurately described as a distinct pathologic entity. This is all the more remarkable, as it appears to be well known in Germany, Virchow having alluded to it as long ago as 1853, and Riedel has recently considered the subject comprehensively. In the new edition of the "Handbuch der Practischen Chirurgie" by von Bergmann, von Bruns and von Mikulicz (Vol. 3, p. 85), a detailed description of the disease is to be found and the pathologic picture is so closely similar to the findings at the operation and necropsy in the case here reported that ours was readily recognized as one of chronic adhesive sclerosing peritonitis, though none of those who saw the case had ever seen any other and none of the surgeons of large experience who were told of it had any recollection of having encountered one like it.

According to the description in the handbook mentioned, it may occur at one or many points in the peritoneal cavity, but the areas about the female genital organs, the gall bladder, the flexures of the colon, the posterior part of the peritoneum, the root of the mesentery, the mesentery of the sigmoid flexure and the omentum are the points of selection. As a consequence of the chronic inflammation, thickening of the peritoneum results, which leads to shrinking.

It is alluded to as *Narbenbildung-Schrumpfung, Adhasionbildung* and adhesive sclerosing peritonitis, the latter name being descriptive of the pathologic picture presented by the disease. It is further stated that chronic adhesive and sclerosing peritonitis may be a sequel of acute infections of the intestines. All parts of the abdomen where circumscribed acute peritonitis often takes place are liable to adhesive processes. Trauma of the abdomen often gives rise to it, as well as operative procedures. The complaint may, however, start in a chronic form and reach a high state of development without an acute stage having preceded and without the patient being able to give a definite cause for its onset. The functions of the large intestine are very much interfered with, through adhesions in the cecum and flexures and mesentery of the sigmoid. Chronic constipation is, therefore, a frequent result of such conditions.

The English terminology of the forms of chronic peritonitis is so involved and the descriptions of the various phases of the disease so vague that the impression is forced on one that proper classification of such diseases as may produce this effect has not yet been made.

Under the term "Proliferative Peritonitis" (on p. 603) in Osler's text-book, a brief description of the condition here considered may be found while the exceptionally exhaustive and able papers of A. G. Nicholls[1] treat of "Chronic Hyperplastic Peritonitis," and Douglas' "Surgical Diseases of the Abdomen" describes a form of fibroid tubercular peritonitis which resembles true chronic adhesive sclerosing peritonitis; and A. J. O. Kelly, in a paper on "Multiple Serositis," makes allusion to like conditions.

The essential characteristic of chronic adhesive sclerosing peritonitis, as described in the handbook I first mentioned and as observed in our case, is extensive subperitoneal fibroid infiltration or scleroses, without ascites and without "serofibrous or fibrino-purulent exudation."

This would seem to demand for the disease a different classification from those pathologic processes which produce the well-known icing liver of Curschmann, and though it may be of tubercular origin, that hypothesis is far from being proved, and it is manifestly improper to confuse it with specific tubercular fibrosis, as described by Douglas.

---

[1] Studies from the Royal Victoria Hospital, Montreal, 1902, and The Journal A. M. A., March 14, 1903.

Indeed, chronic adhesive sclerosing peritonitis would appear to be primarily not a peritonitis at all, but a distinct affection of the subperitoneal and visceral fibrous or connective tissue, the feature of adhesive peritonitis supervening as a result of traumatism, operation or of transmigration of intestinal bacteria through impairment of the natural resistance of the tissues.

In view of this fact might it not be better for us to agree on a name for the disease which would more closely indicate its characteristics, as is done by the Germans, or perhaps even simplify the title they have given it by calling it plastic peritoneal sclerosis?

This name, through the broad significance of the word sclerosis, suggests chronicity, slight inflammatory action, contraction, and the histologic elements actually involved, while the word plastic indicates the secondary effect of the malady.

THE NARRATION OF THE CASE.

The case here reported was seen with me previous to the first operation by Dr. Leonard Freeman of Denver. He assisted me at the first two operations, and was principal at the third, in which I acted as his assistant. To Dr. Freeman is due the credit of suggesting the possible character of the malady, he having read the article above quoted just prior to the last operation, his surmise being amply verified by this operation and the subsequent necropsy. Drs. J. N. Hall and J. E. Kinney were also valued consultants throughout the later stages of the disease, and Dr. J. A. Wilder examined the tissues and reported the pathologic findings. To all of them I desire to make acknowledgment and offer thanks.

Previous History.—The patient came to Colorado about twelve years ago because of chronic and intractable malaria. She had been married twenty years and borne two children. the last ten years ago. She was 45 years of age, and had never been robust.

Present Trouble.—About seven years before her death she had a free hemoptysis, and for many years she was subject to attacks of vomiting, pain and flatulency, accompanied and followed by frothy, yeasty and very offensive stools. Her nutrition and digestion were never very good, and during the last two years of her life were poor.

In June, 1902, sixteen months before her death her malnutrition and distress became so profound as to demand interference, and as she presented at this time the classic symptoms of a chronic appendicitis and had a very movable right kidney, it was determined to operate for these and to make an exploration of all the abdominal organs.

First Operation.—An operation was performed June 17, 1902, at St. Luke's Hospital, with the assistance of Dr. Freeman. The vermiform appendix was removed, the right kidney fixed to the parietes and an exploration of the pelvic and abdominal organs made. In making the closure of the abdominal wound, however, a difficulty was encountered, the significance of which was not appreciated at the time, but in the light of subsequent events it assumed a place of great importance, and had we known chronic adhesive sclerosing peritonitis then as now, it would have lead to an immediate, positive diagnosis. This phenomenon was a total inability to approximate the peritoneal surfaces below the muscles, the peritoneum having contracted from the edges of the cut muscles so that it could not be brought together. It did not then give us the impression of being thickened, though could we have observed it with our present knowledge of the disease, we probably would have found it so. No other pathologic conditions were found at this time, sixteen months before death.

This phenomenon must be regarded as pathognomonic of this disease and every effort must be made to cover the wound, as otherwise conditions favorable for the development of the most serious phases of the disease are left, the viscera adhering to the abraded surfaces and giving rise to serious complications, as the sequel in our case demonstrated. If the peritoneal surfaces can not be approximated, a covering of omentum should be made, if, indeed, the disease has left any omentum available.

Result.—The immediate result of this operation was to improve the general health and comfort of the patient. The old diarrhea was arrested and gave place ultimately to constipation. After about a year had elapsed, however, anorexia, nausea, vomiting, constipation, flatulency and finally great rectal pain and tenesmus with reflected pains into the back and legs developed. Examination revealed a mass underlying the upper end of the scar of the old incision, which seemed to involve the pyloric end of the stomach and to be attached to the pancreas. A tight and rigidly undilatable stricture of the rectum was found, one-third of an inch in diameter, three inches from the anus, and the pouch of Douglas was filled with a tumor, three inches in diameter, which seemed to be incorporated with the rectal obstruction. Though the patient was not cachectic, the presumption that the case was cancer seemed so great that this diagnosis was uppermost in our minds, though the hope was held out to the patient and family that it might not prove to be so.

Second Operation.—An immediate operation for the relief of the rectal obstruction was urged, and on Sept. 30, 1903, was done at the Woman's Hospital in Denver. The usual incision for an inguinal colostomy was made, and through this the pelvic and pyloric masses were examined. The pelvic tumor proved to be a solid tumor of the right ovary, three inches in diameter, and was easily tied off and removed, as it was pedunculated, though firmly impacted and wedged in the pelvis. The rectal band was entirely distinct from it. The rectum sigmoid and whole colon were densely packed with hard feces, and the pylorus and intestine were matted together in a huge mass which was very adherent to the old scar. The detachment of these adhesions was impossible. The sigmoid was drawn through a valve-like opening and the usual colotomy made on the fourth day. The feces were washed out from day to day and so the rectal tenesmus was relieved and the comfort of the patient promoted. Again the difficulty of the first operation was encountered in closing the wound. The contraction was much more pronounced than before, and again its true meaning was not understood.

Result.—No infection followed, and in three weeks the patient was up in a chair and doing well, when, after some unusual article of diet, great pain and tenderness, with gaseous distention, developed. No relief could be procured through the fistula, and it became evident that a complete intestinal obstruction had formed above the fistula, and as the whole colon could be distended with water and then emptied it was evident that the small bowel was involved.

Hopeless as the case now appeared, the determination was reached to again operate for the relief of the obstruction.

Third Operation.—Dr. Freeman undertook this last operation, I assisting. The probable nature of the case was now suspected, as the German account of the disease had come to his attention.

A long incision was necessary, and the whole length of the distended small bowel was examined to determine at last that the point of absolute obstruction was near the lower end of the ileum and that it was solidly attached to the underside of the inguinal colostomy incision at the point where the peritoneum could not be made to cover it. This attachment was so firm that the bowel was torn completely across in an effort to separate it, and it was necessary to resect about six inches of intestine and make an anastomosis with a Murphy button. In order to get around the mass of adhesions about the pylorus which involved the stomach, gall bladder, duodenum and pancreas a gastro-enterostomy was done, though with great difficulty, as the stomach was contracted to about the diameter of the large intestine and was enormously thickened so that the shank of the Murphy button was scarcely long enough to reach through and lock, and the purse-string suture in the stomach wall could not be made to pucker the tissue about it. Much difficulty was again encountered in closing the wound in the peritoneum.

Necropsy.—Fourteen hours after this operation the patient died, and consent for a partial necropsy being procured, the following striking pathologic conditions were found: There was a general shrinking, thickening and contraction of the peritoneum everywhere, but it was most marked in the regions indicated as the favorite sites of the disease, i. e., about the pylorus and gall bladder, the flexures of the colon, the rectum and pelvic organs, the mesentery and the peritoneum covering the posterior wall. There was no ascites and no serofibrous or fibrino-purulent exudation on the peritoneum.

The stomach wall was in places more than half an inch thick and the gall bladder, duodenum, pylorus and pancreas were so matted together as to be quite inextricable. The pancreas was small and so infiltrated with connective tissue growth as to be almost cartilaginous in consistency. At three points the small bowel was so tied down by contraction of its mesentery as to have its lumen greatly interfered with, and the caliber of the rectum at the point of constriction was reduced to a diameter of less than a quarter of an inch, with its walls quite three-fourths of an inch in thickness. A loop of the extreme lower end of the ileum was very firmly attached to the bladder. There was also a firm stricture at the pyloric end of the stomach of only about one-third inch in diameter. The mesentery of the small bowel was rather thickly studded with small miliary nodules, which were apparently not tubercular.

Most curious of all was the condition of the kidneys: The right, which had been fixed at the first operation, being so firmly attached as to make its removal almost impossible, and both the right and left kidneys presenting a condition of cystic degeneration or hydronephrosis due to pressure on the ureters by the shrinking fibrous posterior peritoneum. The liver and spleen were normal, though the superior surface of the liver was adherent to the diaphragm. At the site of each of the former incisions through the peritoneum the viscera were firmly adherent to the cicatrix. The cut surfaces of the thickened stomach and rectal wall were white and glistening and showed an enormous hyperplasia or connective tissue growth. This was also true of the pancreas and the mesentery of the bowel, which was very much thickened and shortened throughout. None but the abdominal organs were examined.

Incidentally, it may be mentioned that for about fifteen years this woman had a peculiarly dry, wrinkled and shrunken skin, with almost a complete arrest of secretion from its glands, coincident with the development of the first abdominal symptoms, which may have been a part of the general pathologic process.

Microscopic Examination.—Dr. Wilder's report is as follows:

The ovarian growth measures 3¼x2½x1½ inches. The surfaces are smooth, lobulated and surrounded by a connective tissue capsule that is firmly adherent to the underlying tissue. The tissue cuts with considerable resistance, has a pinkish, flesh-colored appearance and is firm throughout, no areas of necrosis or caseation being found.

Sections made from different parts, including both periphery and center, had the same general appearance. They consist entirely of connective tissue fibers and cells, in some places the former predominating, in other places the latter. The most notable feature of the cellular material is that it is in all stages of fatty metamorphosis. Blood vessels are present in moderate number, and apparently have normal walls. I am unable to find anything suggestive of ovarian tissue in the specimen examined.

Sections from the stricture of rectum show nothing but a dense mass of adult fibrous tissue. Very little cellular material is seen. The vascular supply is poor, but where present the vessels have well-formed walls. No evidence of degeneration can be found.

Sections from the cardiac end of the stomach show an advanced stage of interstitial gastritis, and an enormous increase of connective tissue is seen, which has deeply penetrated the muscular coat. A marked increase of interstitial tissue is seen between the tubules, which have themselves undergone extensive atrophic changes. Sections taken near the pylorus have a similar appearance. Sections from the pancreas show a marked interstitial pancreatitis, the trabeculæ being greatly thickened and the cells apparently suffering from pressure atrophy. The omentum also shows a marked increase in fibrous tissue, and the lymph nodes enclosed in it show hyperplasia of lymphoid cells, with an increased amount of connective tissue in the trabeculæ.

POINTS OF INTEREST.

The points of greatest interest in connection with this case are:

1. The rareness of the disease.
2. The failure to generally recognize and to fully describe it on this continent, though it has been long and well known abroad.
3. The pathognomonic sign—inability to unite a shrinking peritoneum once divided during the course of an operation, which, so far as I am aware, I am the first to observe and describe.
4. The essential chronicity of the disease, as indicated by the long-standing symptoms, otherwise unexplained, and by the shrinking and retraction of the peritoneum at the first operation, sixteen months prior to her death, which proved the previous existence of the malady, and that it was not directly or indirectly the result of the operation.
5. The great importance of covering all denuded surfaces when before or during an operation chronic adhesive sclerosing peritonitis is diagnosed.
6. The characteristic subperitoneal connective tissue hyperplasia which is the pathologic feature of the disease.
7. The shrinking or contraction of the peritoneum caused by it, the clinical feature.
8. The possible significance of a somewhat similar pathologic process taking place in the skin coincident with unusual gastrointestinal symptoms otherwise unaccounted for.
9. The possible diagnostic value of this syndrome.
10. The danger of serious sequelæ incident to its surgical treatment.

A STUDY OF GOUT.*

JAMES D. MORGAN, M.D.
Physician at the Garfield Hospital.
WASHINGTON, D. C.

That the pathology of gout has not kept pace with the lines of distinction that have clinically been drawn, is much to be regretted, but we do know that it is the fibrous element which is most affected in chronic rheumatism, the synovial membrane with degeneration later on in the cartilage and bone in arthritis deformans, and the kidneys and blood primarily in gouty affections causing deposits of urates in the joints. If one should say that it was the uric acid in excess in the blood, in the form of urates, that was the cause of gout, he would very rightly be met with the assertion that there were other diseases with excess of urates in the blood and which did not have the manifestations of gout. A similar wrong conclusion would be to attribute the cause of arthritis deformans to micro-organisms, for it is known that the investigators do not agree in the description of these organisms and that they have been found in other diseases, and so far inoculation has failed to reproduce the disease in animals. McCrae of Johns Hopkins, in a recent excellent paper on arthritis deformans, says that could we determine a definite organism to be associated with the disease, the matter is settled. In his series of 110 cases of arthritis deformans he has never succeeded in obtaining any results from cultures. In reference to the association with previous gonorrhea, he reaffirms the established fact that the disease is very uncommon among the colored race, among whom gonorrhea is almost a general occurrence. While the whole question must as yet be left open, he is of the opinion that the evidence seems to point to the infective theory.

---

* Read before the Medical and Surgical Society of Washington, D. C.

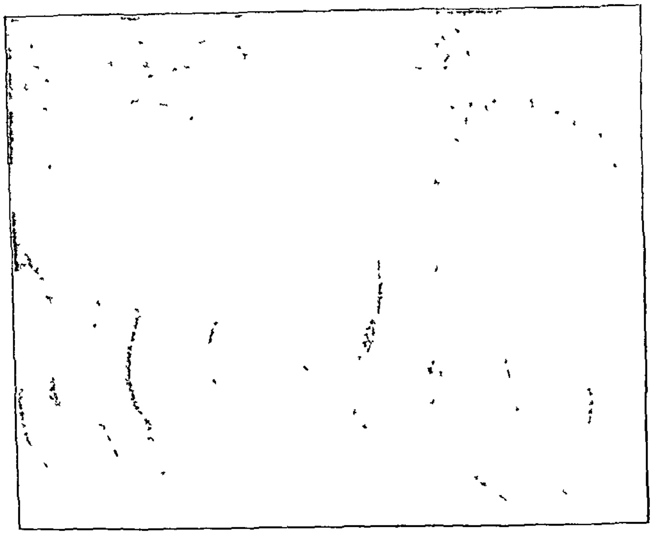

Fig. 1—Gouty hands.

The clinical pictures of rheumatism, gout and arthritis deformans are fortunately so often clearly presented that a pathologic consideration of the anatomy of the parts is not necessary. When our vis-a-vis at cards can chalk down the score with his knuckles, we do not need any further demonstrations to tell us the party is suffering from chronic gout. We have all seen, as Niemeyer writes, such cases where the diagnosis was strongly supported by the experience of the patient. The patients themselves have not only remarked that they could expose themselves to catching cold with impunity, while the return to careless diet and the use of beer and wine always made them worse, but they also observed that anti-rheumatic treatment did not improve their case.

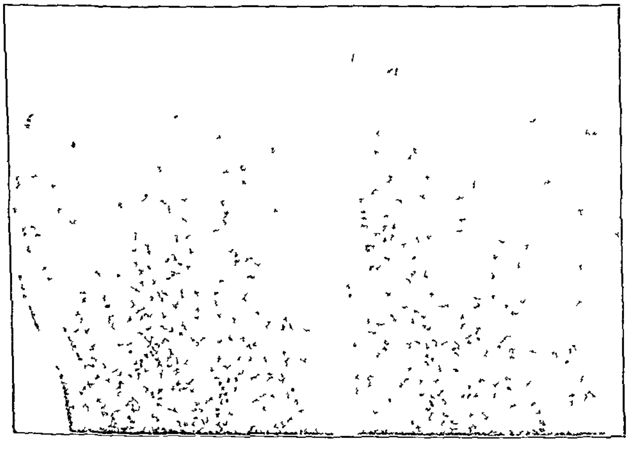

Fig 2—Radiograph of gouty feet.

A recent case which is very apropos in this connection had been diagnosed before entering Garfield Hospital as arthritis deformans, and so far as the name goes, it is a case of deformed joints; but when one considers the history and looks at the joints pathologically and fluoroscopically he is impressed with what marked distinctions can be drawn between this case and chronic rheumatism and arthritis deformans. The age, sex and mode of life of the patient are first to be considered. He has tried to get all out of life he could in a short time; has disregarded all sensible and rational ways of conserving his bodily vigor and has choked and engorged his system with the products of faulty metabolisms, and has burnt the candle early and late at both ends. His kidneys, as nearly all these cases show, are considerably hardened, and this process of connective tissue sclerosis extends to other organs besides the blood vessels and heart. Outside of the tophi being absent from the ears and eyelids, the case is peculiarly characteristic with its large deposits on tarsophalangeal and carpophalangeal joints, with also enormous incrustations around the olecranons. What clinched the opinion in this case outside of the fluoroscopic view, which showed permanency to light of the deposits in contradistinction to the darkened areas in arthritis deformans, were the finding of the crystals of urate of soda in the joints. A comparison of the radiographs of the normal joint and those of gout and of arthritis deformans (taken through the courtesy of Walter Merrill, M.D.), will show the difference in deformity and destruction that goes on in these diseases.

It might be said in gout that the deposits *per se* do not destroy the joint or articulation, but bring about deformity or disarticulation from the pressure of the increasing deposits in and around the joint. In chronic rheumatism of the severest type, "we are often astonished how little in appearance the joint may be altered" (Osler), whereas, in arthritis deformans, a most extensive destruction of cartilage and bone, with marked deformity, often follows.

In considering gout there are many diseases that simulate it as regards the affections of the joints. The sex, age, habits and inheritance, as I have said, will often separate the case from chronic rheumatism, arthritis deformans, gonorrheal or tubercular arthritis, Charcot's tabetic knee, or that of syringomyelia and other arthropathies of neuropathic origin. Garrod found that "in 500 cases of arthritis deformans, 411 were in women"; others give the percentage as high as 85, and in women who had passed the menopause, with no antecedent history of intemperance, indolence or luxury. Monro, in the same disease, has noted that "the hands suffer more than the feet," and symmetry is often characteristic; that the knee, shoulder, hip, hands and spinal column, etc., are apt to be attacked in the order named. In the 110 cases which have been tabulated from Dr. Osler's wards by Dr. McCrae, he does not find great disproportion between the sexes; also he remarks that the affection, he believes, is not so symmetrical as the writers are very fond of emphasizing. He lays stress on the contrast between the alcoholic history in gout and arthritis deformans, and the striking disparity between the involvement he found of the fingers and of the toes—the great toe being affected in only 6 cases of this large series of arthritis deformans.

We find that in 95 per cent. of cases of gout, the disease originated in the metatarsophalangeal joint; that fermented liquors with a full stomach have been the shibboleth of the sufferer, and that a good proportion of cases have to thank their sires for vitiated diathesis of gout. Dr. Darwin, an English physician of great note, affirms that he never saw a case of gout where the person did not drink freely of fermented liquors. such as beer and wine.

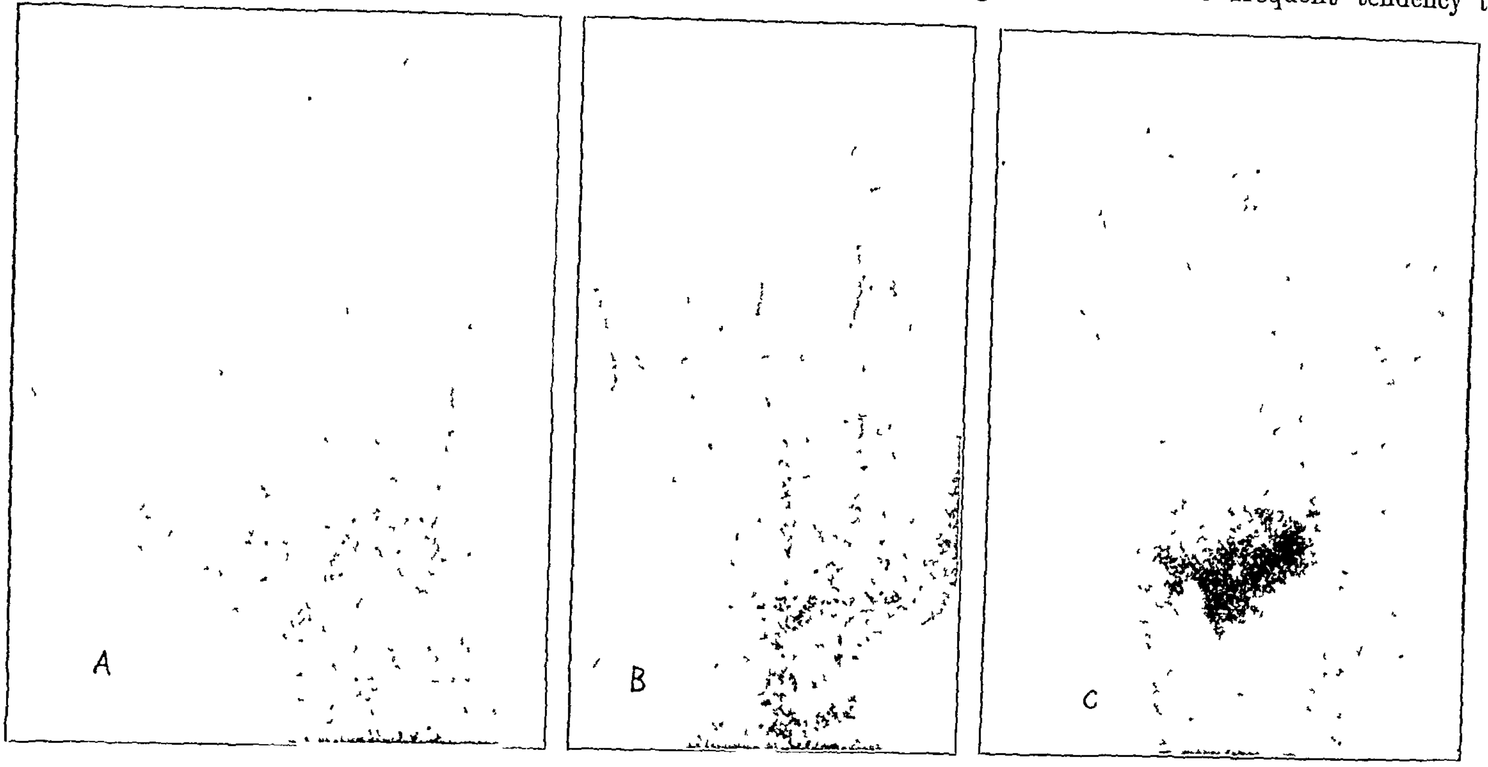

Fig 3—Radiograph of (A) gouty, (B) normal and (C) arthritis deformans hands

Heberden's nodes, which are described by most authors—some considering them rheumatic, others gouty—are small rounded growths arising principally from the phalanges of the fingers, and produce considerable deformity of the joints, without, as a rule, exciting much pain. They contain no mineral constituents, but are made up principally of fibrous tissue, and are found mostly, as Lyman says, in elderly women. Heberden believes that they have no connection with gout, being found in persons who never had it; whereas, the gouty, crab-eyed indurations are rough and uneven and are composed of urates. Levison of Copenhagen draws a marked difference between gout and arthritis deformans. Gout has a strong hereditary predisposition (77 per cent.); it occurs more in the males, and in those who have used beer or strong wine. Workers in lead have a decided tendency (33 per cent.), and dyspeptic and renal colic often precede the acute attacks of gout. The urine is often found deficient in urea, and uric acid and hyaline and granular casts are not unusual. Tophi are found on the ears, eyelids and joints. The Roentgen photographs of the foot or hand show the clear lines between the bones, and even the large deposits of urate of soda are quite invisible. In arthritis deformans the articulation affected by the disease, even if it be not developed far enough to cause stiffness or enlargement of the joint, has lost its clear, transparent appearance and is almost black in color.

To draw a line sharply between acute gout and rheumatism is often very difficult, especially if the gouty pains occur simultaneously in many joints and are associated with considerable pyrexia. A consideration of the habits and occupation of the individual, the sex and age, the estimation and comparison of the urea, uric and phosphoric acids output, as suggested by Futcher, and the test as recommended by Garrod for uric acid in the blood, may be of great value. The higher temperature curve, with the drenching acid sweats, is in marked contrast to the rather low or afebrile temperature, with a greater and more frequent tendency to fluctuation between great agony and absolute well-being. Aretæus has known the Olympian race to be won by those who were in the throes of gout the night before.

919 McPherson Square.

A STUDY OF A CASE OF GREEN URINE,

RESULTING FROM THE ADMINISTRATION OF METHYLENE BLUE IN A PROPRIETARY REMEDY.

JAMES M. COOPER, M.D.
ANN ARBOR, MICH.

While cases of green urine are by no means unknown, the circumstances surrounding a recent case are so much out of the ordinary that they will interest the general practitioner. On the other hand, the report will not be without scientific interest and value, since one of the foremost American text-books on diagnosis, in speaking of this condition, dismisses the subject with the statement that, "while green urines have been described, the cause of the color has not been definitely ascertained."

THE CASE REPORTED.

On Dec. 1, 1903, there was submitted to me for examination about 120 c.c. of urine of a bright grass-green color, and possessing a peculiar aromatic odor, not unlike that of oil of juniper or wintergreen. The patient was a woman, 76 years of age, who had been for a long time troubled with sciatic rheumatism, for which she had tried numerous remedies, but with little permanent beneficial effect. She first noticed the passage of colored urine on the morning of November 27, the day after she had begun taking some pink-colored pills known as "Magic Regulators," which had been sent to her as a sample by a patent medicine concern located at Jackson, Mich. With the pills were directions to take one before each meal, followed by a glass of hot water; and there was also enclosed a circular reading as follows:

"A simple test: To prove the action of our 'Magic Regulators' on the kidneys, the organs which in rheumatism are always diseased and fail to do their work, allowing the poisonous acids to accumulate and lay the foundation for a long and painful run of rheumatism, watch the color of the urine voided. If it assumes a light-blue or greenish color, you may rest assured that the 'Magic Regulators' are doing their work."

In all, 14 of the pills were taken, as directed, and during this time the patient continued to pass urine of practically the same color as the sample submitted for examination. During this time the patient's diet consisted largely of bread, butter, milk, tea, meat, and potatoes. The vessel into which the urine was voided was clean, as was also the bottle in which the urine was sent for examination.

THE LITERATURE OF GREEN URINE.

Instances in which green urines have been passed have been known from very early times. A comparatively large number of cases are to be found reported, particularly in French literature. Within the last few years several papers on this subject have appeared in Scottish and English journals, but American literature seems to be singularly lacking in this regard.

Braconnot[1] describes two cases of blue urine, from which the color could be removed by filtration. Hassall[2] states that the above blue color was due to the presence of particles of indigo deposited in decomposing urine. Hughes[3] reports a case in which blue urine was passed from the bladder. Garrod[4] records a case of a child passing green urine after sucking a cloth dyed with indigo. Fletcher[5] reports a case of blue urine being passed after methylene blue had been taken unintentionally. Good[6] reports a case in which the blue color was diagnosed as indigo, although the patient was shown to have taken methylene blue.

Dr F. Parkes Weber,[7] in an article entitled "The Occurrence of Green or Blue Urine and Its Most Frequent Cause," describes several cases in which green or blue urines were passed, and gives a detailed account of the various tests by which methylene blue can be recognized in the urine, noting especially the differences in the reaction of an ordinary solution of methylene blue and a solution of methylene blue in urine.

Stockman[8] reports two cases in which blue or green urine was passed, and which on examination was found to be due to methylene blue, which in one case had been given to the patient as a practical joke, in the form of pilules densely coated with pink-colored sugar. For purposes of comparison, the urine of a third person was examined after two grains of methylene blue had been administered intentionally. Stockman states that the reactions given by the urine varied even in the cases in which methylene blue was known to have been administered. In the first case, when the fresh green urine was shaken with chloroform or amyl alcohol a blue color was extracted, leaving the urine a deep yellow, and he explains the green color of the urine as being due to the mixture of these two colors. At times the urine passed by this patient was dark blue, and at other times bright green. Stockman concludes that when methylene blue is taken internally a blue and a green pigment, probably a yellow pigment, and probably also a colorless chromogen appear in the urine, and that these yield reactions and spectra which are slightly different. In Stockman's second case, the patient, who was suffering from a cystitis, passed one specimen of greenish urine. The coloring matter was insoluble in chloroform, amyl alcohol, ether and benzol, and was decolorized by liquor potassii. He is unable to state either the source or the nature of the pigment.

Dun and Douglas[9] report what they state to be probably the first recorded case in which methylene blue was made use of to delude the patient into a belief in the efficacy of the remedy administered. In this case the remedy was taken for chronic rheumatoid arthritis by a lady 65 years of age, being administered in the form of capsules, sent to her as samples by an American concern. The patient was instructed to observe the urine for evidence of the fact that the remedy was taking effect, it being stated that the urine would come to be of a decided bluish tint. A sample of the urine was examined by Dr. Douglas, who decided that the coloration was due to methylene blue, which had been added to the patient's medicine in small amounts. None of the capsules could be obtained for examination. The urine was of a fine, deep, transparent green, with a slight bluish tinge, and possessed the odor of anise. It decomposed more slowly than usual, remaining free from disagreeable odor, at room temperature, for over a week. The results of a number of tests are given, which make it practically certain that the pigment was methylene blue.

EXAMINATION OF THE URINE.

The sample examined in this case consisted of about 120 c.c. of a particularly brilliant grass-green color, with the peculiar aromatic odor above described. It was slightly acid and had a specific gravity of 1020. Portions exposed to the air for some days did not change color, and underwent decomposition very slowly. One ounce was poured into a sterile bottle, and has been kept at room temperature for three weeks and is still slightly acid, and without any marked odor of decomposition. Portions to which were added mixed cultures of colon and typhoid bacilli and various other germs obtained from water, were decolorized after being kept for several days at room temperature, but the green color could be restored on shaking the tube. The pigment was found to be insoluble in ether; and on treating the urine with both dilute and strong hydrochloric acid, no change in color was observed, even on boiling. A few drops of a 10 per cent. solution of sodium hydroxid decolorized the urine, the green color being restored on neutralization with hydrochloric acid. Ether failed to take up the pigment, however, at all stages of this reaction. The urine was unchanged in color on boiling, but filtering slightly decreased its intensity, owing to some of the pigment being taken up by the paper. Both chloroform and amyl alcohol, when shaken with the urine, removed the green color completely, leaving a bright golden yellow. On evaporating the chloroform and amyl alcohol solutions of the pigment to dryness over the water bath, a greenish substance was obtained, which, on treatment with strong sulphuric acid, became brown and brownish yellow, and on dilution, at first greenish and finally was decolorized.

About 25 c.c. of the urine was then evaporated to dryness over the water bath. As the pigment dried it changed in color from green to light brown, but on washing with alcohol the green color was restored, and the pigment passed into solution. The residue was washed several times with alcohol, and the washings carefully evaporated to dryness at about 60 degrees. A portion of the solid pigment obtained on evaporating the alcoholic extract was treated with strong sulphuric acid, which changed it to a brown color and decolorized it on dilution. A dilute water solution of methylene blue when evaporated to dryness and treated in the same way, gave a similar reaction. The remainder of the green pigment obtained from the alcoholic extract was taken up with water, in which it was readily soluble. This water solution was of a deep bluish green color, similar to the original urine, but slightly darker, it being more concentrated.

Portions of the original urine and of the aqueous solution of the pigment obtained as above were then treated with a few drops of Weingärtner's reagent (tannin, 25 g.; sodium acetate, 25 g., and water, 250 c.c.), which precipitates basic anilin dyes. A fine green precipitate was obtained in both instances, the filtrate from the urine being of a bright golden yellow, similar to highly colored urine, and that from the aqueous solution of the pigment being clear. This reagent, therefore, completely removes the pigment from its solution in water and urine, and indicates it to be a basic anilin dye. The precipitate in both instances dissolves readily in alcohol, giving to it a light bluish-green color. The reactions given by the aqueous solution of the dye obtained as above were similar to those given by the urine itself.

Moderately dilute solutions of the pigment extracted from the urine with amyl alcohol, and of methylene blue in amyl alcohol, when examined with the spectroscope, showed in both cases a single, well-defined band in the red at a considerable distance from the sodium line. The urine also, when examined with the spectroscope, showed this same absorption band, but less markedly.

EXAMINATION OF THE REMEDY TAKEN.

A sample box of the pills, similar to those taken by the patient, was obtained. They were bright pinkish red, and weighed about 3 grains each. On removing the firm outer coating, all but one were found to be made up of a dark bluish-green substance, which, when pulverized, dissolved readily in water, alcohol and amyl alcohol—completely on boiling—and giving to these solvents a deep blue color. The remaining pill contained a grayish-yellow substance, which burned readily, leaving a small quantity of grayish ash.

The content of one of the first-mentioned pills was dissolved in about 500 c.c. of distilled water. Treated with Weingärtner's reagent, this solution gave a blue-black precipitate and a slightly yellowish filtrate. On treatment with concentrated hydrochloric acid no change was observed. Sodium hydroxid decolorized the solution to a pinkish violet on standing. A solution of chemically pure methylene blue made to the same color as the pill solution, gave exactly the same reactions. The aqueous solution of the dye obtained from the pill, when treated with strong ammonia, became green on heating. The methylene blue solution, when treated in the same manner, was unchanged. Potassium bichromate changed both solutions to a light wine red.

Chloroform removed the color completely from the pill solution, holding it as a light blue. The color was also removed in the same way from the solution of methylene blue, but was almost immediately changed to a yellow. A solution of methylene blue, to which a small amount of chemically pure methyl green had been added, was then treated in the same way. The color was completely taken up by the chloroform and held as a light blue, of the same shade as that obtained from the pill solution, the methyl green having evidently prevented the methylene blue from being decolorized. Chloroform took up the color from a solution of methyl green, but soon decolorized it, the liquid above being colored a wine red. The same solutions were shaken with ether, but without change in any case.

A piece of the solid dye from the pill was treated with concentrated sulphuric acid in a porcelain capsule. The color was changed to a bright grass green, with a yellowish tinge, becoming blue, and finally blue violet on dilution. Solid methylene blue, treated in the same way, gave a bright green, becoming blue and then blue violet on dilution. Solid methyl green gave a dark orange red to carmine, on dilution becoming brown, then olive green, then blue green, and blue.

The solution of the pill and the solution of methylene blue, when treated with picric acid and glycerin, gave a blue-black precipitate and a bluish-green filtrate, of exactly the same shade in both cases. The spectroscopic appearance of the pill solution corresponded exactly to that described above for the solution of methylene blue.

Strips of cotton cloth were then dyed in the solution of the pill, in the solution of methylene blue, and in a solution of methyl violet of approximately the same strength, for the purpose of comparison. After having been allowed to dry in the air over night, the following tests were applied and results obtained as recorded below. The strip dyed in the methylene blue solution was of exactly the same shade as that dyed in the solution of the pill.

TABLE OF COMPARATIVE TESTS.

Treated with.	Pill Solution.	Methylene Blue.	Methyl Violet.
HCl.	Fiber nearly decolorized; liquid blue green.	Fiber nearly decolorized; liquid blue green.	Fiber brownish yellow; liquid amber yellow; violet not restored on dilution.
H_2SO_4.	Fiber and liquid green.	Fiber and liquid green.	Fiber and liquid brownish yellow.
NaOH.	Fiber changed to blue violet.	Fiber changed to blue violet.	Fiber changed to pale reddish violet.
NH_4OH.	Fiber not much changed; somewhat paler.	Fiber not changed.	Fiber changed to red violet; then almost decolorized.
HNO_3.	Green spot.	Green spot.	Green spot surrounded by a bright yellow ring.
Alcohol.	Greenish blue color extracted.	Greenish blue color extracted.	Violet color extracted.

It will be noticed that, as a whole, the tests of the aqueous solution of the material obtained from the pill correspond closely to those given by the aqueous solution of methylene blue, made to the same color. The solid dye treated with sulphuric acid gave a reaction corresponding almost exactly to that of chemically pure methylene blue. There was at first a slight yellowish tinge, resembling the first reaction of malachite or benzaldehyd green, although the end reaction was the same as that of methylene blue. The solid dye obtained by evaporating the various solutions of the pigment, both from the pill and the urine, when treated with strong sulphuric acid, did not give the characteristic bright green color, changing to blue and violet on dilution, given by solid methylene blue; but it was noted that when solutions of pure methylene blue were evaporated to dryness, the residue also failed to respond to this test in the characteristic manner, but behaved the same as the residue from the pill and urine.

The reaction of the pill solution with chloroform is exactly similar to the chloroform reaction of a solution of methylene blue, to which a small amount of methyl green had been added. The possibility of the pill containing small amounts of an anilin green was therefore considered. The dye contained in the pill is entirely soluble in amyl alcohol, and is completely removed from its aqueous solution by this reagent. Amyl alcohol also completely removes it from the urine. It does not change to violet in any of its solutions on heating to 100 degrees C., and consequently, neither the pill nor the urine contains methyl green or its allies, these being insoluble in amyl alcohol, and changing to methyl violet on heating to 100 degrees C. The aqueous solution of the pigment obtained from the urine corresponds very closely in its reactions to the aqueous solution of the pill, the small differences noted being probably due to the presence of urinary salts and coloring matters in the first solution. The spectroscopic examination of the various solutions of the pigment and the reactions to various reagents of the fibers dyed in the same, are both positive for methylene blue. There is, therefore, little doubt that the pills which this patient ingested consisted entirely of a somewhat impure preparation of methylene blue, the impurities consisting very probably of small amounts of basic anilin greens, either malachite or helvetia green.

In regard to the pill which was found to be made up of the yellowish vegetable substance and which can not be told by the external appearance from the pills containing the dye, little can be said, nor is its composition of any great importance in connection with this paper. It is probable that the patient received a larger number of these pills than would be indicated by their proportion in the sample box examined by the writer, that is, that the box examined did not contain a representative sample of the remedy. The pills last described evidently contained the true "remedy," if such it may be called, and were undoubtedly possessed of a mild cathartic action, since the patient states that the remedy had this effect.

A study of the literature shows that blue or green urine is occasionally passed by apparently healthy individuals—especially by children—without there being obtainable any history of the ingestion of an anilin dye. Practitioners unfamiliar with the appearance of methylene blue urine are apt to attribute the urinary pigment to the presence of indigo blue, derived from indican fermentation. Practically all cases, however, of green or blue urine reported in the literature have been due to the ingestion of some anilin dye—in most cases methylene blue. Especially is this the case in those instances in which the patient has complained of no other untoward symptom save the pigmented urine. Cases in children almost invariably result from eating candies highly colored with anilin compounds. Since undertaking this investigation, I have been told of a case in which a child passed a bright red fluorescing urine after having eaten candy colored with eosin.

The question may be raised, why was the urine green in this case, rather than blue? Various workers have shown, however, that the urine is frequently green after a dose of methylene blue, especially the first voided after taking the dye. It was noticed in this case that the urine, after the pigment was removed, was of a bright yellow, and it is not unlikely that this combined with what would otherwise have been a bluish tinge to give rise to the peculiarly brilliant green of this specimen.

In regard to the cause of the aromatic odor of the urine, and of its marked keeping power, nothing definite was ascertained.

COMMENTS ON THE CASE.

The present case is of especial interest from a practical standpoint, inasmuch as it brings to light what seems to be a new method employed by the quack to delude his patient into the belief that the so-called remedy is in reality reaching the kidneys and exerting its remedial effect on them. That this is the sole reason for administering the dye, is evidenced by the fact that the pills containing the substance supposed to be a vegetable purgative are of exactly the same external appearance as those containing the dye.

It is significant that in the case reported by Dun and Douglas, the patient sent to an American firm for a "cure" for chronic rheumatism, and that the urine passed possessed remarkable keeping powers and a peculiar aromatic odor, facts which were both especially noticeable in this case. The directions accompanying the remedy were practically the same as in the present case, and in both instances the medicine was sent as a sample.

It is probable that many cases of blue and green urine will follow the indiscriminate distribution of the above-described "remedy," and will be brought to the notice of physicians, particularly those of southern Michigan and neighboring states. In such cases it will be well to bear in mind the fact that both green and blue urines in nearly every case result from the ingestion of some anilin dye—particularly methylene blue—and to inquire whether the patient has recently taken any proprietary medicine.

A REPORT OF TEN CASES OF PNEUMOTHORAX OCCURRING IN PULMONARY TUBERCULOSIS.

J. W. TRASK, M.D.
Assistant Surgeon U. S. P. H. and M. H. S.
FT. STANTON, N. M.

Pneumothorax as an accident in or complication of pulmonary tuberculosis, occurs usually in but a small percentage of cases. According to West this percentage is 5. Eichhorst found 5 per cent in 390 cases, Gutmann, 4.2 per cent in 2,200, while Weil found 10 per cent in 355 cases. It has been the universal experience that pneumothorax is usually total, that is, that the entire lung collapses and contracts up against the spinal column, thus separating the visceral and parietal pleuræ by a considerable air space, and that partial pneumothorax in which but a part of the lung collapses, and the rest remains in place, due to adhesions or other causes, and but a portion of the pleuræ separate to form a cavity, is much less common. Powell and Whitney state that the total form is the rule, and in Weil's series of 36 cases all but four were of this type. Whitney states in the "20th Century Practice of Medicine," that in partial pneumothorax the symptoms are usually mild, very little general disturbance or discomfort being caused.

Out of 41 deaths occurring at the U. S. Public Health and Marine Hospital Service Sanatorium for Tuberculosis at Fort Stanton during the nine months from Sept. 1, 1902, to May 31, 1903, 9, or 22 per cent., revealed the presence of pneumothorax at autopsy, and at time of writing there is a case of total pneumothorax of the right side still living, but in a very exhausted condition. This makes 10 cases in all during the last 9 months, and of these 5 were total and 5 were partial.

Four of the partial cases ended fatally as the direct result of the accident. In the fifth the lesion was unsuspected during life and was found at autopsy. It had evidently existed for some considerable time. Four of the total cases terminated fatally and one, as previously stated, is still living, but in a very weakened condition.

This large percentage of cases of pneumothorax, which is far in excess of the general rule, the large percentage of partial cases, and the fatality of the partial as well as the total cases, have caused me to consider the series of general interest and their brief report desirable.

CASES.

Case 1.—Aged 25 years, admitted June 23, 1902. Both lungs were found involved as shown by dulness, moist râles, friction sounds, and bronchial breathing. After admission his cough, expectoration, and dyspnea were much lessened. His night-sweats ceased and he gained in weight. The progress of the disease seemed arrested. September 16, two months and twenty-four days after arrival, while walking leisurely a few feet from his tent, he was suddenly seized with a severe pain over the cardiac region and urgent dyspnea. His face became ashy and he showed cyanosis. Beads of perspiration stood out on his forehead.

Examination.—The right side of the thorax was found more prominent than the left, and the intercostal depressions obliterated. On auscultation distant bronchial breathing was heard over the right and large bubbling râles and loud grating friction sounds over the left lung. His condition was continually aggravated by annoying fits of coughing, and he died an hour and a half later from shock.

Autopsy revealed a total pneumothorax of the right side. The right lung was collapsed and contracted up against the spinal column and near its apex was an ulcerated opening 2 mm. in diameter, which connected almost directly with a bronchiole. Tubercles were scattered throughout the lung. The pleural cavity was filled with air and contained a trace of purulent fluid. The left lung was adherent to the thoracic wall throughout, and contained a small cavity in the apex and tubercles scattered throughout both lobes.

Case 2.—Aged 38 years, admitted Oct. 29, 1900. Both lungs were found considerably involved. Shortly after arrival his cough and dyspnea improved and his night-sweats ceased. September 16, 1902, 1 year, 10 months and 18 days after arrival, he had a pulmonary hemorrhage of five fluid ounces. At midnight September 17 he was found dyspneic, with a rapid small compressible pulse. He stated the condition had been coming on for six hours. The condition continued, he became cyanotic, and died September 19, apparently of asphyxia.

Autopsy.—The base of the left lung was found retracted, and the pleural cavity contained air at this point, thus creating a space the size of an orange, which contained a very small amount of serous fluid. No opening through the pleura was found. Both lungs contained tuberculous lesions throughout.

Case 3.—Aged 27 years, admitted Oct. 4, 1901. Both lungs were found extensively involved. For the next few months he seemed to improve. September 4, 1902, his condition was found to have become complicated by a nephritis as evidenced by edema of the face and limbs and the presence of albumin and casts in his urine. His nephritic symptoms became gradually worse and more distressing. During the night of Oct. 5, 1902, one year after arrival, he was found lying on his right side dyspneic and cyanotic with a rapid weak pulse. He complained of something having broken in his right side. His right chest was seen to be bulging. He died of shock an hour and ten minutes later.

Autopsy.—The right half of the thorax was found prominent and hyperresonant. On section the right pleural cavity was found filled with air and its lung collapsed against the spine, except at the apex and base, where it was held by firm adhesions. This lung had a cavity 5 cm. in diameter in the apex and tubercles and areas of infiltration scattered throughout. The heart was drawn considerably to the left. On the right side the upper lobe was adherent to the thoracic wall and contained a large cavity. The lower lobe was studded with tubercles.

Case 4.—Aged 44 years, admitted Sept. 29, 1902. Both lungs were affected throughout. October 8, 9 days after arrival, while sitting quietly on the hospital porch he suddenly became dyspneic, and complained of pain in the left side.

Examination.—The left side of the thorax was found prominent, the intercostal spaces effaced, the respiratory movements hardly noticeable, tactile fremitus absent, the percussion note hyperresonant over the normal lung area, precordia and to the costal margin below; the breath sounds were feeble, distant and bronchial, with an amphoric ring and accompanied by moist amphoric clicks, gurgles and rhonchi. The heart sounds were indistinct on the left, but well heard to the right of the sternum. On the right the respiratory movements were exaggerated. He at first occupied the right lateral decubitus, but on the second day changed to the left. For the next three weeks he improved, although his pulse remained weak. Then he grew gradually weaker and died November 20, one month and twelve days after the onset, of exhaustion.

Autopsy.—On opening the left pleural cavity air escaped with a hiss. The left lung was carnified and compressed against the spine. The pleural cavity was half filled with a greenish-yellow purulent fluid, the heart was drawn to the right and the diaphragm on the left bulged into the abdominal cavity. Both lungs were studded with tubercles throughout and contained infiltrated areas in the apices.

Case 5.—Aged 50 years, admitted Nov. 27, 1902, complaining of cough, copious expectoration, considerable loss in weight, weakness, dyspnea and insomnia. He stated that the dyspnea came on suddenly about six weeks before while aboard his ship and that it was accompanied by pain in the left side and general distress.

Examination.—Emaciation, cyanosis, mucous membranes pale, skin dry and inelastic, and all the symptoms of a complete pyopneumothorax of the left side were present. The succussion splash and *bruit d'airain* were both demonstrated.

Over the right lung the percussion note was dull anteriorly from apex to nipple, crackling râles and rhonchi were heard throughout, and bronchial breathing over the upper lobe. The pulse was small and frequent. His hemoglobin percentage was 70, as found by Tallquist's method. December 2 he had an aggravation of the dyspnea and general distress. For the next five days he was delirious most of the time, and died December 7.

Autopsy.—The postmortem showed edema of extremities, ulcers in ileum and appendix, contracted kidneys, and increase of connective tissue in liver, spleen and kidneys. The diaphragm on the left extended down to the ninth rib in the nipple line and to the tenth rib in the anterior axillary line. On opening the left pleural cavity air escaped with a hissing sound. The lung was collapsed and carnified up against the spine. The pleural cavity contained 1,000 c.c. of greenish yellow purulent fluid. On section a small cavity was found in the apex of the lung. The right lung was adherent to the thoracic wall by many strong adhesions; the upper lobe was almost entirely consolidated and the two lower lobes were studded with tubercles and infiltrated areas. The heart was drawn to the right. It was dilated and filled with currant jelly clots. The mitral valves were sclerotic, contracted and incompetent.

Case 6.—Aged 29 years, admitted July 6, 1902. Both lungs were extensively involved, especially the left. He developed a fistula in ano, which was operated on with chloroform anesthesia Sept. 25, 1902. Jan. 6, 1903, he was seized with sudden severe pain in the left chest and complained that something seemed to have given way on that side. He was dyspneic, pulse was quick, weak and frequent. He was suffering from shock. He then improved for a few days and felt better, especially when sitting up in bed.

Examination.—The left costal margin was more prominent than the right. Vocal fremitus was diminished over the left lung. The epigastrium was tender on palpation. On auscultation amphoric breathing was heard over the left apex and down to the second intercostal space. From the second intercostal space to the nipple were bronchial breathing and crackling and musical râles and friction sounds. From nipple to base there were fair-sized moist râles and the breathing was bronchovesicular. Vocal resonance was present over all parts of left lung. A *to-and-fro shuffling murmur* was heard at the cardiac apex. Pulse was small and of low tension. January 21, he was again seized with a sudden intense pain in the left axilla, accompanied by dyspnea, shock and unconsciousness. The respiration became slow and labored, the pulse was rapid and weak. He occupied the left lateral decubitus. There was absence of respiratory movement over the left lung. The patient became cyanotic and died 45 minutes later of shock.

Autopsy.—The left pleural cavity was found about one-third filled with air. The left lung was collapsed in the middle, but held firmly at the base and apex by adhesions. The pleural cavity, in addition to air, contained a small amount of serous fluid. The lung on section contained a small cavity in each lobe. The right pleuræ were adherent over the greater part of their surface and the right lung was studded with tubercles. On removing the heart the visceral and parietal pericardia were so extensively adherent to each other that they seemed to form a part of the heart wall, leaving thus no pericardial sack at all. The abdomen contained a small amount of a serofibrinous fluid. The liver was nutmeg in appearance and Glisson's capsule was adherent to the diaphragm. The spleen and kidneys showed passive congestion and the loops of the small intestine were adherent to each other.

Case 7.—Aged 37 years, admitted June 2, 1902.

Examination.—This showed considerable involvement of both lungs, and tuberculous ulcers in the larynx. His urine gave the diazo-reaction. He had daily evening pyrexia, with a subnormal morning temperature. During his stay at the sanatorium he had a persistent, troublesome diarrhea, and during the last three months was troubled with emesis. He died Feb. 24, 1903.

Autopsy.—A large cavity was found in the upper lobe of the left lung, and tuberculous infiltration throughout the lower lobe. On the right side the two layers of pleura, the visceral and parietal, were adherent to each other over their entire surface except for an area about 10 cm. in diameter located laterally near the lung apex. At this point the two layers of pleura formed the wall of a cavity the size of an orange. The cavity was filled with pus, and opening into it was an ulcerated perforation 5 mm. in diameter, which connected with a bronchiole. On section the lung was found to contain many small cavities and scattered areas of infiltration. The liver was large, pale and adherent to the diaphragm and parietal peritoneum. The lower jejunum, ileum and cecum contained many tuberculous ulcers.

Case 8.—Aged 32 years, admitted Aug. 19, 1902. Examination showed involvement of an advanced stage in both lungs. During the next few months his general condition improved very considerably. His cough and expectoration became much less. He gained 8 pounds in weight, and was doing so well that his ultimate recovery was expected. March 14, 1903, while walking, he was seized with an attack of dyspnea. He was put immediately to bed and had another similar attack that same evening. For the next few days he continued somewhat dyspneic and cyanotic, with a rapid, weak pulse and some pain on the left side in the region of the nipple.

Examination.—Large moist râles and friction sounds were heard over both lungs. He became gradually weaker, and died March 23, 1903.

Autopsy.—It was found that the lower lobe of the left lung had retracted, forming an air space the size of patient's fist at the base of the left pleural cavity just above the diaphragm. The cavity contained no fluid. The lung was bound to the thoracic wall by many firm adhesions, increasing in number and strength from base to apex. In the apex was found a consolidated mass of firm scar tissue the size of a small apple. Tubercles were scattered throughout both lobes. On the right side the lung was held firmly adherent by old pleuritic adhesions over its entire surface. The upper lobe contained many band-like masses of firm fibrous tissue. The lung contained tubercles scattered throughout. In the heart both ventricles were filled with white clot, and the arch of the aorta contained a few sclerotic patches.

Case 9.—Aged 40 years, admitted Sept. 2, 1902, giving a history of severe cough, copious expectoration, marked dyspnea, and presence of tubercle bacilli in sputum. There was slight dulness in right apex, fine moist râles in both upper lobes and cogwheel respiration over both lungs. His arteries showed considerable sclerosis. During the next few months he appeared to be improving, as far as his pulmonary condition was concerned, but had several epileptic seizures of the grand mal type, and in addition developed a tenderness on pressure and pain on movement over the second and third lumbar vertebræ, which latter was relieved only by wearing a plaster jacket. March 11, 1903, he complained of a severe pain at the right costal margin in the nipple line. This was accompanied by increased dyspnea. On the following day he again complained of a still more severe pain, but this time located at and above the right nipple.

Examination.—Auscultation over this area revealed large bubbling râles and a to-and-fro rush of air as through a small opening. The acute symptoms, which had been violent, subsided, but the patient became gradually weaker, and died March 28.

Autopsy.—The patient showed emaciation. The heart was filled with mixed red and white clots. The right lung was adherent to the thoracic wall throughout except at the base and over the middle third, where the lung was collapsed, thus forming two cavities of irregular shape, each of which contained about 500 cubic cm. of space. These two cavities were filled with pus and connected by a sinuous canal. The upper one connected with a bronchiole by an opening 1 cm. in diameter. On section the lung itself was found to contain a few tubercles scattered throughout the two upper lobes, whereas on the left the lung seemed free from tuberculous changes.

Case 10.—Aged 25 years, admitted Feb. 6, 1903, very weak and in an advanced stage of pulmonary phthisis, both lungs being involved in their entirety and with excavation in their apices. He had chills, night sweats and remittent pyrexia. Then for a few weeks he seemed to improve. He grew stronger, and felt better generally. During the night of April 16 he was seized with a severe pain in the region of the right nipple. He was dyspneic, cyanotic, and had a rapid, weak pulse. His voice was husky and whispering. He lay on the left side.

Examination.—The right side of the thorax was prominent, and the intercostal spaces effaced. Vocal fremitus was all but absent, and over this side there was a full hyperresonant percussion note extending from the third rib to considerably below the normal upper border of liver dulness. The liver could be felt extending two finger breadths below the right costal margin in the nipple line. The heart was displaced to the left. The *bruit d'airain* was present on combined auscultation and percussion. April 19 the patient was very dyspneic and complained of a feeling of tightness on the right side. Fluid was detected by the percussion note and succussion splash, and 500 c.c. were aspirated and the side strapped. This gave him comparative comfort for several days. During May he had three attacks of hemoptysis, and another one on June 6. At present he is in a very weakened condition, which is rendered so precarious by the small amount of serviceable lung left that an early fatal termination seems inevitable.

SUMMARY.

Etiology.—Of the above series 5 had been at the sanatorium for from 2 months and 24 days to 1 year, 10 months and 19 days, and were doing so well prior to the onset of the pneumothorax that they were considered as rapidly approaching the time when they could be considered arrested cases. Leaving out the case of partial pneumothorax discovered postmortem, and the total case which existed at the time of arrival here, and whose exact time and manner of onset are unknown, the accident occurred at a time when the patient was not exerting himself, with the possible exception of the epileptic, who had frequent severe paroxysms of coughing. In each case the accident occurred at a time of comparative rest. Five of the attacks occurred during the night when the patient was in bed, two occurred while leisurely walking, and one while sitting quietly on a shaded porch. In 9 of the cases there was advanced pulmonary disease, and in but 1, the epileptic, was the lung involvement at an early stage. In all cases the extent of the pneumothorax depended on the strength, location and extent of the pleuritic adhesions if present. In the cases of total collapse of the lungs there were either no signs of adhesions or the torn remains showed that they had been few and weak. The extent and location of the partial pneumothoraces depended entirely on the adhesions and not on the site of the perforation. Perforations were not found through old adhesions, nor through the walls of large cavities, but occurred where the adhesions were young and friable or more commonly absent. Air having gained entrance between the two layers of the pleura, the lung collapsed at that point where the adhesion between the visceral and parietal pleuræ was least, namely, where there were either no adhesions at all and the only resistance to be overcome was the negative pressure of the pleural cavity, or else where there were only such adhesions as could be easily torn.

Morbid Anatomy.—Of the 10 cases, as previously stated, 5 were total and 5 partial pneumothorax; 5 were on the left and 5 on the right side. Of the partial cases 2 were at the base, 2 were about midway between apex and base, and 1 consisted of two cavities, 1 at the base and 1 midway between apex and base. Eight of the cases had fluid in the cavity. In 5 it was purulent, in 2 serous and in 1 serofibrinous, the character of the effusion depending on the exciting organisms and the nature of the pleurisy set up. In the cases of total collapse of the lung, and to a lesser degree in the partial, the heart was found drawn toward the sound side, but not rotated appreciably; the diaphragm on the affected side was much lower than normal, and in the cases where the intrathoracic pressure was great, due either to a valvular conformation of the lung perforation or its closure, and the subsequent collection of effusion in the pleural cavity, it bulged downward with its convexity in the abdomen. The liver descended with the diaphragm and was in right-sided cases found extending from one to several finger breadths below the right costal margin.

Symptoms.—The symptoms of onset in the above cases were very similar, and consisted of an initial intense sharp pain on the affected side, accompanied by urgent dyspnea, general distress, cyanosis, and a rapid, weak pulse. The pain was in 5 cases referred to the nipple region, in 1 to the axilla, and in 1 at first to the costal margin in the nipple line, but later to the nipple, while in 1 case no pain was complained of at all. The three latter were in cases of partial pneumothorax. The voice was in most cases affected, being weakened and of a whispering character. The patient in one or two cases felt a distinct breaking as of something giving way in the thorax. As a rule, when first seen after the accident, the patient lay on the sound side, but after a few days when the initial pain had subsided he invariably changed and rested on the affected side.

Contrary to the prevailing opinion and experience that the symptoms of partial pneumothorax are mild and the accident not of serious moment to the patient, our five cases of the above series were as serious and fatal as the total form. Disregarding the one case which was not discovered during life, the subjective symptoms were just as severe and the general distress, dyspnea, cyanosis and shock just as marked in the partial as in the total.

The physical signs differed, depending on whether the pneumothorax was partial or total, and, if partial, on its extent and location. In total collapse of the lung the signs were those invariably found. The affected side was enlarged and the intercostal spaces more or less effaced; the shoulder usually elevated; much diminished respiratory movement, or its entire absence over that side, whereas the sound side made more forcible movements than normally due to the extra work thrown on it. When the lesion was on the left side, the cardiac apex pulsation was absent, and a marked epigastric pulsation present. When the lesion was on the right, the apex beat was found moved to the left. Percussion over the affected side gave a hyperresonant or a truly tympanitic note extending in all directions beyond the normal lung boundaries. Auscultation gave different results, depending on the size and nature, whether open, closed or valvular, of the pleural perforation. Immediately after the accident there was usually heard a distant tubular to-and-fro rush of air which had a decided amphoric tone. Mingled with this were usually heard amphoric tinkling and bubbling râles. Soon after the occurrence of total pneumothorax fluid invariably began to collect in the cavity, due either to fluid escaping from the lung through the perforation or to a pleuritis, or to both, the former causing the latter. After the first two or three days following the onset the acute symptoms of pain and the general distress subsided and the patients felt quite comfortable, aside from the dyspnea.

Prognosis.—The prognosis at this sanatorium has certainly been very unfavorable, all the cases dying as a direct result of the accident, excepting the two previously mentioned, one of which was partial and discovered at autopsy, and the other total, but expected to end fatally at any moment. Of the cases, 3 died from shock, 2 in a little over an hour after the onset, and the third after 15 days, from what seemed a giving way of adhesions and the enlarging of an already partial collapse of the lungs; 2 died of asphyxia, 1 in three, and 1 in nine days, and 3 died from exhaustion in from 17 days to 7 weeks. The cases of partial pneumothorax lived from 3 to 17 days, and the total cases from 1 hour and 10 minutes, to the duration of the case still living at an interval of over two months from the onset.

Conclusions.—From our experience of the last nine months it would seem that pneumothorax is a more common accident here than elsewhere, and that the prognosis is less hopeful. If this be so we would naturally look to the altitude of 6,150 feet as a possible explanation, inasmuch as it requires more air to be respired to oxygenate the blood, and consequently a greater amount of lung or a greater activity of the same amount as would be needed in less elevated regions, and therefore any great disturbance of the respiratory tract such as occurs in pneumothorax is not well borne. But the drawing of conclusions as to why so large a percentage of the deaths at this place have been due to this cause must be deferred until more cases and a larger series can be reviewed.

I desire to thank Dr. P. M. Carrington, at whose instigation this report was written, for placing at my disposal the records of the sanatorium.

HEADACHE FROM NON-SUPPURATIVE INFLAMMATION OF THE ACCESSORY SINUSES OF THE NOSE.

CHARLES M. ROBERTSON, M.A., M.D.
Professor of Rhinology and Laryngology, Chicago Policlinic.
CHICAGO.

Attention has recently been called to headache from disturbance of air pressure in the accessory sinuses of the nose. This disturbance, not so rare as might be supposed, produces all the symptoms of an empyema, except the discharge. The cause of this condition is stated by one author as being "from air pressure in the sinus." It seems to me, however, to be produced by a diminution of air pressure in the sinus. This diminution in pressure is caused by obstruction to the ingress of air to the particular sinus by closure of its natural orifice. For instance, the middle turbinal may be swollen from inflammation; the swollen body obstructs the sinus so that the cavity is shut off from the nasal chambers. The imprisoned air loses its oxygen from absorption by the blood vessels in the mucous membrane of the cavity. As a result of this absorption, the pressure on the mucous membrane is lessened by rarefication of the air contained in the cavity. This causes a swelling of the mucous membrane in the sinus. If the opening becomes patent, the condition subsides, but in cases where the opening remains closed for some time, the cavity is encroached on, 1, by swelling the mucous membrane; 2, by the pouring out into the cavity of lymph, and 3, by the engorgement of the mucous membrane itself by lymph.

The same condition exists here as in non-suppurative inflammation of the ear, caused by occlusion of the eustachian tube. The symptoms vary according to the time the sinus remains closed. The case may present intermittent symptoms from the occasional opening of the sinus by the contraction of the tissues of the middle turbinate. The usual objective signs of empyema are absent. There is no mucopurulent discharge and transillumination gives a negative result.

Case 1.—Mrs. F. J. S. This patient has a nose that appears normal in condition save that there is a hypertrophy of the anterior end of the middle turbinate. She complains of almost constant intense pain between the eyes. It has lasted now for two weeks. She had a similar attack one year ago, which followed "a cold in the head," and was at that time treated by her oculist, who dropped medicine in her eyes and gave her prisms for the relief of exophoria. She subsequently was under the care of an osteopath who treated her till the symptoms subsided. The former attack lasted about three months, until the weather became warmer. At present she complains of photophobia and pain on pressure over the inner angle of the eye. There is no discharge in the nostril, but the middle turbinate is large, red, swollen and slightly myxomatous. Applications of cocain and adrenalin contracted the tissues of the middle turbinate so that a small pledget of cotton could be pressed under it. The turbinate was painted with glycerin and iodin, and the patient experienced relief in an hour after the application. Five treatments, given during a week, resulted in a complete cessation of symptoms. There has been no recurrence of the symptoms since, six months after treatment.

Case 2.—Mrs. A. W. K. had antrum disease 3 years ago and was treated by irrigation through the natural orifice daily for six months, when a cure was effected. There has been no discharge since that time. The present trouble dates from about two months ago. The patient is very nervous, has flushing of the face which lasts about 18 to 24 hours and which is followed by headache which settles over the right antrum. The headaches are similar to those she had while she had antrum disease. Transillumination test shows both sides very clear and of equal brilliancy. The nose is high and narrow. The right middle turbinate hangs well out into the nostril and extends down to the upper edge of the lower one. There is some hypertrophy, most marked on the outer side of the body, toward the hiatus semilunaris. The tissue is red and swollen. It is impossible to pass a probe with a small pledget of cotton under the body without using force. After shrinking the membrane with cocain and adrenalin, the opening of the cavity of the antrum was painted with an astringent pigment and the patient was not seen for two days to note the effect. On the third day she was seen again and said that the pain had disappeared in an hour or two after the first treatment, and that relief lasted 24 hours. Subsequent treatments corroborated these facts. No permanent effect being obtained, at the end of two weeks the anterior end of the middle turbinate was cut away and was followed by absolute and prompt relief.

These cases represent a class of headaches heretofore overlooked, and in one of them the advice of a competent rhinologist was sought, who said it was only imaginary or due to some little cold. It is thus attempted to show that we have non-suppurative inflammations of the accessory sinuses of the nose, as well as in other portions of the body, and that it is possible to relieve such cases by the treatment of the tissues which are the cause of the trouble. Attention to the middle turbinated body is becoming more imperative, as it is the key to the most important part of the nostril.

100 State Street.

HOSPITAL EXPERIENCE NECESSARY FOR LICENSURE—A SUGGESTION IN MEDICAL EDUCATION.

LAWRENCE E. HOLMES, A.B., M.D.
BILTMORE, ASHEVILLE, N. C.

Much has been written on medical education, and the better medical schools are trying to raise the standard by requiring more in the way of general education before allowing one to matriculate, and a more thorough knowledge of medicine, both theoretical and practical, before granting a diploma. The civil authorities in the different states are more or less active in the same line, one state after another in the past few years having made it illegal for a person to practice medicine before he has, ostensibly, shown his fitness for the work, by passing the examination of the licensing board.

These facts show, in brief, that: (1) The standard of educational equipment of the average physician is so low that those best fitted to judge are far from satisfied with it, and (2) these are anxious to improve the present state of affairs. We must admit, however, that the present methods of raising the standard are inadequate, and that the prospects for improvement are not so bright as we would have them.

The requirement of a collegiate degree before admission to a medical school is greatly to be desired, but it will be many years before this will be done by any but a very few of the best schools. State board examinations, though very unsatisfactory and inadequate, are undoubtedly of great benefit, and are a step in the right direction, but are only a short step on what will prove to be a long journey if we follow the same road.

To give an example of the inadequacy of which I speak, let me mention the case of a young man who, after receiving his diploma from a small, almost unheard-of medical school, took the examination of a state board, whose requirements are said to be among the highest. While being "quizzed" by another man who was taking the same examinations, he was asked something about syringomyelia. The young physician hesitated, he evidently knew nothing about it, and then he explained his ignorance by saying that he had seen the name in his text-book, he thought, but that, when they were studying the text-book—not medicine, mind you, but the text-book—they had skipped that subject with several others. He made this statement with the utmost candor, and it probably never occurred to him that there was any difference between the study of medicine and the study of a text-book on the subject. Nevertheless, this man, who evidently had no conception of what a medical education ought to be, passed the examination, was granted a license, and was thus turned loose on the community. This is merely a single case, but undoubtedly there are, every year, many men no better qualified than the one above referred to presenting themselves before examining boards, who, nevertheless, under the present laws in most states, are compelled to grant them licenses to practice, merely because they have passed their theoretical examinations.

The object of the state board of examiners is to prevent men without the necessary requirements from practicing medicine, but in many cases it lamentably fails, even though the requirements of the particular state board may be far above the average. Admitting this to be the case, is there any other practical way of remedying the evil? It seems to me that there is, but, unfortunately, it does not lie in the power of the medical profession, but in that of the legislative authorities, whose duty it is to see that the men whom they pronounce worthy to take in their hands the lives of their fellow beings (for whose benefit and protection they are supposed to enact laws) are worthy of and fitted for the trust.

The method I wish to suggest is this: That the state, in addition to requiring that the applicant pass the state board examination, shall require the applicant to have had at least one year's hospital work before his license is given him. By hospital work I mean that which is afforded by the position of interne in a good hospital. At first sight this may seem impracticable, but it is not likely that it would prove so. It may be said that there are not enough of such hospital positions for every graduate in medicine to obtain one. With the present number of annual graduates this may be true, but it is a well-known fact that the supply of physicians is far in advance of the demand, and if the supply were cut down to meet the demands there would in all probability be positions for all.

Such a legislative provision would be all the more desirable from the fact that it would not only greatly aid in cutting down this far too-plentiful supply and thus aid in reducing so much commercial competition, but, what is better, it would cut off its least capable and desirable portion, for it is well known that the better men in a graduating class, in the better schools, can get hospital positions, though sometimes they may have to wait for a year or so before going on duty; and not only that they can get them, but that, as a rule, they are not satisfied until they do, and do not consider themselves fitted to practice medicine till they have profited by the practical experience which such positions afford. It is, as a general rule, the least capable and most unfit men in any class who are willing to start out in private practice without getting hospital experience—though, of course, there are exceptions to this rule. Undoubtedly such a law would work hardships and injustice in certain cases, but that it would be of the greatest good to the greatest number, which ought to be the fundamental principle in all legislation, there can be no doubt whatsoever.

Possibly it may be said that this suggestion with regard to medical legislation is too Utopian to be practicable in this country. It has not proved so in others, and why should the medical profession in this country be behind that of others in their standards and ideals? In time some such step must be taken, and why is not the time now ripe for it? The only hope of progress is in having high standards and ideals. Let us do all we can to elevate them!

THE PLASTIC SURGERY IN THE UNIVERSITY MATERNITY FOR THE YEAR 1903.*

BARTON COOKE HIRST, M.D.
PHILADELPHIA.

The propriety of repairing the posterior vaginal wall and the pelvic floor after labor by an immediate or intermediate operation is universally conceded. It is curious, therefore, that the other injuries of the genital canal in labor are ignored by the majority of general practitioners and specialists, although they are almost as common and have consequences quite as serious as the so-called "lacerations of the perineum." Indeed, when one considers the indubitable relationship of lacerated cervix to cancer of that region and the discomfort of a cystocele, it is questionable if injuries of the pelvic floor are not of subordinate importance among the three varieties of traumatism to which the genital canal is subjected in labor.

It must appear illogical to the unprejudiced observer to admit that injuries of the pelvic floor should be repaired without fail in the puerperium, but that the other injuries of childbirth, equally disadvantageous to the patient, just as amenable to reparative treatment, may be neglected. I became impressed with the unimpeachable logic of this view some three or more years ago. After desultory attempts at first to apply it in practice, the principle was finally unreservedly adopted. For more than two years not an injury or a pathologic consequence of labor has been allowed to remain uncorrected in the University Maternity. Pelvic inflammations, displacements of the uterus, diastasis of the recti muscles, nephroptosis, injury of the coccyx, inflammations and injuries of the pelvic joints, pelvic and abdominal tumors and diseases complicating childbirth, all receive their appropriate treatment.

It is, however, the purpose of this paper to direct particular attention to our experience and results in the primary and intermediate repair of the cervix and of the anterior vaginal wall, regions which have been strangely neglected not only by physicians in general, but by experts in charge of our large maternities.

THE CERVIX.

During the past year the cervix has been repaired in 53 puerperal patients.[1] The result has been perfectly good in every case. All of these operations were performed after the fifth day, usually at the end of the first week. Previous experience had taught us that an operation on the cervix before the fifth day was too often followed by infection of the endometrium and fever. At the end of a week this is not the case. We postpone, therefore, the repair of the injuries of childbirth for a week, if the cervix is involved. The patient is put on an operating table, and all of her injuries are repaired by a formal operation under anesthesia. I do this in private as well as in hospital practice and with equally good results.

THE ANTERIOR VAGINAL WALL.

Any one who routinely examines the anterior vaginal wall after labor by pressing a forefinger upward in the sulci toward the pubic bone, will be surprised at first to find how frequently the fascia and muscle of the urogenital trigonum are torn through. This is the first step in the pathologic process that ends in a cystocele. The laceration is usually submucous, but whether it is or not, it is as easily and effectually repaired as the analogous injury in the posterior sulci. The operative technic by which this result is secured has been described in another place.[2] The anterior vaginal wall has been repaired in 42 patients during the past year, in each instance with a perfect restoration of its muscular and ligamentous support. We have, I firmly believe, prevented this number of cystoceles which would otherwise have developed in the future.

---

* Read before the Philadelphia County Medical Society.

[1] The cervix was lacerated in 27.8 per cent. of the women delivered; the anterior vaginal wall in 22 per cent., the perineum and pelvic floor in 38.7 per cent.

We may claim, I think, with this record to have demonstrated that all the injuries of childbirth can be successfully repaired during the puerperal convalescence. It is pertinent to inquire, therefore, what valid excuse can be offered for the common practice of neglecting two-thirds of the lacerations of childbirth, while one-third, it is admitted, must be attended to. Why should a woman after labor be only partly patched up? Why should any woman be condemned to years of disability and invalidism as the result of childbirth, and finally be subjected to a secondary operation, when she could be restored to a perfect physical condition during the lying-in period? This is a question which we should seriously consider ourselves before it is forced on us from the outside.

There is no reason at all why this work should not be properly performed in the maternity hospitals of the country. Any institution of the kind not equipped for pelvic and abdominal surgery and not provided with a staff competent to give the patients the attention so many of them require, should obviously either be reformed or suppressed. In private practice, it must be conceded, there are difficulties to overcome, but these difficulties are not insuperable. In the first place, the slipshod methods of the past must give place to a more modern technic. It is impossible either to diagnosticate or to treat the injuries of childbirth properly with the woman across the bed in the first few minutes after delivery, or even, as a recent text-book recommends, before the expulsion of the placenta. The patient should be put on a table with the legs supported as in any other thorough gynecologic examination or vaginal operation. A specialist will have a good portable operating table and a corps of assistants, but any general practitioner can secure a kitchen table and can provide himself with portable leg supports. The only assistant he absolutely requires is an anesthetizer. The necessary instrumental equipment is so simple that it is within any one's means. The aseptic technic necessary for the patient's safety must be familiar to any one fit to practice obstetrics at all.

It has been argued that the adequate repair of the injuries of childbirth would be too much trouble, would not be sufficiently remunerated, would not be tolerated by many patients, and is, therefore, impracticable. The same arguments could be urged against almost any advance in medicine, and if valid, would stop all progress. It is true that some physicians who practice obstetrics to-day could not successfully repair any of the injuries of childbirth, but this will not be true of the immediate future. No medical student leaves the University of Pennsylvania who has not served as assistant in several operations to repair all of the injuries of parturition, and no doubt the other medical colleges in the first rank are giving their students equal advantages. It is exhilarating to think what this improved training can accomplish in preventive medicine. If every woman were given the attention she ought to receive after childbirth, three-fourths of the diseases of women would disappear.

Clinical Reports.

FOUR CASES OF INTERCURRENT ERYSIPELAS IN MELANCHOLIA.

WITH RAPID RECOVERY OR GREAT IMPROVEMENT IN EACH CASE.*

ARTHUR W. ROGERS, M.D.,
WAUWATOSA, WIS.

Introduction.—Recoveries from the acute psychoses as given by different authorities vary all the way from 50 to 80 per cent. The course of treatment in the great majority of these cases is necessarily prolonged, requiring from three to twelve months' time, and calls for the utmost patience and perseverance on the part of the family, the physician and the nurse. However, it occasionally transpires that some intercurrent disease or some unforeseen agency interferes to cut short an attack of mental disease and we have known instances where factors, otherwise considered etiologic, have been responsible for a sudden favorable turn in the disease. The shock following surgical operations has in many predisposed individuals produced insanity. Typhoid fever and other exhausting diseases also play their part in bringing about a state of mental derangement. In some instances shock alone, traumatic, surgical or emotional, is responsible for the development of a favorable mental reaction, while in others toxins circulating in the blood or the reaction due to a febrile movement may be the cause. This so-called reactionary process is the principle applied in thyroid therapy, frequently used in the treatment of some forms of insanity. Thus it is evident that some agencies usually considered causative may also prove curative under certain conditions.

I present the histories of four cases in which this reactionary process was brought about by infection with the streptococcus of erysipelas. All were cases of acute melancholia with profound depression and symptoms promising a protracted course.

Case 1.—A man, 42 years of age, American, married, lumber merchant, gave no history of excesses in any line, but was of a highly neurotic temperament. He had always enjoyed good health and strength aside from an attack of appendicitis about ten years previously. At that time an abscess formed and ruptured into the bowel and left a more or less chronic gastric disturbance. Early in the fall of 1902 he received quite an emotional shock by the sudden death of a 4-year-old daughter, to whom he was very much attached. There soon followed nervous indigestion, insomnia and loss of weight. Then ideas of self-depreciation and marked hypochondriacal obsessions and finally an uncontrollable agitation developed. This patient first came under observation Nov. 12, 1902. At this time a full examination was rendered impossible because of his agitation and his refusal to answer questions intelligently. There was marked insomnia, very little appetite, the tongue was covered with a heavy, dry, yellowish coating and the bowels were constipated. The deep reflexes were all much exaggerated, yet there was no evidence of organic disease. The picture was one of agitated melancholia, with anxious expression, hesitating and disconnected speech, marked confusion of ideas and great impairment of volition. He was unable to dress or feed himself, and passed most of the time walking about his room, fearing that food or water taken into his stomach would produce appendicitis, and frequently asserting that he knew death was impending. November 15 it was noted that he had been growing more agitated and resistive. At this time he gave expression to well-defined delusions of persecution, refusing food from fear of poisoning, would not undress at night because he knew that his enemies would come in and carry him off to the torture chamber, consequently his sleep was much broken. All his symptoms grew more pronounced until he seldom spoke, would do nothing for himself, and required to be fed with the stomach tube. November 21 patient awakened with a well-defined facial erysipelas, beginning on the right side of his face just in front of the ear and in the external canal of the left ear, from which came a seropurulent discharge. At this time the axillary temperature was 100, pulse 95, while there was a slight improvement in his mental condition, so that he took food freely. During the next week the infection spread entirely over his face. The fever remained around 103 F., and at one time reached 105 axillary. Pulse and respiration were rapid. During the height of the fever he was mildly delirious at times, but for the most part exhibited a clearness of ideas and a freedom from depression witnessed at no previous time during his illness. He took nourishment well and extended his co-operation in every respect. There was no return of the temperature twelve days after the erysipelas first appeared, and seventeen days from the time the infection manifested itself he was dressed and walking about his room, partaking heartily of solid food, while his sleep and other physical habits were normal.

---

[2] Text-book on Obstetrics, fourth edition, and Text-book on Diseases of Women.

* Read before the Milwaukee Medical Society.

The most interesting feature of this case was the disappearance of the depression and all other mental symptoms as the fever subsided, so that in fourteen days he passed from a condition of profound and progressive depression, utter confusion of mind and well-defined delusions to one of clear perception, buoyancy of spirits and freedom from delusions. Improvement was uninterrupted, and there was no return of any mental irregularity, and on Jan. 5, 1903, seven weeks after admission, patient was discharged in prime physical health and mentally sound, aside from an unnatural degree of buoyancy.

Case 2.—A man, 64 years of age, with unusually good hereditary influences, married, the father of five healthy children, and a well-to-do farmer, reported having been in excellent health of body and mind for the past thirty-four years. When 30 years of age he had an attack of neurasthenia, lasting only a few weeks. Early in November, 1902, patient began to "feel out of sorts" and complain of fatigue, nervousness and broken sleep. He rapidly grew worse, so that on Jan. 7, 1903, when admitted to the sanitarium, he was very depressed, talked but little, was very restless and uneasy, walking the floor most of the time while awake, rubbing and wringing his hands, saying he was not ill but was suffering for his sins. His delusions related to his unworthiness, loss of property, imaginary poverty, and utter hopelessness of anything being done for him. His physical condition was quite reduced, sleep very broken, appetite poor, but organic changes were absent, aside from considerable arterial thickening. I was called to see this patient early one morning six days after admission. He was profoundly depressed, refusing food, and an erysipelatous rash was spreading over his face. Temperature was 105, pulse 140. During the next four days the temperature ranged from 102 to 104, pulse from 85 to 110. At this time he began showing less opposition to treatment and took nourishment more freely. He also answered questions more promptly and rationally. Eight days after the first appearance of the rash the temperature and pulse were normal. From the inception of the fever motor restlessness practically subsided and never reappeared, and his sleep improved. There was at the same time quite a sudden change for the better in his mental state, so that all opposition disappeared, and he co-operated freely in his treatment. His conversation was more free and rational, and sixteen days from the development of the streptococcus infection the following entry was made in his history: "Patient is improving daily. Had eight hours' natural sleep last night. Eating well. Talks freely and rationally. Is bright and cheerful for the most part; now hopeful and begins to believe that he will recover. Does not show any delusions or other mental irregularities." On March 26, 1903, or ten weeks after admission, he was sufficiently improved to return home.

Case 3.—A man, 49 years old, of a highly neurotic nature, single, and a very successful traveling salesman, came under observation Feb. 6, 1903. Five months previous to admission he found himself growing nervous and irritable and unable to apply himself to business. Insomnia became a source of great anxiety to him, and he slowly drifted into a state of melancholia, with many and rapidly changing delusions of a hypochondriacal order. He was positive that nothing could be done for him. His waking hours were full of horrible fears, and his few hours of sleep disturbed by terrifying nightmare. If he were left alone a few minutes he became so alarmed as to cry out for help. Physically he was much reduced. Nineteen days subsequent to his admission he developed facial erysipelas, with a temperature of 103 and a pulse of 130. The eruption, temperature and other somatic symptoms ran a course of only five days. Coincident with the first rise of temperature, there was an improvement in his mental state, and the notes state that five days after the fever subsided he was normal, less nervous, sleeping better and appeared much less anxious about himself, and patient stated he was feeling better in every way. At no time subsequent to this infection was there any return of his delusions, although at times he became nervous and anxious. In four weeks he returned home and gradually began to take up his duties, and is quite well to-day.

These three cases demonstrate the almost miraculously sudden physical improvement and rapid melting away of delusions not infrequently witnessed by those coming in constant contact with the insane where some intercurrent disease or severe shock occurs. This is, however, more frequently the case in the reaction following the infection with the germ of erysipelas. None of these three cases has suffered from a return of their mental symptoms during the past twelve months. I had the opportunity, however, to observe one more psychosis complicated with erysipelas where the results were not so permanent but none the less sudden and pronounced.

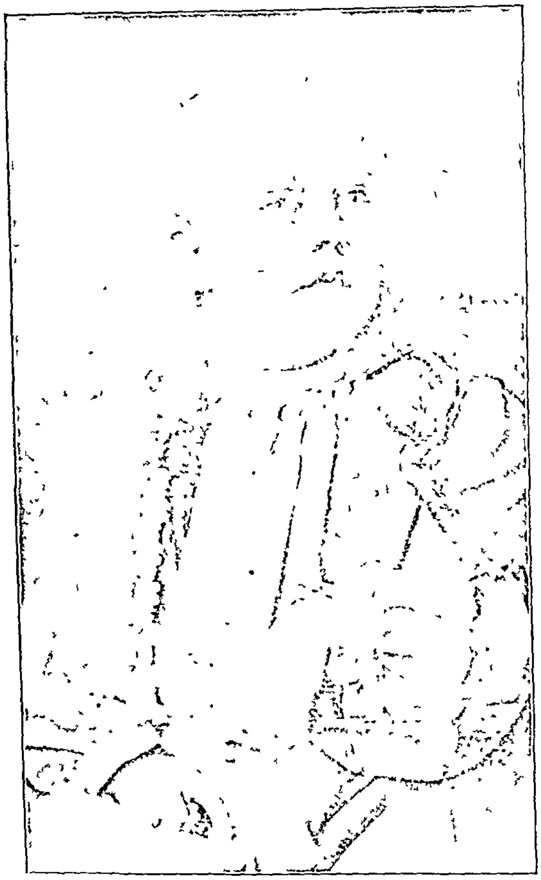
Case 4.—A man, 45 years of age, was suffering from profound melancholia. Insomnia, motor agitation and complete refusal of food were present along with delusions of persecution and loss of property. In this condition facial erysipelas developed, accompanied by a run of fever lasting a week, temperature never going above 100.5. Patient began to improve in every way as the temperature developed. His physical habits and functions became regular. There was a rapid mental clearing up, but he never abandoned the delusion that he was a ruined man financially. Four weeks later he began to grow more restless, sleeping poorly, and was more or less under the control of his delusive ideas. During the next eight weeks his condition remained stationary, but at no time during the past several months has he returned to the profound depression and confusion preceding the infection above named.

CIRSOID ANEURISM OF THE BRANCHES OF THE INTERNAL CAROTID AND BASILAR ARTERIES.

GEORGE H. HEITMULLER, M.D.
Medical Inspector of Public Schools.
WASHINGTON, D. C.

I am indebted to Dr. Charles Montgomery for the privilege of reporting this case.

The patient, M. M., aged 13, has a negative family history. She presents a tumor over the right orbit which is said to have appeared a short time after birth as a growth the size of a hazel nut, whereas it now extends midway to the occiput. The tumor is pale in color, of a doughy consistency, and is composed of dilated terminal branches of the ophthalmic artery. There is absence of hair over the tumor. The eye projects forward, downward and outward. The conjunctiva of the upper lid and of the inner and outer angles of the eye is thickened by distended blood vessels. The cheeks show dilated capillaries near the nose. Dilated vessels are not seen elsewhere. There does *not appear* to be any weakness in the walls of the arteries, as was shown by the prompt arrest of hemorrhage following the extraction of a right upper molar. This operation gave the patient great pain, showing that the fifth nerve was not affected. The fingers of the left hand are flexed and can exert some pressure, but less than can those of the right, and when this pressure is exerted a tremor develops. This is shown in the photograph by the blurred image of the hand which held the pencil, while the right hand was perfectly steady. The extensors are paralyzed; she straightens her fingers with the other hand, but they immediately *return* to the flexed condition. The left leg shows the same condition, the extensors are paralyzed, the flexors are in slight spasm, and in walking there is a spastic gait, the toes catching the ground. *The spasm of the flexors* has developed gradually during the last six years. The skin of the left side is hyperesthetic. The right ear is deaf, the right nostril has lost the sense of smell, the right eye is blind and its pupil smaller than that of the left, but acts consensually, though sluggishly, with the left. All the external muscles of the right eye excepting the external rectus and the superior oblique are paralyzed, as is evidenced by the inability to move the eye up and in beyond the median line. The upper lid can be raised slightly, but that is evidently due to the action of the occipitofrontalis (i. e., paralysis *of the third nerve with the exception of* the fibers supplying the sphincter of the pupil and the ciliary muscle; these also do not functionate properly, as is evidenced by sluggish pupillary reaction).



Ophthalmoscopic examination shows the media perfectly clear. The optic nerve can not be seen. The entire background shows one mass of closely packed distended and tortuous arteries which have lost the central reflex band. At no place in the retina is there the smallest area free from vessels, and arteries can not be distinguished from veins. The left eye retains the power of all the muscles, but the pupil does not react when light is thrown into the right eye. There is entire absence of the left side of the field of vision and the right side is contracted to within ten or fifteen degrees of the fixation point.

The left ear and the left nostril are normal.

The tongue deviates from the median line when protruded and has lost the sense of taste on the right half. The patient has a very good memory and recites a piece of poetry of about forty verses without hesitation, but when speaking in ordinary conversation there has been of late a hesitancy in speech.

From the symptoms it will appear that the right olfactory nerve and the right optic nerve and commissure are subjected to pressure, and this is produced by the dilatation of the anterior *cerebral* and right ophthalmic arteries; the right third nerve and the crus cerebri are likewise subjected to pressure, and this is produced by the dilatation of the posterior communicating, posterior cerebellar and subcerebellar arteries. The pressure on the eighth and ninth nerves is produced by the dilatation of the anterior cerebellar, a branch of the basilar artery. As the basilar is formed by the two vertebral arteries, and *the right anterior cerebral receives* blood directly from the left anterior cerebral through the anterior communicating artery, ligating the right internal carotid and the right vertebral would be of no avail. I look forward to some amelioration of the conditions when menstruation is established.

ATTEMPT AT SUICIDE BY DRIVING NAIL INTO THE BRAIN.

G. F. POPE, M.D.
BATTLE MOUNTAIN, NEVADA.

J. F. B., a native of England, aged 43 years, who was employed on the Nevada Central Railroad as a section laborer, had been on a drunk for two weeks. I was called by the jailer to see him, as he had refused to take any nourishment for three days. Pulse, 80; temperature, 99; bowels constipated. I advised *nourishment* by the *stomach tube; this* measure was successful, and soon he began to take regular meals. I was told that he had talked of committing suicide by driving a nail into his head.

I was asked to see him again ten days later and found him somewhat drowsy and unwilling to answer questions unless urged to very forcibly. Pulse, 86; temperature, 102. He referred what pain he had to the head, and on examination I found the head of a nail buried in the scalp six and one-half inches back of the nasal eminence in the suture between the two parietal bones. He was removed to the nearest hotel, and after an hour's questioning he admitted having driven a nail into his head in attempting suicide.

Under chloroform I extracted a three-inch wire nail, which had been sharpened for the occasion. Pus escaped from the nail hole, so I laid back a flap of the scalp and trephined the skull over the nail hole. On removing the button of bone, *still* more pus escaped, so I irrigated the track of the nail with sterilized water and with peroxid of hydrogen. By gently probing I traced the course of the nail down between the hemispheres of the brain into the great longitudinal fissure. A three-and-a-half *inch drainage* tube was insinuated into the course the nail had taken and a bichlorid dressing applied.

The wound was irrigated each day with peroxid of hydrogen and with sterilized water. The tube was shortened from time to time, the wound was well healed in two weeks, and the man was committed to the state asylum at Reno.

Coffee Gelatin vs. Coffee Infusion.—The London *Lancet* says: "A clear coffee gelatin after dinner is every bit as good as the hot infusion, while it is free from some of the drawbacks of the latter." Is this true for the person whose only purpose in drinking coffee is to have a hot drink to "warm up his stomach"? The *Lancet* calls gelatin an excellent vehicle for coffee, especially *because it nullifies the astringent* principles. Gelatin in the form of jelly is cooling, assuages thirst, is soothing, and has a tendency to absorb any excessive acidity of the stomach. This indicates where it will be of value.

THE BIOLOGY OF CANCER.

Cancer is a subject that requires the utilization of every possible source of knowledge for the solution of its problems. It is fortunate that it is a disorder not confined to our species, but that in many ways it can be studied to advantage in the lower animals. This probably has been too little recognized in the past, but its fundamental significance was early seen by the workers in the British Cancer Research Fund. In an important paper recently published,[1] the general superintendent and director of the cancer research laboratory, Dr. E. F. Bashford, with the co-operation of Dr. J. A. Murray, reports the results of the investigations during the past year. They find that cancer growths are by no means infrequent in almost all orders of vertebrates, and in their general features are the same in all, notwithstanding the great diversity of conditions and environment. The very large number observed in domestic animals indicates very clearly, they say, that the malignancy of the growths is recognized according to the ease with which the animals can be examined and the length of time they are kept under observation. Malignant new growths are frequent according as the animals are frequently examined, and are only unrecorded in the species that are difficult to observe or that do not reach old age in sufficient numbers.

A few weeks ago, in a paper presented to the Royal Society, Farmer, Moore and Walker reported that the mitoses of cancer growths in man in part closely resemble or are identical with those of the reproductive cells. From their observations the authors concluded that malignant new growths were virtually reproductive tissue arising in abnormal situations and independent in growth like that of certain organs, such as the testis in the mammalian body. This peculiar sequence of the reproductive type of mitoses in cancers was present in all malignant growths they examined, but absent in the benign.

Drs. Bashford and Murray have had opportunity of examining the specimens reported on by these authors, and have carried the investigation still further into the lower animals with the result of fully confirming their statements as to the facts. They note the following points as of great importance: "A complicated sequence of cell changes has been found to be characteristic of carcinoma and sarcoma alike. The sequence is the same as that which initiates the origin of the sexual generation in plants from the asexual and [which] is terminal in the history of the sexual cells in animals." They further note the fact that not all the cells of malignant new growth undergo this reducing division. A certain number follow the type of mitoses of the tissues among which the growths arise. In secondary growths the usual somatic mitoses occur in the growing margin, which is also a feature in the growth of the transplanted metastatic cancer.

The transmission of cancer from man to animals or from one species of animals to another, has not been successfully performed, but it has been well established that cancer growths can be transferred from one animal to another of the same species. Professor Jensen of Copenhagen, who has done most in this direction, has placed some of his material at the disposal of the Cancer Research Fund, and Bashford and Murray have been able to confirm by experiments his observations. They find that the transplantation is identical in its processes with metastasis as it occurs in individuals providing the tumor. The earliest mitoses observed are of the somatic type. The process is in no sense an infection, the tissue of the new host not participating in the formation of new parenchyma; hence, the authors agree with Jensen and not with Borrel, who considered the results due to the agency of a cancer virus. The immense proliferation of the growth thus transplanted is one of its striking features, and indicates the possibilities of cancer dissemination. The phenomena of the experimental transmission of carcinoma show, they say, that we must distinguish between the problem of genesis of cancer and that of the condition which permits of its continued existence. The phenomena of cell division resembling those of the ordinary reproductive tissues may help to explain the nature of the great power of multiplication, but give no help as to the problem of cancer genesis. These phenomena, however, give indications of the character of the processes. The wide distribution of malignant growths and the possibilities in this regard not yet ascertained indicate that the cause of cancer is to be sought in a disturbance of those phenomena of reproduction and cell life that are common in the forms in which it occurs. Observations on animals—and these agree with the clinical facts in man—show that malignant new growths are always local in their origin, and of themselves produce no evident constitutional disturbance. There is an absence of specific symptoms, and the evident finding that cancer is an irregular and localized manifestation of normal processes in the life cycle of the organism probably explains why malignant new growths and their secondary disturbances have no specific symptomatology.

The suggestiveness of the facts here brought out, especially those noted by Farmer, Moore and Walker that cancer cells develop mitoses identical with those of reproductive cells, is obvious. They are perhaps a little too suggestive, and may lead to deductions that are not as yet warranted. Attention is called to this point in a note added to the article of Drs. Bashford and Murray, who remark that their utterances have been misconstrued and conclusions attributed to them that have been drawn by others. The cells, they say, that have undergone the reducing division are not responsible for the invasion of the surrounding tissues nor for the production of metastases; for both of these the somatic dividing cells are responsible. Nor do the number of heterotype or reproductive mitoses in the cells have any relation apparently to the degree of malignancy; their absence is only presumptive evidence of the benign character of the tumor. They postulate nothing as to the future of these cells, though they believe them to be the terminal stage in the life cycle of cancer cells as in the sexual cells in animals. The local origin and the expansive and infiltrating growth is really the criterion of malignancy, and stamps it as belonging to a new cycle comparable in its entirety to the whole organism which it is invading rather than to any one of its tissues, reproductive or otherwise. The article is one that will undoubtedly attract considerable attention and be fruitful of future work in this particular line. The problems of cancer are yet very far from solution, but every step like this is an aid to their elucidation.

PHYSICAL CHEMISTRY AND SERUM THERAPY.

The subject of serum therapy is developing rapidly into such a complicated affair that few physicians have time or patience to attempt to master it. It certainly is a hopeless task for those engaged in ordinary practice. Only a few specialists pretend to know the various theories in all their phases, and to keep up not only with the great mass of facts daily accumulating, but also with the modifications of the theories which these new facts continually demand. No wonder we occasionally hear severe criticism of Ehrlich's theory, for instance, as regards its extreme complexity and the absurdity of some of its conceptions. Perhaps too often it is from those who have not the patience, or possibly the prerequisite knowledge to follow out the intricacies of the hypothesis, and who, for that reason, should not be heard. However absurd may appear some of the assumptions, no one can object to the theory as a working hypothesis. More than this no one claims for it. And until we get something better, it will continue to direct and suggest thought in the future as it has done for several years past. However, it is clear that it is only a question of time when the theory must give way to something more fundamental. It deals with chemical substances and chemical and physical processes; therefore, ultimately it must be interpreted in terms of chemistry and physics. It seems, then, that the vast nomenclature which has arisen in connection with this work must largely be supplanted by chemical and physical terms as soon as we have a sufficient understanding of these substances to apply them.

Of extreme importance is the recent work of Kyes, already editorially commented on in THE JOURNAL, in the way of placing this whole conception on a chemical basis. How much simpler the whole subject becomes when we know that a definite chemical substance—lecithin—can act as a complement, and also that a toxin, which we are accustomed to look on as a complex organic substance, can be isolated and dealt with in pure crystalline form. This work is certainly extremely encouraging for the simplification of our conceptions of serum therapy.

Of equal interest and importance is the work of Arrhenius and Madsen[1] in purely physicochemical lines. Perhaps the medical profession should be congratulated on having the interest and thought of such a genius as Arrhenius directed along this line. Arrhenius is the noted physical chemist in Stockholm. We are already indebted to him for his great work in electrochemistry. It was he who, in 1887, first formulated that important and far-reaching theory of electrolytic dissociation. Through the brilliant work by van t'Hoff on the analogy of dilute solutions and gases and their relation to osmotic pressure, and also through the work of Raoult on the depression of the freezing point, Arrhenius was able from his observations on electrical conductivity to formulate this theory. It certainly is one of the most noteworthy generalizations in science in the nineteenth century. It is only recently also that he has accomplished much for science through the application of the conception of ions and electrons in the explanation of meteorologic phenomena.

His work in conjunction with Madsen in serum therapy bids fair to be of the same revolutionizing character that it has been in other fields. The problem here is the application of physical chemistry to serum therapy. They have shown, especially in their work with tetanolysin, that the same laws govern the reactions occurring between toxin and antitoxin as occur in ordinary chemical processes. The law of mass action prevails here as in other reactions. By this law is simply meant that the rate or velocity of a chemical reaction is proportional to the concentration of the substances reacting, i. e., to the product of the concentrations. This can be represented by the simple formula $V=KC_1C_2$ where V is the velocity, C_1 and C_2 the concentration of the reacting substances and K a constant for a given temperature, pressure, etc. The concentration is often spoken of as the active mass, and refers to the amount of substance dissolved in unit volume. In the case of solids, the concentration or active mass is always constant, and so the active mass is entirely independent of the absolute quantity of solid. As a simple illustration of the laws of mass action, we may refer to the inversion of cane sugar by an acid. If a certain quantity of a 10 per cent. solution of cane sugar is inverted in a unit of time, say one minute, then in a 5 per cent. solution of sugar only one-half as much sugar would be inverted in the same time and by the same quantity of the acid. The velocity of the reaction is only one-half as great in the latter case, therefore proportional to the concentration. It is to be noted, however, that the same time would be required in both cases for complete inversion. Now chemical equilibrium is established when the velocity of the reaction occurring in one direction of a chemical process equals the velocity of the reaction occurring in the opposite direction. Thus the relation of chemical equilibrium to mass action is made apparent.

---

[1] Zeitschr. f. physikal. Chemie, 1903, 44, 1.

The work of Arrhenius and Madsen shows that such laws as the above can be applied to such processes as the neutralization of toxin by antitoxin, hemolysis, etc. For example, the amboceptor and complement in combining, do so in such a way that they can be represented by the following equation: (amboceptor) $\times$ (complement) $= K \times$ (hemolysin) where K is a constant for same conditions of temperature, etc. In general, we may conclude, then, that the laws of chemistry and physics hold here as elsewhere. No one probably ever doubted the fact, but the significant point is that the demonstration is at hand.

So here, again, we have a whole new field opened up to the investigator; and certainly it seems to be a most fruitful one for important discoveries. Not only will new facts be discovered, but new interpretations may be given to facts already known which often means as much as the discovery of new ones. We have another illustration of the importance of physics, chemistry and mathematics to the biologist.

SECRETARY TAFT AND THE ARMY MEDICAL DEPARTMENT.

One of the first official acts of Secretary Taft can not but be highly gratifying to every member of the medical profession. It seems that, forced by certain incongruities in the present plan of organization of the Army Medical Department, a bill was drawn by which it was proposed, among other things, to increase the number of surgeons of the higher military rank and to provide for a reserve corps to be made available in time of war.

The original draft of this bill went in the ordinary course, before the General Staff for consideration and report. This General Staff is a highly useful body, created for advisory purposes, and presumed to be made up of representatives of the various branches of the service. It consists of forty-two members, four of whom, for instance, are general officers, twenty-two are line officers, five are engineers, while others are representatives of the Quartermaster's Department, the Signal Corps, the Artillery and other branches of the service. The Medical Department, alone, is without representation. Yet this General Staff, or at least the third division of it, made up of a representative from the Adjutant-General's Department, one from the Ordnance, two from the Artillery and one from the Signal Corps, considers and passes on the most intricate technical questions connected with the Medical Department, and, in the present instance, was called on to sit in judgment on the proposed measures for the reorganization of the medical staff. Naturally enough, several of the recommendations of the Surgeon General, notably the one asking for an increased number of surgeons of the higher military grades, were not indorsed. The Surgeon General, however, so it seems from the published correspondence, insisted on his point. The then secretary, Mr. Root, sent the draft back to the General Staff. The chief of staff then returned it, insisting on the previous dissent and filing an argument in support of the attitude of the General Staff.

The bill was in this condition when Secretary Taft took charge of the war office. His manner of disposing of the question shows that Secretary Taft is still Judge Taft, whatever may be his title. Thus, in his letter of transmittal to the chairman of the Committee on Military Affairs of the House, published in full in last week's issue of The Journal, he states, among other things:

> I have, however, carefully read the arguments of the Surgeon General and the statement of the third division of the General Staff, and also of the chief of staff, and I am bound to say that it seems to me that the arguments of the Surgeon General substantially outweigh those advanced by the chief of staff.

The recommendations of the Surgeon General were, accordingly, substantially concurred in, and in that condition the bill is now before Congress. This circumstance is mentioned at this time to show that the Secretary of War is, in fact, the head of his department; that he has a mind of his own and a judicial mind at that; and, furthermore, that the necessities of the medical service will receive intelligent and just consideration at his hands. It is the duty of the medical profession to make known its appreciation of his fairmindedness, which, unfortunately, has not always prevailed in the office now occupied by Secretary Taft.

THE DEVELOPMENT OF HEMOLYMPH NODES IN ADIPOSE TISSUE.

It is well known that under pathologic conditions new lymphadenoid tissue may arise either from pre-existing lymphadenoid tissue, from fat tissue as well as in fibrillated connective tissue, e. g., in the mucous and submucous coats of the intestines. Bayer laid special stress on the new formation of lymph nodes in fat tissue, as, for instance, in the neck and in the axilla, both being regions of especial interest to surgeons on account of the frequency of tuberculosis and carcinoma of the cervical and axillary glands.

In the course of his valuable studies of the hemolymph nodes, i. e., lymph glands with distinct blood sinuses, Warthin became aware of a close relationship between these glands also and adipose tissue, and in a recent paper[1] he discusses the histogenetic aspects of this relationship. In the first place, he emphasizes the lability of lymphoid tissue in general, which, in the case of the deeper lymph glands, shows itself especially in the marked variability in number, size and structure, as well as location. This variability is apparently even more pronounced as regards the hemolymph nodes in man, sheep and goats. In pregnancy and lactation, the axillary glands increase in size and apparently also in number, due, it seems, to new formation of lymphoid tissue in the axillary fat, as described by Bayer and Zehnder in regeneration of lymph glands. When lymph glands in any region become the seat of advanced disease, such as metastatic carcinoma, or are removed from the body by dissection, new nodes soon appear. Here, no doubt, is the reason that in regional lymphatic carcinoma the number of invaded glands so often seems to exceed the number of glands usually regarded as normal for the region in question. The new nodes, in part, arise in undeveloped nodes or collections of lymphoid cells that have the power of compensatory growth, but also it is thought wholly anew in the fat tissue. This progressive process finds its opposite in the fatty metaplasia of lymph glands in old age.

The hemolymph glands occupy similar relations to fat. Warthin describes a transformation in the embryo of the primitive fat organs into hemolymph nodes, in the course of which lymphoid cells appear along the capillaries, gradually increasing in number and assuming a characteristic arrangement. The origin of these lymphoid cells is not as yet clear. Lumps of fat tissue inclosing hemolymph nodes assume a brownish color in formalin—a means to help their recognition. In pernicious anemia and in splenic anemia, Warthin finds abundant evidence of new formation of hemolymph nodes, showing that under certain pathologic conditions the "stimuli" necessary for this evolution in fat become operative. Splenectomy in goats and sheep is also followed by the appearance of new hemolymph nodes in adipose tissue, even in those parts where normally they do not occur, as in the subcutaneous fat and along peripheral lymphatics. Many of the nodules described by earlier observers as new splenic tissue in splenectomized animals, appear to have been hemolymph glands. The exact causes and mechanism at work when new lymph nodes arise in fat are not understood. Lymph stasis in case of ordinary lymph nodes, or blood stasis in the case of the hemolymph nodes, is regarded as the earliest change in the fat lobules. Later the dilated lymphatics become lymph sinuses and the dilated blood capillaries blood sinuses, but the fundamental causes of this primary dilatation have not been worked out.

ADMINISTRATION OF THE ARMY MEDICAL DEPARTMENT.

The *British Medical Journal,* February 13, contains a leading editorial and a resolution by the British Medical Association which have a singular appropriateness to present conditions in the United States. The Boer War revealed defects in the organization of the British War Department very similar to those which the Spanish War brought to light in our own, and the proposed remedy for inco-ordinated bureaucratic administration is an army council corresponding to our new General Staff. It appears that on this army council, as on our General Staff, one of the most important and in number the greatest of all the staff departments, the medical, is not represented. Against this ill-advised and fatuous omission the British Medical Association protests in dignified and forcible terms, and the *British Medical Journal* points out that the dearly bought lessons of the Boer War are being already forgotten or ignored.

The parallel in our own service is complete. The function of our Army General Staff is to prepare plans for the national defense and to study all questions connected with the efficiency of the Army. Certain members of it are detailed for duty on the staffs of general officers, but as only a few are called on to perform executive duties, there is nothing in the law or organization of the General Staff which stands in the way of medical officers thereon. The Medical Corps is by far the largest of all the staff departments, constituting one-twelfth of the commissioned strength of the Army. It nearly equals in numbers the eight other staff departments which together contribute eleven out of the forty-two members of the General Staff. In the sanitary supervision of the Army and the examination of its recruits, as well as in the care of the sick and wounded, its efficiency is closely connected with that of the Army. It has an enlisted force of three thousand hospital corps men. In time of war it has administrative problems, which, in complexity and magnitude, are exceeded by those of no other staff department. And yet, in the working out of these problems and the study of questions of its own organization, the Medical Department has no voice. Matters pertaining to the organization, equipment and training of the Medical Department are considered and determined by a section of the General Staff composed of two officers of artillery, one of cavalry and one of infantry. All other matters pertaining to the Medical Department, no matter how complicated, technical and special they may be, are in the hands of the third division of the General Staff, the composition of which is an officer of the Adjutant-General's Department, one of the Ordnance, two of the Artillery and one of the Signal Corps.

The situation suggests laughter, and yet it is serious and should engage the prompt attention of the medical profession in this country as it has in England.

---

[1] Proceedings of the Pathological Society of Philadelphia, 1903, vi, [illegible]

PRINTERS AND EDITORS.

That Chicago publications are *not the only ones* that are embarrassed sometimes by strikes in the mechanical department, is evidenced by the apology for lateness of issue which the *Boston Medical and Surgical Journal* gives in a recent number. Our contemporary has our sympathy, as has also the *Journal of Medical Research*, which likewise has the misfortune (we use the word only in its application to the existing delay) to be issued in Boston. A card announces that the *Index Medicus* is also a sufferer, the annual indexes for 1903 being still unfinished. We wish our Boston friends speedy release from their handicap. Our sympathy is born of experience.

THE NEXT SESSION OF THE ASSOCIATION.

Among the sections of the United States which have in mind an endeavor to secure the 1905 session of the American Medical Association is that which includes the states of Washington and Oregon. According to an editorial in the *Medical Sentinel*, the profession of the far northwest is actively at work to secure the session for either Seattle or Portland. They are mindful of the distance from the majority of the members and of the requirements to entertain such a large body, and it may be premature for us to call attention to the matter. We do so simply to give information to others. The Association last met on the Pacific coast in 1894, and in the general rotation of geographical distribution of the place of session, the Pacific coast will doubtless be the place of session before many years pass by. The Pacific coast is a delightful place to visit, and if one may judge from the attitude of the profession of the north coast, the American Medical Association would be warmly welcomed and heartily entertained. But Oregon and Washington are a long, long way off, and the railroad fare would be a great big item, and the time spent in coming and going is not the least of the objections.

HOSPITAL CARS FOR TUBERCULOUS TRAVELERS.

The plan which it is announced that the Santa Fe Railroad will adopt of operating hospital cars especially for consumptives, would be a good idea if it were more practicable. It is said that the company finds it something of a hardship to have to disinfect its cars after known cases of consumption have used them, and it therefore proposes to isolate consumptives and bar them from the conveyances used by others. That this will work a hardship in some cases goes without saying, but it may perhaps be advisable. There is, however, a practical objection which the company can not meet, and that is, unless they have some inspection methods and even a tuberculin test beforehand, the hospital cars will be occupied only by the most advanced cases, while the milder forms, which may be equally communicable, will pass unrecognized in the regular Pullman coaches. Probably one person in every two is at one time or other in his life affected with tuberculosis and may be capable of conveying it to others. Though the chances of this are probably greatly exaggerated, it would be a satisfaction to many to know that consumptives are not allowed to ride on Pullman cars. We must repeat that we have doubts as to the effectiveness of the proposed arrangement; what would be more practical and more humane would be a more sanitary, if less gaudy, car, even though this would necessitate the elimination of the unnecessary upholstery and other germ-carrying furnishings.

LEGISLATION FOR FREAKS AND FRAUDS.

Every little while some member of a state legislature furnishes amusement by introducing a freak bill as evidence of his mental aberration, incompetency or idiosyncrasy. One of the latest is a bill introduced into the Iowa legislature to legalize a new school of healing to be called "psychiropathy," apparently a sort of catch-all, to take in everything except the schools of medicine that are already recognized by the law. Eddyism, Dowieism, vitopathy, sarcic psychology—whatever that is—chiropractic, hypnotism, etc., are all lumped together with the Swedish movement cure, and hydropathic treatment under this general designation of psychiropathy. The results would, of course, be to let in every kind of fraud, quackery and delusion that can creep in under this comprehensive head. We have too much confidence in the good sense of the Iowa legislators to think that the bill will go through. There is even a suggestion that it is introduced as a sort of sarcasm, with no idea of its passing. It is well to be on the lookout for everything of this kind, however, for there is no telling in what way the humbugs will show up, and legislative sessions are too often perilous times for good government.

THE DISINFECTION OF PAPER MONEY.

A proposition has been made that banking institutions disinfect all paper currency which passes through their hands. This proposition is made in all seriousness, and is worthy of commendation. If there is any value in disinfection, and if it is worth while to attempt to avoid contagion, it seems a little remarkable that we regularly and willingly undergo the dangers from a medium that is a good contagion carrier, that passes through all kinds of hands, and that consequently favors the spread of disease. No sanitarian would refuse a ten-dollar bill, however tattered and infected, not even from the hands of one whose sanitary condition is obviously unwholesome; and who can tell through whose hands it passed before? It is not too much to say that the fight against tuberculosis and other infectious diseases will result only in partial success if the danger from paper currency is not recognized. Of course, even though the banks disinfect all such currency, there will still be the danger from the interchange among individuals. At the same time, the disinfection by wholesale, if we may so put it, by the banks will surely do much good. The expense will be very small, and the evil possibilities that will be lessened are hardly calculable.

THE DANGERS OF THE BATH.

In the onward march of medical progress there come frequent warnings against established customs, and we are admonished that this or that habit is exceedingly dangerous, and we accordingly mend our ways. These behests of science not infrequently meet remonstrance, in spite of the columns of statistics, bacteriologic slides and case histories. For some time we have boiled the water that we drink, now we must boil the water in which we bathe. An Indian confrère[1] warns against the careless practice of bathing in typhoid-laden water, and declares that access to the mucous cavities during immersion is comparatively easy to the little bacteria. To treat the matter seriously, here is a real danger, much greater in India, perhaps, and wherever water is badly infected, but a present danger in all typhoid-infected water. Just how much possibility of infection there may be in the entrance of a few ounces of water into mucous cavities will depend on the virulence of the germs and the resistance of the system. If we approve the warnings to wash raw vegetables in boiled water, to use pure ice, to brush the teeth in boiled water, it naturally follows that to be perfectly consistent and safe one must bathe in water that has been boiled.

THE PANAMA CANAL COMMISSION'S SANITATION PROBLEM.

For reasons that are not entirely within our cognizance, President Roosevelt has not granted the petition of the medical profession that he would appoint a medical sanitarian on the Panama Canal Commission. Without wishing to criticise, we naturally regret this, but we still trust that the sanitary necessities of the case will be provided for—not superficially but efficiently. The history of the earlier work on the Panama isthmus is enough to convince anyone that the first question of all is that of sanitation. The mortality may be enormous, and the responsibility therefore appalling. What can be done now that the commission is fully appointed is to insure that a hygienic administration under a competent and tried sanitary director be installed from the beginning. The head of the department should be a man who is thoroughly competent as regards both scientific attainment and executive ability; he should also be endowed with absolute authority and responsibility for everything that may bear on the health of the working force and for the sanitary conditions generally. We are not without men who fill the requirements. Major Gorgas, who was recommended by the medical profession as a member of the canal commission, is one of them. His work in Havana is good evidence of what he could do in even a wider field. Possibly just as satisfactory an arrangement as to have a single medical man on the commission may be secured if its members are fully aware of the needs and appoint a competent director of sanitation, in whom they have sufficient confidence to give him full authority and responsibility in sanitary matters. We trust this will be the case. If some such effective arrangement is not made, every member of the commission will be responsible for the lives that are lost. That the mortality and sickness can be reduced to a minimum is sufficiently evident with our present knowledge of tropical diseases, and that, on the other hand, it can reach a maximum that will be paralleled only by former experience in the same region is equally evident. The responsibility of the commission regarding this matter is a great one, and we trust that it will fully realize it.

THE ETHICS OF EATING.

The influence of the mind over the body is perhaps nowhere better illustrated than in the relation between psychic conditions and digestion. We recently emphasized the value of the deliberate and thorough mastication of food, and took occasion to say that how one eats is often of more importance than what one eats. In the treatment of dyspepsia, it is important to secure freedom from anxiety, pleasant surroundings and such other accompaniments as conduce to enjoyment in eating. Pawlow's classical experiments on gastric secretion in dogs led him to some important conclusions on this subject. One of them is that food eaten without relish and without appetite, although in itself most nutritious and supposedly easy of digestion, may remain for hours in the stomach undigested. The same result often follows when food is eaten while the mind is diverted to other things, especially in case of anger, anxiety, preoccupation, etc. Pawlow says that the old and imperative requirement that food should be eaten with interest and enjoyment is the most emphasized and strengthened of all of his conclusions. Thus food which is nutritious and of the best quality may remain undigested because it lacks presentation in an attractive form or is served amid unpleasant surroundings. Pawlow even says a good word for the preliminary cocktail or the use of some alcoholic in small amounts, as these, by producing slight exhilaration, divert the mind from unpleasant surroundings, and may enable one to forget cares and worries. It is hardly necessary to suggest, however, that this remedy may be more harmful than otherwise. But the enjoyment of eating is the important factor, and of many harmless means to secure this end, it matters little which means is used provided the end be secured. It is well to call attention again to this well-known fact; here is the solution of many an indigestion problem, especially among business men in cities. The psychologic factor in this important function is not to be forgotten.

DESTRUCTION OF WEAKLINGS AN IMPOSSIBLE PROPOSITION.

A little while ago a distinguished educator was reported to have publicly favored destroying the weaklings in society. It was a rather remarkable and not altogether pleasant sequence, if we may judge by the published interviews, that a number of persons were found who supported the alleged views. It is of interest in this connection to note that a London physician is said to have advocated the cessation of all attempts to prevent suicide, particularly on the part of the insane, because this would make for public economy and for the general improvement of the race. The survival of the unfittest is a perennial problem of our civilization, but to our credit be it said that there are few who would be willing to have the problem evaded in the way above suggested. The higher moral considerations, we believe, will always prevail; the care of the helpless and the defective in any community may be taken as the index of

---

1. Beevor: Indian Medical Gazette, October, 1903.

its grade of civilization. Parental and familial love are concentrated on the weak child, and even in the lower animals mother love is often intensified toward the crippled or weak offspring. The attribute of compassion makes this barbarous proposition impossible to consider seriously, but our compassion is superficial if it does not impel us to prevent, as far as possible, the increase of the number of the helpless. There are many evil tendencies to be combated. Even the castration of habitual criminals and the exclusion from the right to marry of those who are mentally, morally and physically unfit, are measures a hundredfold more acceptable than such a return to barbarism as killing off the unfortunate. It would undoubtedly have some effect on the production of this class of degenerates if justice were a little more certain, and if the worst forms of moral degeneracy were discouraged by the strong arm of the law more than is now the case. It is a curious inconsistency of the public that it is so tender to criminals as regards capital and even lesser punishment, while it will listen to and coolly discuss such propositions as that of deliberately killing off the physically and mentally weak and unfortunate.

THE RELATION OF ACID-FAST BACILLI TO THE TRUE TUBERCLE BACILLUS.

Since the discovery of the timothy bacillus by Moeller in 1897, a good deal of attention has been directed to the group of so-called "acid-fast" bacilli, especially as regards their relation to the tubercle bacillus. The occurrence of certain acid-fast bacilli in milk and milk products, and the occasional presence in the sputum, in pulmonary gangrene, of other varieties, will be recalled as circumstances which at first led to mistaken bacteriologic diagnoses. In recent years the bacteria of this group have been well studied, both from the bacteriologic and the histologic standpoint, and differences between them and the true tubercle bacillus have been brought out; differences which, from the histologic standpoint, are rather slight. Moeller, who has consistently studied the acid-fast bacilli in their relation to the tubercle bacillus, and who can rightfully lay claim to an authoritative knowledge of the subject, has presented in a recent article[1] some very interesting facts concerning active immunization against tuberculosis by means of inoculation with bacilli of the acid-fast group. His work is based on the assumption that the acid-fast bacilli are closely allied to the true tubercle bacillus. Reasoning from analogy with vaccinia and smallpox, he advances the idea that it may be possible to produce immunity against tubercle bacilli by inoculation with some of the relatively harmless varieties of acid-fast bacilli. As far as animals are concerned, he has, in fact, shown this to be the case. He shows that the members of the acid-fast group vary greatly in pathogenicity for animals, the least pathogenic being the timothy bacillus and his grass bacillus II, and the most pathogenic his "pseudoperlsucht" bacillus. Between these two lie the milk bacillus and the smegma bacillus, the bacillus of blind-worm tuberculosis, and the drug bacillus, in order of pathogenicity. By means of inoculations with his "pseudoperlsucht" bacillus, he was able to produce a high degree of immunity against tubercle bacilli, both in rabbits and in guinea-pigs. He further showed that tuberculin made from the timothy bacillus and the bacillus of blind-worm tuberculosis caused a reaction in both tuberculous men and cattle, which differed only in degree from the true tuberculin reaction. Taken in conjunction with the work of Koch, who showed that tubercle bacilli could not be distinguished from acid-fast bacilli by agglutination tests, these facts seem of great importance, and suggest that a new field of investigation, looking toward the prevention, if not the cure, of tuberculosis, lies open. Moeller goes so far as to suggest that in his bacillus of blind-worm tuberculosis we may have an agent which is harmless to man, as it does not tend to produce progressive lesions, and which may lead on inoculation to immunity to tuberculosis.

INORGANIC ANALOGIES WITH THE REACTIONS OF IMMUNIZING BODIES AND ALLIED SUBSTANCES.

Strong efforts are being made to bring the work on immunity more and more into the domain of pure chemistry. We have referred in previous issues to Kyes' discovery that lecithin, a tolerably well-known chemical body, may act as a complement. Some recent work by Landsteiner and Jagić[1] indicates that colloidal silicic acid, an inorganic substance, may, under certain circumstances, play the part of an amboceptor or intermediary body. These authors find that colloidal silicic acid in extremely feeble concentration will agglutinate the red blood corpuscles of the rabbit very much as do the organic agglutinins. Thus a 2.5 per cent. suspension of rabbit's corpuscles is agglutinated by a solution of colloidal silicic acid containing only 0.0005 to 0.0001 parts per 1,000. The colloidal solution, like the organic agglutinins, is rendered inactive by the application of heat. The corpuscles agglutinated by silicic acid are not hemolyzed, but if lecithin be added in very dilute solution hemolysis occurs. If too much silicic acid be used the hemolysis is diminished or may not occur at all, analogous to the complement-deviation (Ablenkung) of Neisser and Wechsberg. Fresh blood serum also affords the necessary complement for the hemolysis of silicized corpuscles. The evidence is, therefore, strongly in favor of an amboceptor-like action of the colloidal silicic acid. Someone should now undertake to determine whether or not colloidal silicic acid will unite directly with lecithin to form a body comparable with the crystallizable "lecithid" obtained by Kyes by the union of the amboceptor of snake-poison with lecithin, and a further attempt might be made to effect a union between one of the complements occurring naturally in the blood serum and the colloidal silicic acid, and to separate this compound as a pure substance. Once the chemistry of immunity has been brought into the realm of substances which can be satisfactorily analyzed, the possibility of constitutional formulæ becomes alluring. Should this be realized, we shall have made a long step toward the direct synthesis of the immunizing substances, a Mecca of the pharmacology and therapy of the future.

Medical News.

CALIFORNIA.

More Plague.—During February 6 cases of plague were reported in San Francisco, with 4 deaths. Provisional diagnosis was made in 5 of the cases.

Fire in County Hospital.—A fire which broke out in the San Bernardino County Hospital, February 20, did damage amounting to $6,000, and endangered the lives of a number of patients, all of whom were removed without casualty.

New Hospitals.—The Sisterhood of Mercy will soon establish a hospital at Barber, and one at Stirling City. It is understood that the president of the Diamond Match Company has donated $1,000 and a site for each of these hospitals.

January Deaths.—The deaths for the month in the state, exclusive of San Francisco, were 868, equivalent to an annual death rate of 15.96 per 1,000. Tuberculosis caused 165 deaths; pneumonia, 125, an increase of 25 per cent. over the preceding month; heart disease, 83; stomach disease, 55, and cancer, 39.

Personal.—Dr. Charles F. Craig, U. S. Army, delivered the Lane lecture at Cooper Medical College, San Francisco, February 19, on "Water as a Carrier of Disease."——Dr. Ray L. Wilbur, Stanford University, who is now studying in Germany, has resigned from the faculty of the university and will enter private practice.——Dr. Auren A. Stafford has been elected president of the Alameda Board of Health.——Dr. Robert V. Day has been appointed city chemist of Los Angeles.——Dr. Samuel E. Latta has been elected president, and Dr. Sylvester B. Davis secretary and health officer of the Stockton Board of Health.

DISTRICT OF COLUMBIA.

New Naval Hospital.—The contract for building the new naval hospital at Washington has been awarded. The bid for constructing the six buildings, including the administration building, was $141,900.

Personal.—Dr. Robert Perkins, senior resident physician at Emergency Hospital, has resigned to become resident physician at the New York Lying-in Hospital. He has been succeeded by Dr. Thomas F. Lowe. Dr. Perkins was presented with a handsome pocket surgical case by the physicians and nurses of the hospital on January 30.

Fined and License Revoked.—Dr. James C. Dowling was recently fined $10 for neglecting to report a case of diphtheria to the health department.——The medical supervisors of the district have revoked the license of Dr. Sigmund A. Czarra, to practice medicine in the district on account of unprofessional conduct in the alleged distribution of objectionable literature.

New Qualifications for Practice.—Senator Clay has introduced a bill providing that all physicians who have practiced medicine in any state of the United States for ten years or more, and who can furnish certificate of good character from the states in which they have practiced, shall be allowed to practice in the District of Columbia without examination on payment of the fee.

To Limit Communicable Disease.—A bill has been introduced in the senate to provide for the further prevention of the spread of communicable diseases, by requiring the physician in charge to notify the district health officer of each case of measles, whooping cough, chicken-pox and cerebrospinal meningitis, in addition to the diseases already listed, and furthermore to send a second notice when each patient has fully recovered. A fine of $100 or imprisonment for 30 days is the penalty provided for violation.

ILLINOIS.

Personal.—Dr. Joseph P. Comegys, Rock Island, has been appointed local surgeon for the Burlington system, vice Dr. Calvin Truesdale, deceased.

Scarlet Fever in Murphysboro.—It is reported that there have been more than one hundred cases of scarlet fever in Murphysboro in the last four weeks, and that thus far ten deaths have occurred.

Menaced by Diphtheria.—Lake City, a town near Mattoon, is suffering from an epidemic of diphtheria. All infected houses are quarantined, public schools have been closed, and public gatherings prohibited.

Examination Postponed.—The examination of candidate medical officers for the National Guard has been postponed until April 30. All desiring to take this examination should make application to the Surgeon General through military channels. The examination will he held at Rush Medical College, Chicago, beginning at 9 a. m.

Chicago.

Thousands for Hospital.—By the will of the late Thomas D. Lowther a sum of not less than $20,000 from the residue of the estate is devised to the Augustana Hospital.

Predicts Increase in Disease.—The report of the director of the Municipal Laboratory justifies the Department of Health in foreboding an increase in influenza, pneumonia and the impure-water diseases during the next few weeks.

Deaths for the Week.—In the week ended February 27, 674 died. Of these 151 died from pneumonia; 60 from consumption; 60 from heart disease; 46 from violence; 37 each from Bright's disease and bronchitis, and 32 from cancer.

Smallpox.—Two migrant cases of smallpox were sent to the Isolation Hospital last week. Both came from Pennsylvania; one had never been vaccinated and the other was vaccinated 40 years ago. There are now three cases at the hospital; at this time last year there were 59.

To Stop Spitting.—It is rumored an order has been passed by the City Council ordering the police to arrest all expectorators on sight. More than three years ago an ordinance was passed prohibiting spitting on the floors of public conveyances or public buildings. It is still in force, but not enforced.

Continued Cold Kills.—For the four weeks in February the death rate has progressively increased as follows: Week ended February 6, 15.92 per 1,000; February 13, 17.68 per 1,000; February 20, 17.41 per 1,000, and February 27, 18.02 per 1,000. This high mortality is due to the protracted cold weather; it is not so high, however, as the rate during the corresponding weeks of 1903.

Must Dilute Carbolic Acid.—The number of suicides from carbolic acid, and the ease with which this poison can be obtained without the prescription of a physician, has led to the drafting of an ordinance by the Retail Druggists' Association which contains the following provisions:

> Every druggist or other person who shall sell or give away any carbolic acid or any solution thereof containing more than 5 per cent. of carbolic acid, without the written prescription of a physician, except as hereinafter provided, shall be fined not more than $25 for each neglect.
>
> It shall be lawful to sell without the prescription of a physician a mixture containing equal proportions of carbolic acid, glycerin and alcohol.

INDIANA.

Smallpox.—During January 569 cases were reported from 37 counties, with 8 deaths. In January, 1903, there were 921 cases in 56 counties, with 50 deaths.

Physician's House Burned.—The house of Dr. Joseph Gardner, four miles south of Bedford, was burned to the ground, February 20. The loss exceeded $15,000, with only a small insurance.

Measles Epidemic.—It is reported in the local press that Hamilton County has 1,000 cases of measles, of which fully one-half are in Noblesville. Only one death has occurred. Several schools have been closed on account of the disease.

The Kluge Case.—Dr. William Kluge, Indianapolis jail physician, who was on trial for practicing medicine without a license, was found guilty by the jury and fined $50. He says he will appeal to the higher courts. Meanwhile the county commissioners have removed Dr. Kluge from his position and have appointed Dr. Harvey Hadley in his stead.

January Deaths and Disease.—There were reported 3,177 deaths in Indiana in January, an annual rate of 14.8 per 1,000. In the corresponding month last year there were 2,910 deaths, a rate of 13.2 per 1,000. Tuberculosis caused 408 deaths; typhoid fever, 38; diphtheria, 45; scarlet fever, 25; measles, 38; whooping cough, 7; pneumonia, 540; diarrheal diseases, 23; cerebrospinal meningitis, 41; influenza, 50; puerperal fever, 15; cancer, 103; violence, 132, and smallpox 8. The city death rate was 18.8 per 1,000, and that of the country 12.8 per 1,000. The cities showed a higher rate than the country in tuberculosis, typhoid, diphtheria, scarlet fever, pneumonia, diarrheal diseases, cerebrospinal meningitis, puerperal fever and violence, while the country rates were higher for measles, whooping cough, influenza and cancer. Tonsillitis was the most prevalent disease and measles the next most prevalent. Pneumonia stands fourth in the list of diseases, and caused 540 deaths. Cerebrospinal meningitis was the least prevalent. The reports show more typhoid fever than is usual in January. A complete summary shows that the public health in January, 1904, was not so good as in January, 1903.

IOWA.

Hospital Fair a Success.—The fair at Carroll for the benefit of Mercy Hospital netted more than $5,000 for the building fund.

Economic Move.—To reduce expenses the Sioux City College of Medicine, on May 1, will move from the Y. M. C. A. building back to its old quarters at Fourteenth and Jones streets.

Personal.—Dr. Fred W. Powers, Waterloo, has been elected president of the State Board of Medical Examiners, in place of Dr. Charles B. Adams, Sac City, term expired.——Dr. H. C. Hull, Crawfordsville, was badly hurt, February 10, by his horse slipping on the ice and falling on him.

Appropriation for State Institutions.—The house of representatives has passed the following appropriations for buildings: Iowa Hospital for Insane, Mount Pleasant, $87,100; Iowa State Hospital, Independence, $109,800, and Iowa Institution for Feeble-Minded Children, Glenwood, $150,400.

Pre-nuptial Instruction Denied.—The Dashiell bill was killed, February 25, by unanimous vote on the ground that its provisions were contrary to the constitutional guaranty of liberty and the pursuit of happiness. The bill proposed to require each prospective bride and groom to appear before some physician for instruction, with a view to reduce the number of defective children.

MARYLAND.

The Title of "R. N."—A bill for the registration of trained nurses with the title of "R. N.," was introduced in the legislature February 26.

County Coroners Named.—The governor has nominated Dr. Ricketts Nelson as coroner for Cecil County, and Dr. Dennis B. O'Neal for Allegany County.

Should Physicians Issue Burial Permits?—A bill has been introduced in the legislature to authorize physicians in Baltimore County to issue burial permits. Dr. John S. Fulton, secretary of the State Board of Health, says: "There are serious objections to the same person issuing certificates of death and burial permits, and it is easy to see how serious evils would result therefrom."

Baltimore.

Library Building for Medical and Chirurgical Faculty.—The bill appropriating $100,000 for the erection of a library building for the Medical and Chirurgical Faculty of Maryland in Baltimore was introduced in the legislature, February 25, and was at once referred to the Ways and Means Committee.

Increased Illness.—There is much sickness and a high death rate is noted. An examination of the reports of the City Health Department shows that the excess is due to influenza, pneumonia, bronchitis, chicken-pox, scarlet fever and whooping cough. In the week ended February 20 there were 47 deaths from pneumonia alone, and for the week ended February 27 50 deaths.

Smallpox in Lodging House.—Two cases of smallpox, both unvaccinated, were discovered at an overcrowded home for poor lodgers on February 23. The house has 400 beds and 700 inmates. The two were sent to quarantine and a large force from the health department, in spite of resistance, vaccinated all the inmates who could be caught. The place was fumigated and two other suspects were sent to the House of Detention.

Governor Nominates Coroners.—Governor Warfield has nominated to the legislature the following as coroners for Baltimore: Dr. G. Milton Linthicum, northern district; Dr. C. Frank Jones, southwestern district; Dr. Benjamin S. Hayden, central district; Dr. Otto M. Reinhardt, southern district; Dr. Silas Baldwin, northwestern district; Dr. Frederick Caruthers, northeastern district; Dr. Patrick F. Martin, western district; Dr. Thomas H. Sudler, eastern district, and Dr. James D. Iglehart, at large. The city coroners are named by the city senators. Drs. Jones, Baldwin, Martin and Reinhardt represent reappointments; the rest are new men.

Hospitals Overcrowded.—The University and City hospitals are overcrowded. At the former cots have been placed in the public wards, and private accommodations have received a double number of patients; still many have had to be turned away, and it is proposed to utilize the nurses' sitting-room for a ward. It is said that many of the patients under ordinary circumstances would have been treated at their homes, but the fire has made it necessary for them to seek a hospital. Cots have also been utilized at the City Hospital. The hospital authorities feel so grateful for the saving of their institution and the ready help offered in removing their inmates when the fire threatened that they are willing to submit to any crowding or inconvenience in order to serve the community.

MASSACHUSETTS.

Hospital Bequests.—By the will of George B. Upton, Milton, the Massachusetts General Hospital receives $10,000 and the Massachusetts Charitable Eye and Ear Infirmary, $5,000.

Personal.—Dr. George W. Ryan, senior interne at the Calvin Emergency Hospital, Brockton, was operated on for appendicitis, February 23.——Dr. Thomas B. Shaw, Worcester, has returned from a trip to England.

Medical Inspectors Elected.—The Cambridge Board of Health has re-elected Drs. W. H. Clancy, William E. Fleet, Nelligan, Thomas J. Leahy, Eugene A. McCarthy and Francis J. Barnes, medical inspectors of schools, and has elected Drs. Charles M. Hutchinson, Myron L. King and L. Arthur Moll, to fill vacancies on the staff.

District Nurses in Boston.—The annual meeting of the Instructive District Nursing Association showed that a successful work had been done, but disclosed an excess of expenses over receipts during the past year of more than $1,300. Eleven nurses were employed on the districts of the Boston Dispensary District physicians, one works in Cambridge, and three are obstetric nurses.

Institutions Need Money.—The Boston Board of Trustees for Pauper Institutions has applied to the mayor and aldermen for a grant of $210,000 to be expended in building an addition to the hospital and an addition to the power plant. This board was severely criticised last fall by a majority report and completely exonerated by a minority, as a result of a prolonged investigation. In view of this action there will probably be difficulty in securing this grant, which is so much needed.

NEW YORK.

Health of Albany.—The January mortality of Albany was at the annual rate of 14.50 per 1,000. Only 4 cases of typhoid fever were reported, with one death.

Smallpox in Owego.—The president of the Owego Board of Health announces that there are several cases of smallpox in the city, and his report is confirmed by the secretary of the State Board of Health.

Hospital Open.—St. Peter's Hospital, Albany, has opened its new addition, which has been erected at a cost of about $60,000. The building is four stories high and contains five wards, a large operating room, solaria, and a roof garden.

Only Two Passed Examination.—Of the five candidates for the position of superintendent of the new State Hospital for Consumptives, Raybrook, Drs. John H. Prior, Buffalo, and Frederick L. Hills, Binghamton, alone passed the examination. The other three failed on the practical diagnosis of tuberculosis by examination of patients.

Personal.—Dr. Dennis Lucey, formerly physician to the Elmira Reformatory, who is ill with tuberculosis, has been removed to a private sanatorium.——Dr. James N. Vander Veer, Albany, was recently operated on for appendicitis.——Dr. Henry E. Clarke has succeeded Dr. Lemon Thomson as health officer of Glens Falls.

New York City.

Dr. Delafield Ill.—Dr. Francis Delafield is reported to be ill with pneumonia, but it is said that his condition is steadily improving.

Charity Ball.—The Nursery and Child's Hospital will receive about $8,000 as the proceeds of the twenty-fourth annual charity ball recently held at the Waldorf-Astoria.

Conrad Again Indicted.—Dr. Edward E. Conrad was rearrested, February 19, on the same charge which was dismissed by the grand jury two days before. Bail was fixed at $10,000.

Personal.—It is announced that Dr. Frederick Peterson has resigned as a member of the State Commission in Lunacy. Dr. Peterson is the president of the board.——Dr. Emil Mayer has been appointed adjunct attending laryngologist to Mount Sinai Hospital.

County Medical Society Hears Mayo.—Dr. William J. Mayo, Rochester, Minn., read by invitation an article on "Indications for, and Result of, Operations on the Common Duct of the Liver" before a large and enthusiastic meeting of the New York County Medical Society, February 29.

Will Examine Gas.—The coroners from New York and Kings County report that in the last thirteen months deaths from asphyxiation in New York City were 76, and in Kings County 72. An analysis of gas made by the city chemist shows that it contains 24.34 per cent. of carbonic acid. According to Charles E. Doremus of the College of the City of New York, 12 grains is sufficient to kill the average man. Accordingly Senator Martin has introduced a bill calling for an investigation of the gas situation in New York City.

Buffalo.

Personal.—The board of aldermen has increased the salary of Fire Surgeon O'Brien from $1,500 to $2,000.——Dr. William R. Pryor of New York City was recently given a dinner by D. Matthew D. Mann.

High Winds and Intestinal Diseases.—Health Commissioner Greene has sent out circulars of inquiry among the physicians asking for information concerning the effect of high winds on the lake on intestinal diseases. It is his theory that because of the winds the water in the Niagara river, the source of Buffalo's water supply, becomes filled with sand, which produces irritant effects on the mucosa of the stomach and intestines.

Anti-Vaccinationist Active.—Officials of the health department assert that H. E. Sturdevant, who recently lost a law suit against the city, in which he claimed $25,000 damages for the death of his six-year-old daughter, on the ground that she died as a result of compulsory vaccination, is circulating a petition about the country in which he asks financial assistance to enable him to prosecute his suit. Lucille Sturdevant died after having been vaccinated while she was a pupil at one of the public schools. A stone erected over her grave in Forest Lawn Cemetery states that she died of compulsory vaccination. The petition circulated by Sturdevant purports to have the endorsement of the Anti-Compulsory Vaccination League of New York City.

Typhoid in Buffalo and Elsewhere.—The census report of the United States on typhoid fever shows that Buffalo is quite as free from typhoid fever as are other cities of its class. The death rate in Pittsburg from the disease in 1901 was 124.7 per 100,000, Allegheny 100.8 per 100,000. The other cities of the union which have a greater proportion of deaths per 100,000 than has Buffalo are as follows: New Haven, Conn., 92; Charlestown, S. C., 73.8; Washington, 67.3; Atlanta, 61.7; Minneapolis, 57.6; Troy, N. Y., 57.3; Louisville, 56.3; Cincinnati, 53.5; Denver, 47.9; New Orleans, 47; Nashville, 45.5; Kansas City, 42.9; Reading, Pa., 42.7; Wilmington, Del., 42; Cleveland, 35.9; Columbus, 35.5; Richmond, 34.8; Grand Rapids, 34.7; Salt Lake City, 34.5; Philadelphia, 33.3; St. Louis, 33.3; Hartford, 36; Scranton, 30.1; Toledo, 0.30; Los Angeles, 29.1; New Bedford, 28.8; Indianapolis 27.4; Baltimore, 27.3; Paterson, N. J., 27; Buffalo, 26.8. The two cities larger than Buffalo having a lower death rate of typhoid fever are New York, with a death rate of 20.3 per 100,000, and Boston, with 24 per 100,000, and in Buffalo's class San Francisco, with a death rate of 20 and Detroit with but 15.7 per 100,000. During 1902 and 1903 Buffalo's death rate from typhoid was increased because of an epidemic at West Seneca. The disease spread among workmen constructing the steel plant so that many of them living in Buffalo contracted the disease or were brought to the hospitals of the city for treatment. For 1902 the death rate from typhoid, accordingly, was increased to 35 per 100,000, and during 1903 was 33 per 100,000. At present the city is free from the disease.

PENNSYLVANIA.

Physician Stricken.—Dr. David L. Bailey, Carbondale, recently had a cerebral hemorrhage. He is now making satisfactory progress toward recovery.

Bequest to Philadelphia Hospital.—By the will of Mrs. Elizabeth Solliday, Doylestown, $1,000 is bequeathed to the Presbyterian Hospital and Dispensary, Philadelphia.

Physicians Majority of School Board.—The school board of Wilkesbarre consists of six members, two of whom, Drs. Charles Long and Boyd Dodson, are newly elected, and two other physicians are hold-over members.

Will Not Shave Consumptives.—By the new rules of the Altoona Board of Health barbers are no longer permitted to shave consumptives in the communicable stage of the disease. It is not stated whether or not rules for differential diagnosis are made part of the new regulations.

Report of Butler Epidemic.—The State Board of Health has ordered printed 5,000 copies of the report of Dr. Wilmer R. Batt, state quarantine officer, on the typhoid epidemic in Butler. These are to be distributed throughout the state for information and guidance of health and other authorities in dealing with this disease.

Pennsylvania Leads in Smallpox.—Pennsylvania has the unenviable distinction of having within its borders more smallpox cases than any other state. From December 20 to January 23 there were in Philadelphia alone 387 cases, with 120 deaths, and in Allegheny County 112 cases and 26 deaths. Lack of authority to cope with the disease is stated to be the cause of its prevalence.

Election.—At the annual meeting of the Butler County Medical Society held in Butler, January 13, the following officers were elected: President, Dr. W. Rush Hockenberry, Slippery Rock; vice-president, Dr. Willard B. Campbell, Harrisville; secretary, Dr. William B. Clark, Butler; treasurer, Dr. M. Edward Headland, Butler, and censor, Dr. Harvey D. Hockenberry, West Sunbury.

Philadelphia.

Would Not List Consumption.—Compulsory registration of tuberculosis as a contagious disease was voted down by the Philadelphia County Medical Society by a tie vote.

Resignations.—Drs. John H. Musser and J. Chalmers Da Costa, medical civil service examiners, have resigned.——Dr. H. F. Dietrich, resident physician at the Samaritan Hospital, has resigned.

Hospital in Quarantine.—St. Luke's Hospital was placed under strict quarantine by the chief medical inspector of the Bureau of Health, February 23, as two cases of smallpox had developed among the nurses at the institution. The two nurses were removed to the Municipal Hospital.

Alumni Dine.—On February 20 the alumni of the medical department of the University of Pennsylvania held their annual banquet. Dr. George E. de Schweinitz acted as toastmaster, and Surgeon-General Robert M. O'Reilly, U. S. Army, and Drs. George W. Guthrie, Wilkesbarre, and Horatio C. Wood, Aloysius O. J. Kelly and Roland G. Curtin of Philadelphia responded to toasts.

Crile in Philadelphia.—Dr. George W. Crile, Cleveland, delivered an address at Jefferson Medical College, February 23, on "Some Observations on the Surgical Physiology of the Vascular System." In the evening he was the guest of honor at the tenth annual banquet of the W. W. Keen Surgical Society, at which about 60 were present, Dr. Hobart Amory Hare officiating as toastmaster.

Med.-Chi. New Hospital Open.—The new buildings of the Medico-Chirurgical Hospital, replacing those destroyed by an explosion a year ago, were thrown open February 23. The formal ceremonies consisted of the presentation of the buildings to the board of directors by ex-Mayor Charles F. Warwick, the acceptance on behalf of the board by Hon. Abraham M. Beitler, and an address by Attorney-General Hampton L. Carson, on "Advance in Medicine."

Health Report.—Typhoid fever is on the increase, and the health bureau announces for the week ended February 27 148 new cases, the greatest number recorded in any week during the year. The disease seems to be prevalent throughout the city and is not confined to any one portion. As a result of the prevalence of typhoid the city's death-rate is also greatly increased, 23 deaths being reported from this cause alone. This is an increase of 11 over the preceding week. There is a notable decrease in the number of smallpox, diphtheria and scarlet fever cases reported for the past week. The total number of deaths reported for the week was 693. This is an increase of 88 over the previous week, and 54 over the same period last year.

Grateful to Carnegie.—The fellows of the College of Physicians of Philadelphia, as a token of their appreciation of the largest gift ($50,000) to the college in the 116 years of its existence, have authorized the president, Dr. Horatio C. Wood, and the vice-president, Dr. Arthur V. Meigs, to express the thanks of its members to Andrew Carnegie, the benefactor; also to inform the donor that, by a resolution of the college, a suitable tablet is to be placed in the college building to commemorate the generosity that has enabled them to provide for the growth of their great medical library. By the generosity of S. Weir Mitchell these sentiments have been inscribed in water colors on a beautiful artistic diploma to be presented to Mr. Carnegie.

Lectures for Medical Inspectors.—Director Martin of the Department of Health has arranged a course of lectures on contagious diseases for the benefit of the medical inspectors and of physicians at large. The course was inaugurated February 16, by lectures on the diagnosis of smallpox, by Drs. William H. Welch and Jay F. Schamberg. The succeeding lectures are as follows:

February 26.—Normal course of vaccinia, spurious results, vaccinal eruption, complications, technic and vaccination scars.

March 4.—Symptomatology and diagnosis of scarlatina, rubella, measles and chicken-pox.

March 11.—Skin diseases; what are apt to be confounded with the exanthematous fevers?
March 18.—Skin diseases apt to be encountered among school children.
March 25.—Leprosy and syphilis.

How to Detect Diseases of Children.—A series of lectures is now being given for the benefit of school principals and teachers. The general subject is the diseases of children and the methods of detecting them. The course commenced on February 23 and continues until March 30. The schedule is as follows:

February 23.—Introduction, with remarks on the nervous diseases of children, Dr. S. Weir Mitchell.
February 24.—"The Early Recognition of Disease," Dr. Hobart A. Hare.
March 2.—"The Eyes of School Children," Dr. George E. de Schweinitz (lantern illustrations).
March 9.—"School Life in Its Relation to the Deformities of Childhood," Dr. H. Augustus Wilson (lantern illustrations).
March 16.—"*The Efficacy of Vaccination; the Early Symptoms* of Smallpox, Scarlet Fever and Measles," Dr. Jay F. Schamberg (lantern illustrations).
Marc[illegible] "C[illegible] Skin Diseases of School Children," Dr. Jay F. [illegible] illustrations.
Marc[illegible] [illegible]litions of Ch[illegible]hood and Youth a Menace to Health." Dr. D. D. Smith.

GENERAL.

Appeal for Journal.—Dr. William Osler, president of the Association of Medical Librarians, has issued a circular appeal urging the support of the *Medical Library and Historical Journal*, the second volume of which was entered on with 1904.

Ratification in New York.—As an indication of the hearty endorsement the reorganization plan is receiving in New York State it may be mentioned that the societies of the counties of Albany, Cayuga, Chemung, Dutchess, Franklin, Kings, Monroe, Oneida, Onondaga, Ontario, Rensselaer, Schenectady, Broome and New York have ratified the plan for union of the two state bodies.

Panama and Its Sanitation.—Dr. J. C. Perry of the U. S. Public Health and Marine-Hospital Service, whose elaborate report on the Panama Canal route, its sanitary condition, needs and possibilities, has been given to President Roosevelt, describes the two extremities of the route as exceedingly unsanitary and unhealthy, but he points out that extensive filling in of swamp land, proper disposal of sewage, protection from mosquitoes, destruction of unsanitary native houses, and the installation of a supply of good water will create a different character and make the places healthy.

FOREIGN.

Organization of the Profession in Germany.—The successful outcome of the united stand taken by the physicians at Cologne, mentioned editorially in our last issue, has been followed by a similar decided victory at Krimmitschau.

Opposition to Tuberculosis Sanatorium.—The Paris authorities were on the point of commencing the construction of a model tuberculosis sanatorium at Montmorency, an ideal site, on ground offered by the Duke de Dino, when the surrounding property owners officially protested and the project has been abandoned for the present.

The Chair of Surgery at Vienna Filled.—Prof. Julius Hochenegg of Vienna has been installed in the II chair of surgery at Vienna, vacant since Gussenbauer's death. Several German professors had refused the place, and after Garré had accepted it the negotiations were broken off at the last minute. Hochenegg is 43 years old, a pupil of Albert's.

Yellow Fever Expeditions to South America.—Drs. E. Marchoux and P. L. Simond of the Paris Pasteur Institute, arrived in Rio Janeiro, February 17, to study yellow fever. A fund has also been raised by the merchants and wharf owners of Hamburg to send Drs. Otto and Neumann of the Institute for Tropical Diseases to South America to study these diseases on the spot.

Some Anniversaries Among Our German Confreres.—Professor Edwin Klebs, the eminent pathologist, well known to Americans, celebrated his seventieth birthday February 6. The *Corr.-Blatt f. Schweizer Aerzte* does homage to him as its founder and first editor thirty-four years ago.——Professor Ernst Haeckel of Jena spent February in Italy to escape the celebration of his seventieth birthday, on the 16th, with which his friends were preparing to honor the world-wide fame of the great biologist.——The Vienna Medical Faculty is soon to renew the medical diploma conferred fifty years ago on Professors Weinlechner, von Valenta and Haas.

Alleged Origin of Syphilis.—At the last meeting of the German Society for the Prevention of Venereal Disease, held at Berlin, February 5, Professor Iwan Bloch delivered an address on the "Origin of Syphilis," to which he has devoted years of study. He stated that nothing has been discovered in history or prehistoric remains to indicate that syphilis was known in Europe until after it was brought from America by the Columbus expeditions. He asserts that it then ravaged Europe with the malignancy of a newly imported disease, while it had long existed on the western continent. From this view of syphilis as the "specific disease of modern times" he drew conclusions favorable to the prospects of its final extermination in time, in which Virchow, among others, firmly believed.

Expositions of Home and Municipal Hygiene.—The Germans have been holding some interesting exhibitions of articles and appliances connected with the hygiene of the home, the school, the workshop and the city. It has been found that these exhibitions are very instructive for the general public, and attract much attention and interest. Berlin has a permanent exhibition of everything tending to promote the welfare of the workingman at home and at work, and Dresden recently held a very popular "Cities' Exhibition," showing in detail and on a most extensive scale all that tends to promote the health of a community. The First International Congress for School Hygiene, to convene at Nuremberg, April 4, is to make a prominent feature of the exhibition connected therewith.

Campaign Against Charlatans in Germany.—At Bayreuth a charlatan has been sentenced to fourteen days' imprisonment on account of the death of two children from diphtheria under his hands. At Lubeck another charlatan, a woman, has been sentenced to one week's imprisonment and $7.50 fine. At Berlin another has been sentenced to a fine of $125 and another to eighteen months' imprisonment. At Mainz a charlatan, on account of three deaths under his procedures, was sentenced to a year's imprisonment and $125 fine, and at Torgau a barber was sentenced to a month's imprisonment for quack practices. At Trier the editor of a daily paper was fined $7.50 for inserting an ad guaranteeing the cure of deafness. He appealed the case, asserting that he supposed deafness was curable, and he was acquitted.

Poisoning from Food.—A bean salad made from canned beans caused severe poisoning among the pupils of a Darmstadt cooking school. There have already been eleven deaths. Professor Gaffky of Giessen has examined the beans and ascribes the poisoning to some bacterial toxin. He thinks that there must have been spores on the beans which survived the cooking in the can and developed in time, generating the toxin in question. Another serious and extensive intoxication was also reported elsewhere from the use of potato salad made from potatoes which had been cooked and sliced the day before.——An epidemic of lead poisoning is reported from Budapest, affecting more than 100 persons with a number of deaths. It has been traced to the kettles in certain distilleries which were lined with lead recently to shorten the process of making alcoholic drinks.

The Paris Information Bureau for Scientists.—Physicians and other scientists visiting Paris are charmed with the workings of the new Information Bureau established in luxurious quarters at the Sorbonne. They find there employes speaking English, French, Russian, German and Spanish, with every information for persons seeking opportunities for study or research, and the subjects are classified so that no time is wasted. The bureau can be reached by telephone. It is in charge of Dr. Blondel, the general secretary of the International Association of the Medical Press, who has already compiled nearly three thousand different catalogues of books, documents, lectures, etc., bearing on given subjects. The bureau has been informally open since last August, but the official inauguration occurred February 20 under the auspices of the "Conjoint Committee for the common interests of the City of Paris and of the University."

Recent Decisions of the German Medical Court of Honor.—A physician was reproved for signing a certificate testifying to the mental disease of a subject without a personal examination, merely accepting the assertions of the other physician who had examined the patient and signed the certificate with him. Another physician was reproved for "selling his practice," and another for placing two signs a yard square on his house, with the words "To the eye and ear clinic," followed by his name in smaller figures. He was ordered to use only a single sign and have nothing but his name on it, with a hand as guide for the direction. Another decision declares that it is contrary to professional ethics for a physician when his fee is paid at once to voluntarily offer to deduct a certain discount. "Such a procedure is altogether unworthy of a physician, as it places his medical services on the same plane as merchantable commodities." In another case the decision was given that a physician is under no obligations when a patient applies to him to inform the physician who has been previously treating the patient. The only exceptions are when the patient still maintains professional relations with the first physician.

Medical Congresses To Be Held in Europe in 1904.—The following is an almost complete list of the medical conventions to be held in Europe this year, except those of Italy. There may also be mentioned the Fourth Pan-Hellenic Medical Congress at Athens in May, and the French Congress of Neurology at Pau in August.

March 3-8.—Twenty-fifth German Congress of Balneology. Aix la Chapelle.

April 4-9.—First International Congress of School Hygiene. Nuremberg.

April 4-9.—French Congress of Climatotherapy and Hygiene. Nice.

April 5-10.—Fourth French Congress of Gynecology. Rouen.

April 5 9.—Third German Congress of Orthopedic Surgery. Berlin.

April 6-9.—Thirty-third German Congress of Surgery. Berlin.

April 18-30.—German Congress for Experimental Psychology. Giessen.

April 18-21.—German Congress of Internal Medicine. Leipsic.

April 25-26.—German Congress of Psychiatry. Göttingen.

May 2.—French Congress of Ophthalmology. Paris.

May 27-28.—Meeting of Inner Council of International Antituberculosis Central Bureau. Copenhagen.

July 20-24.—Tenth Quadrennial Congress of Polish Physicians and Scientists. Lemberg.

July 26-29.—British Medical Association. Oxford.

August 1-4.—Seventh International Congress of Otology. Bordeaux.

August 9-11.—Northern Congress of Surgery. Göteborg.

August 30.—Sixth International Congress of Physiology. Brussels.

September 12-17.—Fifth International Congress of Dermatology. Berlin.

September 16-19.—German Public Health Congress. Dresden.

September 17-24.—Seventy-sixth German Congress of Physicians and Scientists (Naturforscher Congress). Breslau.

September 19-21.—Tenth International Congress of Ophthalmology. Lucerne.

September 24 30.—Third International Antituberculosis Congress. Paris.

Third Week in October.—Seventeenth French Congress of Surgery. Paris.

Third Week in October.—French Congress of Urology.

Police Interference with the Russian National Medical Congress.—This occurrence was mentioned editorially last week. The congress was the Ninth Biennial National Medical Congress, "in memory of N. J. Pirogoff," and had assembled 2,136 physicians from all parts of Russia. There were 27 sections and 368 communications were presented in the course of the 2 general assemblies and the 177 section meetings. These congresses are always liberally subsidized by the national treasury, the departments of the interior and of public instruction, as well as by the local and provincial governments. The city also entertained the members lavishly. One of the principal addresses was by Lewascheff of Kazan, who asserted that the southwestern part of Russia offered peculiar advantages for the climatic treatment of tuberculosis, especially when supplemented by "that incomparable curative drink, kumiss." A health resort for the entire world ought to be organized there by the combination of these factors, but instead, dirt, discomfort, adulteration of kumiss and other disappointments prevail there. He urged the radical reorganization of kumiss therapy as the most imperative task for the profession in Russia. Professor Rasumowski of Kazan presided, and at the closing meeting, after reading the general resolutions of the congress, he stated briefly that the resolutions adopted by the various sections for certain reasons would not be read, and abruptly adjourned the congress *sine die*. Our French exchanges add—what is not mentioned in the Russian journals—that the police at once cleared the hall, and the protests of the section members and others were drowned by the loud strains of a military band. The offensive resolutions referred to the dangers of overcrowding and lack of sanitation, etc., as factors in the spread of disease. As the Jews are forced by the city regulations to live in their confined Ghetto, the demands of the hygienists in the congress conflicted with these ordinances, and the resolutions were consequently suppressed, and with them all the other resolutions of the sections.

DUBLIN LETTER.

The Irish University Question.

My last letter spoke of the history of university education in Ireland, and I shall now sketch some of the schemes which have been put forward as solutions of the problem. Although the plans for the session of parliament do not include any treatment of the question, its settlement can not be much longer postponed, as it is undoubtedly the most pressing matter in the field of Irish politics. The possible solutions of the question are not more than three or four. One is that such alterations might be attempted in the constitution of Trinity College as to render it more acceptable to Roman Catholic feeling, or, again, a teaching college under Roman Catholic management might be established in connection with the Royal University. Or finally, a new college, under Roman Catholic management, might be affiliated with Trinity College, in the existing University of Dublin. The first scheme, though best from a purely educational point of view, is probably not practicable at present, owing to the irreconcilable attitude adopted by the Roman Catholic clergy. The second scheme is more possible, but has the great objection that it will handicap the new college by connecting it with the name "Royal University," an institution admittedly a failure. In addition, the Roman Catholic laity fear lest such a college, being practically free of all Protestant influence, should be so much in the hands of the clergy as to be medieval in character. The third scheme has much in its favor, and is the one most before the public. It is supposed to be the solution suggested by Mr. Wyndham, the chief secretary for Ireland, and has gained the adherence of Mr. Mahaffy, one of the most influential fellows of Trinity College, and of Lord Dunraven, better known in America as a yachtsman, and of many Roman Catholic bishops and of a very strong body of Roman Catholic laity. The new college would have an established status at once, owing to its connection with Dublin University, whose degrees are held in respect throughout the world. The opposition to it will mostly come from the most conservative sections of Irish public opinion, and from those who fear their vested interests in Trinity College, or in its degrees, may be interfered with. Unfortunately, Mr. Wyndham and Lord Dunraven have obscured the nature of their scheme by including in it a place for Queen's College, Belfast, as a constituent college of the Dublin University. This is meant as a sop to the Presbyterian body, who practically control Queen's College. Now Belfast is some hundred and twenty miles from Dublin, and the two cities have little community of interest or sympathy of thought. It is strongly held that a university to be a university in any true sense must have a certain unity, as well of feeling and thought as of locus. If this offensive feature were dropped, there is every reason to suppose that the main outline would be accepted.

X-Rays in the Courts.

A law suit of unusual interest has just been heard in the high courts here. A child who was supposed to have a needle in his knee received repeated *x*-ray examinations to locate the needle. No needle was discovered, but a severe *x*-ray burn, resulting in an ulcer, appeared on the inner side of the knee, and took several months to heal. The examinations were actually made by an unskilled person—a mechanic—acting under the immediate supervision of the medical man, who was himself admittedly ignorant of a practical knowledge of radiography. It appears also that he did not recognize the ulcer as an *x*-ray burn, but after its formation continued to examine the knee for the hypothetical needle. Finally the child passed from under his care, and the parents, having discovered the cause of the injury, sued for damages, alleged to be due to negligence. The trial occupied seven days, and much expert evidence was brought forward on each side. Assuming the truth of the statement of the child's relatives that the *x*-ray tube had been held close to the knee for periods up to half an hour, the experts on one side gave their opinion that such application showed negligence. On the other side, it was maintained that the tube never came nearer the knee than eight or ten inches, and from the radiographs produced in court, it was held by experts, that the distance of exposure must have been at least eight inches. The jury returned a verdict for the defendants on every count, finding that there was no negligence. This is the first suit in this country for damages for *x*-ray injuries. Great interest was taken in it, not only by surgeons conversant with *x*-rays, but by the public at large, and the demonstration of *x*-rays at work in the public court caused much excitement. In fact, I have not seen such a scene in court since on one occasion some ten years ago it became necessary in the progress of a libel suit arising out of a game of cards, for counsel to demonstrate the game of poker to the presiding judge by dealing hands all round.

LONDON LETTER.

The Fate of the Ovum and Graafian Follicle in Premenstrual Life.

At the Obstetrical Society of London Dr. T. G. Stevens read a most interesting and original paper on this subject. No writer appears to have investigated the retrograde changes of ova and graafian follicles in premenstrual life. Dr. Stevens' researches are based on the examination of upward of 70 pairs of ova, obtained in the postmortem room, of children at various ages, but always under the age of 10, so as to exclude the influence of menstruation. To get satisfactory sections great pains had to be taken in hardening. The ovaries were fixed whole in a saturated solution of corrosive sublimate, and the hardening was completed in alcohol of various strengths beginning with 30 per cent. and ending with absolute alcohol. Dr. Stevens found that rupture of the graafian follicles never took place and that nothing approaching the formation of a corpus luteum occurred. The follicle and ovum mature up to a certain point, and then a kind of phagocytosis takes place by which they are destroyed. The youngest graafian follicle, which may be termed a dormant follicle measures about .0325 mm., this measurement being practically that of the ovum as the covering of the follicle consists of only flattened cells closely applied to the ovum. In the next stage of development these flattened cells proliferate and become cubical, forming the membrana granulosa. Around this the cells of the ovarian stroma become concentrically arranged and form the fibrous tunic of the follicle. Liquor folliculi then appears among the cells of the membrana granulosa. These further proliferate and form the discus proligerus. At the stage of highest development in the child the follicle is .8 mm. in diameter and the ovum is .1 mm. (half that of the adult). Retrograde changes consist in the invasion of the ovum by phagocyte cells which appear to be derived from the cells of the membrana granulosa. Other cells of this layer disintegrate without further change. Eventually granulations form in the fibrous tunic and absorb the remains of the membrana granulosa and liquor folliculi. Discussing the rationale of these changes, Dr. Stevens points out that the ovary has two functions—the production of ova and of some internal secretion necessary to the health of the female up to a certain age. The supply of ova is unnecessary in childhood, and so the follicles do not burst, but probably the internal secretion plays an important part in the development of the female child. These constant changes in the graafian follicles may be the source of this internal secretion.

Abscess of the Uterine Wall in a Woman Suffering from Gonorrhea at the Time of Labor.

At the Obstetrical Society Dr. A. Lea described the case of a woman who had gonorrhea at the time of delivery and suffered during the second week after it from severe recurrent pain in the hypogastrium, but was able to walk about. Six weeks after delivery she was suddenly seized with intense abdominal pain, followed by symptoms of acute peritonitis. Laparotomy revealed an abscess in the posterior wall of the fundus uteri, which had ruptured into the peritoneal cavity. The abdomen was irrigated and abdomino-vaginal drainage was established by a large tube. The abscess cavity and the floor of the pelvis were packed with iodoform gauze. Recovery followed. Uterine abscess is rare. In many cases perforation has taken place into the peritoneal cavity when operation was not performed. Diagnosis is often difficult. Pain associated with great sensitiveness and enlargement of the uterus should arouse suspicion, but it is often difficult to distinguish the condition from infected myoma of the uterus. If perforation occurs immediate abdominal section is indicated. If the abscess is single and one or both appendages are normal conservative surgery should be carried out. If the uterus is infiltrated with pus hysterectomy should be performed. If the uterus is not removed drainage is necessary.

Septic Arthritis of the Ankle After Mumps.

At the Glasgow Eastern Medical Society Dr. J. W. Findlay described a case of mumps in which the very rare complication of arthritis occurred. The illness lasted a week, and the temperature was never over 100. When convalescence appeared about to be established a diffuse red swelling was found in the region of the left ankle-joint. The child became ill and the temperature rose to 102. Dr. Findlay diagnosed erysipelas. Three days later he opened what seemed to be a superficial abscess below the external malleolus. Later crepitation was detected in the joint. It was opened on its inner and outer aspects. Granulation tissue, débris and small fragments of cartilage were scraped away with a sharp spoon and the joint was douched and packed with iodoform gauze. After two days a drainage tube was passed through the joint and retained for a week. Then the wounds were allowed to heal. Five months after operation movements of the joint were only slightly limited. Osler mentions arthritis among the complications of mumps.

Latin as the International Language of Medicine.

The variety of languages which exists is a great obstacle to the spread of knowledge, and the need for a universal international language has often been declared. Attempts have been made with indifferent success to provide an artificial language, such as Volapük or Esperanto. The value of the ancient languages, Latin and Greek, for this purpose has also been discussed. In the volume of the Pathological Society's Transactions just issued Mr. Shattock has made a bold attempt to solve the difficulty by prefixing summaries in Latin to his three papers. In very comprehensible, if not classical, Latin he declares that it was a serious mistake that the Latin tongue was not retained as a medium of communication for those who devote themselves to the study of natural science. How grievous was the mistake is evident to all now that the number of languages used by those who write on natural science. Hence no one can know everything written on a subject however accurate be the references given in catalogues. As the Latin tongue is almost a necessary part of a liberal education he advocates its use. A paper on "The Fatty Vacuolation of the Nucleus in Fat Cells" is thus termed: *"De Vacuolatione nuclei in Cellula Adiposa."*

A Revaccination Bill.

The Imperial Vaccination League has drafted a revaccination bill for introduction into parliament in the present year. It is proposed that children shall be revaccinated within six months of attaining the age of 12. The clause which exempts parents having a "conscientious objection" from penalties for failing to comply with the act for the primary vaccination of their children also appears in this bill.

The Institutional Treatment of Inebriety.

At the Society for the Study of Inebriety Sir W. J. Collins, surgeon to the London Temperance Hospital, and formerly chairman of the Inebriates Acts Committee of the London County Council, delivered a most interesting address on the "Institutional Treatment of Inebriety." He described the measures taken by the very progressive London County Council to treat habitual drunkards. In 1879 the first legislative recognition in this country was accorded to the habitual drunkard, who was defined as a person who, not being amenable to any jurisdiction in lunacy, is in consequence of habitual intemperance dangerous to himself or to others and incapable of managing his affairs. Licensing authorities and "retreats" were recognized. Entrance to the latter was voluntary, though once there the volunteer becomes a prisoner for the period specified. This act, though amended in 1888, did not prove a conspicuous success. The reasons were want of compulsory powers to secure the admission of dangerous and confirmed inebriates, insufficiency of the maximum period of detention (13 months), difficulties with refractory patients, escapes, etc. Accordingly in 1893 institutional treatment was provided for in certified state reformatories, supplementing the voluntary retreats. The act also enabled magistrates to substitute reformatory treatment for imprisonment of habitual drunkards who had committed crime while intoxicated or who by repeated appearances for certain scheduled offenses connected with drunkenness had shown the inefficiency of short imprisonments. Thus there are at present "retreats" which receive private patients who have made requests but who do not sign away their liberty by any form, and which also receive those who submit to compulsory detention for a period not exceeding two years, certified inebriate reformatories established by local authorities receiving cases sent by magistrates, and the more severe state inebriate reformatories which receive the more criminal offenders or those for whom the lenity of certified reformatories has been found useless. The London County Council was the first municipal body to establish a certified reformatory. It purchased an estate in Surrey consisting of 374 acres with two mansions for $65,000. Some $35,000 were spent in adapting the estate and buildings for the accommodation of 30 female patients. The demand for accommodation grew rapidly, and in November a new building, adapted for 80 additional patients in six blocks, was erected at a cost of $115,000. Each patient has a separate bedroom, brightly furnished. A picturesque flower garden with lake and lawn adjoins the old mansion house. At the home farm, a quarter of a mile off, is a model dairy where the better-behaved are instructed in butter-making, baking, etc. Caring for poultry and bees, fruit-farming, potato picking, weeding and haymaking are among the outdoor duties of the women. Everything is done to take the patients back to the simple natural life of the English country homestead. A system of marks has been arranged whereby the women are enabled to earn something against their time of departure. There are punishment cells, spacious and light, resorted to only when moral suasion is exhausted.

The Health of London.

The report of Dr. S. F. Murphy, health officer to the county council for 1902, has just been issued. A most gratifying feature of the report is that, thanks to the untiring efforts of the Public Health Committee, London becomes more healthy year by year. The death rate for 1902 was only 17.2 per 1,000—the lowest on record except that for 1901, which was 17.1. The birth rate continues to steadily decrease, that for 1902 being 28.5—the lowest on record.

Correspondence.

The Duration of Life After Fatal Injuries.

San Francisco, Feb. 20, 1904.

To the Editor:—The question as to how long a patient may live after the reception of necessarily fatal injuries is just now the subject of judicial inquiry in the noted Fair case. In this particular trial the point at issue is whether Charles Fair or his wife lived the longer after receiving the severe injuries to the head that were disclosed by the autopsy. So far as gross lesions are concerned it would appear that Mrs. Fair's injuries were the more severe, the frontal bone being crushed and brain tissue lost. On this ground one of the medical witnesses very confidently asserted that Mrs. Fair must have died first. Apart from the fact that vital resistance is an unknown quantity in any given case, and that some individuals, such as those possessed of the so-called status lymphaticus, may instantly die as the result of the most inadequate causes, it is also apparent that quality and not quantity of tissue must be the determining factor in stopping the vital functions, a very small lesion in the neighborhood of the cardiac and respiratory centers being much more serious than a most extensive laceration of the frontal lobes. Rather curiously, lesions of the medulla and fractures of the base of the skull were not looked for in the case of Charles Fair. My object, however, in writing is to record a case that occurred in my practice some thirteen years ago, and to which I have often referred in private and to my class, but which I did not deem of sufficient importance until I read the medical opinion in the Fair case, with which this experience is entirely at variance.

A child, between one and two years of age, fell out of a baby carriage and rolled under the wheels of a heavily laden two-horse omnibus. The accident occurred in front of my house and the child immediately was brought in. The entire front of the head was crushed. The left temporal and frontal bones were torn from their anterior attachments, in a line running through the center of the orbit; in this way the vault of the skull was pried off the face, leaving an immense wound, through which at least a third of the brains had escaped into the roadway. As the child was carried into the hallway it uttered low cries, which, however, immediately ceased, but the breathing continued fairly regular for some time, as was the pulse. Final stoppage of the heart and respiration did not occur until twenty minutes after the receipt of the injury. I have always attributed this remarkable persistence of life to the probability that the basic ganglia were uninjured, and that notwithstanding the extent of the injury the loss of blood was not so great.

H. D'Arcy Power.

Significance of the Weight Wave of Menstruation.

Chicago, Feb. 24, 1904.

To the Editor:—As supplemental to my article on this subject in The Journal, June 13, 1903, allow me to report:

1. The increase in weight preceding the menstrual flow—which may exceed one pound per hour for several hours, the total increment being sometimes seven to nine pounds in 24 hours—is due to (*a*) increased absorption of oxygen, and (*b*) decreased excretion, notably of carbon dioxid and water. (Increased pressure of oxygen in the blood has been shown by Paul Bert, Hill and Macleod to retard metabolism and to decrease the excretion of CO_2 and water.)

2. The essential phenomena of the menstrual weight wave are therefore (1) the rapid absorption of oxygen with coincident retardation of metabolism and excretion, and consequent increase in weight; and (2) rapid excretion, especially of carbon dioxid (the exhalation of which may exceed two pounds in one hour) with consequent rapid decrease in weight.

3. Many observations, to be elaborated later, warrant the deduction that a cause of this metabolic cycle is an ovarian product; and that the menstrual discharge, white as well as red, proceeds from glandular activity of the uterus and is a feature of the general excretory activity of this period.

William T. Belfield, M.D.

Optional Medical Course in Liberal Arts School.

Chicago, Feb. 29, 1904.

To the Editor:—Knowing that The Journal is interested in anything that tends to best equip the physician for his profession, I wish, as an alumnus and member of the board of trustees of Wabash College—one of the oldest literary colleges in the middle west—to state through The Journal the following optional course of study which has recently been adopted by this institution for students who propose entering professional schools:

> A four years' course of study in which three years shall be prescribed work, all electives being reserved for the fourth year. Students taking this option will be permitted, if they so desire, to pursue their fourth year in attendance at a professional school approved by the trustees of the college; retaining in the meantime their college standing and responsibility and being eligible to graduation with their class on presentation of proper credits earned in this way.

Other options, of course, are given by the college in the way of allowing the elective work to be so arranged as to make the most advantageous connection with certain professional schools should the student desire to remain the full four years. The adoption of the foregoing optional course makes it of benefit to the student as well as to the college and, further, to the medical profession, should the student choose medicine as his profession. It so governs and directs the student as to guarantee for him the best education the profession offers. It gives the medical profession a more skilled and better prepared man, and the honor to the college will be reflected by the work accomplished in a professional way by this alumnus.

Geo. W. Hall.

Actinic Rays.

New York City, Feb. 22, 1904.

To the Editor:—Albert E. Sterne, A.M., M.D., has used some terms in his paper "Neurasthenia and Its Treatment by Actinic Rays" which I think should be corrected. This paper has been read before the American Medical Association and has been approved for publication by the Executive Committee of the Section. In medicine we are not bound to rely on authorities, and I for my *part do not* approve the title of that paper. 'Η ἀκτίς is the ray, actinic ray would then be rayish rays, but that is nonsense according to my understanding. I have not studied the paper *in* question thoroughly, but at a glance I notice on *page* 501 *some* remarks on one form of hysteria characterized by what the French termed "*Grandes movements.*" In Dr. Sterne's paper these two words are given with quotation marks and printed in italics, exactly as I give them here. There is no such word in the French language as movement or movements. Of course, Dr. Sterne means *mouvement*, but *this* is a masculine, the French term would therefore be "*Grands mouvements.*". I think it is very important to correct such mistakes, because they are transmitted by those who do not know better than the originator.

A. Rose.

Queries and Minor Notes.

Anonymous Communications will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the *request* of the writer not to publish his name will be faithfully observed.

CHARGES FOR SERVICES TO PHYSICIANS AND THEIR FAMILIES.

Colorado Springs, Colo., Feb. 18, 1904.

To the Editor:—I write for information. What is the present status of the profession as regards rendering bills and accepting fees from physicians, and from their families, for services rendered? A recent personal experience pleads my excuse for enlightenment.

My eldest daughter, at present at school in New York City, developed some scalp affection. I advised her to consult a certain dermatologist, a man of some repute; a man with whom I was personally acquainted, whom I had entertained in my home, and a man to whom I have referred many New York friends. My daughter also induced a wealthy girl, one of her school friends, suffering from some skin trouble, to consult this man. January 1 I received a bill from this doctor for "Thirty dollars, less fifteen," the discount presumably owing to my being in the profession. I at once remitted the full amount, "Thirty dollars," and notified the doctor that he was very kind, but that I could not think of accepting his discount.

I have practiced here for the past thirty years, and during that time have attended hundreds of physicians and their families. I have always cheerfully responded, night or day, and have always felt it would be a personal insult if a physician requested a bill for services. From the above experience I have evidently been in the wrong. Your opinion and the opinion of the decent men in the profession would be valuable. B. P. Anderson, M.D.

Answer.—Our correspondent's custom of cheerfully rendering services to physicians and their immediate families without charge is the custom of the majority of physicians. Is it possible that the charge in this case was made by inadvertence or misunderstanding? The Principles of Ethics says:

"All practicing physicians and their immediate family dependents are entitled to the gratuitous services of any one or more of the physicians residing near them."

"When a physician is summoned from a distance to the bedside of a colleague in easy financial circumstances, a compensation, proportionate to traveling expenses and to the pecuniary loss entailed by absence from the accustomed field of professional labor, should be made by the patient or relatives."

DECISIONS UPHOLDING COMPULSORY VACCINATION LAWS.

Roanoke, Va., Feb. 15, 1904.

To the Editor:—For the benefit of those concerned in prosecuting persons for resisting compulsory vaccination, will you kindly give references in the standard law reports to decisions of the supreme courts in the various states where the constitutionality of compulsory vaccination and re-vaccination law was upheld? For instance, what is the reference in the law reports to the cases in Georgia and North Carolina mentioned in The Journal A. M. A., vol. xl, No. 22, p. 1533?

Frederic B. Webb, M.D.

Answer.—Morris vs. Columbus, 102 Ga. 792; State vs. Hay, 126 N. C. 999; Levin vs. City of Burlington (N.C.) 39 S. E. 822 or 55 L. R. A. 396.

LOSS OF TASTE AND SMELL FROM FORMALIN DISINFECTION.

Bakersfield, Cal., Feb. 24, 1904.

To the Editor:—During December I had several cases of scarlet fever, on which I had to call two and three times a day, and after each visit I went to my office and disinfected myself with formalin vapor. After the first week I noticed that I could stay in the room for a much longer time before it would seemingly irritate my nose or eyes. As a result, my sense of smell is entirely gone and everything I eat or drink tastes like formalin. I am unable to find, from the literature on formalin or from inquiry of my brother practitioners, what I can do to regain my sense of smell. If there is any article on this subject that you know of I wish you would cite it to me. If not, please put the question in The Journal and perhaps some one may have something to say through the columns of The Journal that will throw some light on this very annoying affliction. J. L. Carson, M.D.

Marriages.

Hugh Wilkinson, M.D., to Miss Ethel Sims, both of Kansas City, Kans., February 21.

Dudley Tait, M.D., San Francisco, to Miss Carrie Cozzens of San Jose, Cal., February 17.

Herbert B. Hanson, M.D., Hinesburgh, Vt., to Miss Myrtle S. Joy of Barre, Vt., February 16.

Joseph R. Hawley, M.D., Chicago, to Miss Daisy Miller of Muskegon, Mich., February 11.

William H. Tucker, M.D., Eldorado, Ohio, to Miss Grace W. Hill of Glen Karn, Ohio, February 21.

George H. Wollgast, M.D., to Miss Lucylle E. Hathaway, both of Coffeyville, Kans., Dec. 24, 1903.

Arthur E. Vinton, M.D., Muncie, Ind., to Miss Florence Lucille Nixon of Fountain City, Ind., February 16.

Earle Hoopes Ingham, M.D., to Miss Josephine R. B. Davis, both of Philadelphia, at Wilmington, Del., February 9.

William H. Raymenton, M.D., Worcester, Mass., to Miss Grace Lillian Carr of Pasadena, Cal., at Watertown, Mass., February 21.

Deaths.

Franklin Staples, M.D., died at his home in Winona, Minn., February 22, from locomotor ataxia after a lingering illness, aged 70. He studied medicine at Bowdoin Medical College and at the College of Physicians and Surgeons, New York, graduating from the latter in 1862. In the summer of this year he located in Winona. He was a charter member of the Minnesota State Medical Society, and at its third meeting was chosen president. He assisted at the organization of the Winona County Medical Society, and was its first secretary. He became a member of the American Medical Association in 1871, served as a member of the judicial council from 1875 to 1877, and was elected vice-president in 1877. In 1874 he was appointed a member of the Minnesota State Board of Health, and was elected president in 1879, and held this office until his death. From 1883 until 1887 he was professor of practical medicine in the medical department of the University of Minnesota when the faculty constituted the medical examining board of the state. Of late years Dr. Staples gave special attention to sanitation, his contributions in this field being numerous and eminently practical. He served as health officer of the city of Winona for many years, performing the arduous duties of that office in a manner not less creditable to himself than valuable to the community. Dr. Staples enjoyed the confidence and esteem of the medical profession throughout the Northwest, where he was widely known.

Gustav Liebmann, M.D. University of Tübingen, Germany, 1856, who practiced in Baltimore until 1881, and then moved to Boston, where he was a member of the school board, and from 1897 to 1900 professor of diseases of the digestive organs in the College of Physicians and Surgeons, died at his home in Brookline, Mass., February 20, aged 71.

John Dickenson, M.D. Cleveland Medical College, 1857, died at his home in Cleveland, February 19, aged 70. He served throughout the Civil War as surgeon, was health officer of Cleveland for several terms, and at one time surgeon of the police force.

John M. Minick, M.D. Cincinnati College of Medicine and Surgery, 1877, a member, and until January 1, president of the Kansas State Board of Health, died at his home in Wichita, February 22, after an illness of one week, aged 62.

Adolph Opperman, M.D. Germany, 1881, died at his home in Cordell, Okla., February 18, after a protracted illness, aged 61. He was the first physician to locate in Auburn, Neb., and was coroner of Nemaha County for several terms.

William B. Southard, M.D. University of Buffalo, 1859, at one time president of the Kalamazoo Academy of Medicine, died at his home in Kalamazoo, Mich., February 21, from paralysis, after an illness of eight days, aged 81.

Henry Rosenstock, M.D. Jefferson Medical College, Philadelphia, 1896, formerly of Philadelphia, who had been practicing for six weeks in Scranton, Pa., died at his home in Philadelphia, February 23, from Bright's disease.

Sebastian C. Dumm, M.D. Cleveland Medical College, 1872, Columbus, died at the Protestant Hospital, Columbus, February 19, from hemorrhage, a few hours after an operation for gallstones, aged 54.

William Alfred McCorn, M.D. University of Buffalo, 1882, formerly superintendent of the Elizabeth (N. J.) General Hospital, died suddenly at his home in Long Island City, N. Y., February 18.

James V. McLaughlin, M.D. College of Physicians and Surgeons, Baltimore, 1882, died at his home in Lisbon, Ohio, February 19, from consumption, after an illness of several months, aged 45.

August Krehbiel, M.D. University of Munich, Germany, 1878, a member of the consulting staff of the German Hospital, New York City, died at his home in New York City, February 11, aged 64.

Matthew Fletcher Haney, M.D. University of Buffalo, 1850, died at his home in Humberstone, Ont., Dec. 3, 1903, aged 79.

True M. Gould, M.D. Dartmouth Medical College, Hanover, N. H., 1855, for sixteen years postmaster of Raymond, N. H., died at his home in that place, February 15, aged 72.

August H. Trow, M.D. Castleton (Vt.) Medical College, 1862, in 1859, 1860 and 1872 a member of the Minnesota legislature, died recently at his home in Ethan, S. D., aged 81.

E. Graves Kittson, M.D. McGill University, Montreal, 1873; L.R.C.P. London, 1879, died at his home in Hamilton, Ont., February 4, after an illness of ten years, aged 52.

Thomas Nicholas Drake, M.D. University of Pennsylvania, Philadelphia, 1856, died at his home in Wilson, N. C., February 13, after a short illness, aged 74.

John Cooke, M.D. Cincinnati College of Medicine and Surgery, 1880, died at his home in Hastings, Neb., February 12, after an illness of eleven days, aged 58.

Evan W. Warfield, M.D. University of Maryland, Baltimore, 1845, died at his country place, Longwood, near Ellicott City, Md., February 17, aged 78.

Charles F. Alsentzer, M.D. University of Pennsylvania, Philadelphia, 1883, died at his home in Philadelphia, February 16, from heart disease, aged 38.

Peter Bryson Wood, M.D. Columbian University, Washington, D. C., 1883, died at his home in Baltimore, February 19, from pneumonia, aged 44.

Owen B. Canfield, M.D. Kentucky School of Medicine, Louisville, 1877, died at his home in Edgar, Neb., February 22, after a long illness, aged 48.

A. S. Martin, M.D. Lind University, Chicago, 1863, surgeon during the Civil War, died at his home in Cleveland, Ohio, February 15, aged 70.

H. William Burg, M.D. Jefferson Medical College, Philadelphia, 1877, of Northumberland, Pa., died at a hospital in Philadelphia, February 16.

Martin S. Leslie, M.D. Kentucky School of Medicine, Louisville, 1889, died suddenly at his home in Greenup, Ky., a few days ago.

Aimee R. Schroeder, M.D. Woman's Medical College of New York Infirmary, 1899, died in New York City, Dec. 25, 1903, aged 46.

Andre L. Cowles, M.D. University of Buffalo, 1892, died at his home in Spartansburg, Pa., February 18, from pneumonia, aged 60.

Joseph Atkins, M.D. Medical College of Ohio, Cincinnati, 1837, died at his home in West Lafayette, Ind., February 18, aged 92.

Stephen Eastman Root, M.D. University of Vermont, Burlington, 1875, died at his home in Rochester, N. H., February 12.

Carl H. Roese, M.D. Cooper Medical College, San Francisco, 1894, died at his home in San Francisco, December 12, aged 35.

Samuel D. Amerman, M.D., died at his home in Bartow, Fla., February 14, from heart disease, after a short illness, aged 57.

D. P. Rubush, M.D. Indiana, 1897, was found dead from heart disease at his home in Sharpsville, Ind., February 22, aged 56.

Whipple W. Clarke, M.D. Jefferson Medical College, Philadelphia, 1882, died at his home in Old Fort, N. C., February 15.

Albert A. Hanna, M.D. University of Maryland, Baltimore, 1875, died suddenly at his home in Baltimore, February 25.

Thomas Norton, M.D. McGill University, Montreal, 1874, died at his home in Shelburne, Ont., January 14, aged 52.

Green Moore, M.D. University of Louisville, 1874, died from paralysis at his home in McKinney, Ky., February 23.

Alvin R. Davis, M.D. Jefferson Medical College, Philadelphia, died at his home in Rawlins, Wyo., February 17.

D. M. Young, M.D. Ohio, died at his home in Painesville, Ohio, February 21, aged 85.

A. L. Ferrar, M.D., a pioneer of Petaluma, Cal., died January 15, aged 78.

Book Notices.

Social Diseases and Marriage. Social Prophylaxis. By Prince A. Morrow, A.M., M.D., Emeritus Professor of Genito-urinary Diseases in the University and Bellevue Hospital Medical College, New York. Cloth. Pp. 390. Price, $3.00 net. New York and Philadelphia: Lea Brothers & Co. 1904.

The work before us is timely. It deals with a subject which has to be handled delicately and yet thoroughly to be of use, and the author has certainly succeeded in meeting both these requirements. Every page of the text shows that it has been written by one who knows whereof he speaks. It is a pity that a book like this must be restricted to professional reading, but the physician who possesses it will find in it many points and hints that he can disseminate to his clientele to the very best advantage. A very interesting point discussed is that of the medical secret in regard to venereal disease. The author appears to us to take a judicial position, though he is evidently not too anxious to pronounce a decided opinion. In these days when there is so much agitation to have medical privilege established by law it is well to consider the situation in which the physician may find himself, and which is so well portrayed in this work. If it is the law for a physician to prevent a prospective crime the question of privilege in these cases is certainly not a dubious one. Of course, unnecessary publicity can be avoided and the absolute restrictions made at the present time by the French laws, and we believe also by one or two states of the Union, appears to us not only a moral wrong, but absolutely dangerous to society.

The Praxis of Urinary Analysis. A Guide to the Chemical Analysis of Urine. With Directions for Preparing Artificial Pathologic Urines for Practicing the Various Tests, and an Appendix on the Analysis of Stomach Contents. By Dr. Lassar-Cohn, Professor in the University of Koenigsberg. Authorized Translation from the Author's Enlarged and Revised Second Edition. By H. W. F. Lorenz, A.M., Ph.D. (Berlin), Late Instructor of Organic Chemistry in the University of Pennsylvania. First Thousand. Cloth. Pp. 58. Price, $1.00. New York: John Wiley & Sons. London: Chapman & Hall. 1903.

This little book, which seems to have a high standing in its own country, will be something of a surprise to many medical students and practitioners in the positiveness with which the author speaks of the uselessness of multiple tests and the advantages of a single one. Thus for albumin he gives only the heating test. For sugar, Trommer's test, etc. He does not include among the abnormal constituents of urine, uric acid and some other substances which are often considered necessary to be sought for either by qualitative or quantitative analyses. So far as it goes, however, the book is a reliable guide.

The Blues (Splanchnic [illegible]d Cure. By Albert Abrams, A.M., M.[illegible], Consulting Physician Denver National [illegible] Illustrated. Pp. 240. Price, $1.50. New York: E. B. Treat & Co. 1904.

The object of the author, he states in his preface, is to call attention to a new and heretofore underscribed variety of nerve exhaustion, which he designates as splanchnic neurasthenia, characterized by paroxysms of depression of varying duration, popularly called "the blues." Fortunately his experience with the condition has taught him that there is no variety of neurasthenia more amenable to treatment than this splanchnic form. The relation of emotional conditions to the abdominal viscera was recognized almost from the earliest antiquity. Depression of spirits and disease below the diaphragm have always been considered as associated, but Dr. Abrams has here brought out a scientific theory and statement of the condition.

Diseases of the Nose and Throat. By Charles Huntoon Knight, A.M., M.D., Professor of Laryngology, Cornell University Medical College. With 147 Illustrations. Cloth. Pp. 423. Price, $3.00 net. Philadelphia: P. Blakiston's Son & Co. 1903.

This work is based on a course of lectures at the Cornell University Medical College, and its arrangement is such as to make it suited for the use of students. Only the essentials of anatomy are described, the details, as the author says in his preface, can be found in more extensive and special works. The treatment of the different forms of disorder are clear and appear to us thoroughly satisfactory. The illustrations are numerous and instructive. The positions taken by the author in matters open to any question are judicious. As a whole the work is an admirable general summary of the subject of nose and throat diseases in a convenient compass and well suited for students' use.

Elements of Surgical Diagnosis. By A. Pearce Gould, M.S. Lond., F.R.C.S. Eng., Surgeon to the Middlesex Hospital. Third Edition. Revised and Enlarged. Cloth. Pp. 607. Price, $2.00 net. Chicago: W. T. Keener & Co. 1903.

This little work has been thoroughly revised and considerably rewritten for this edition. Certain sections have been added, such as those on the diagnosis of intracranial complications of middle ear disease and on the diagnosis of abdominal tumors. It also includes modern acquisitions in bacteriology, blood examinations, etc. We notice, however, a few omissions, for example, the surgery of typhoid fever; this is not a new subject, but appears to have been overlooked.

THE PRINCIPLES AND PRACTICE OF SURGERY. Designed for Students and Practitioners. By George Tully Vaughan, M.D. (Univ. of Va.), Assistant Surgeon-General U. S. Public Health and Marine-Hospital Service. Cloth. Pp. 568. Price, $3.50. Philadelphia and London: J. B. Lippincott Company. 1903.

In this volume of a little over five hundred pages practically the entire field of surgery is covered. That it could be covered in that space in only the most superficial manner goes without saying. The text is so condensed that it frequently amounts to little more than mere definitions. The student could obtain from the work a good general idea of what he was expected to study, but as a rule sufficient detail is lacking to guide the general practitioner in his work.

THE DECENNIAL PUBLICATIONS, University of Chicago. The Distribution of Blood-vessels in the Labyrinth of the Ear of Sus Scrofa Domesticus. By George W. Shambaugh, Instructor in the Anatomy of the Ear, Nose and Throat. Printed from Vol. X. Paper. Price, $1.25. Chicago: The University of Chicago Press. 1903.

This monograph is an elaborate description, beautifully illustrated, of the circulation in the labyrinth of the pig's ear. The author describes his methods and findings in detail and sums up the points of special interest. The work is an interesting and practical contribution to special anatomy and gives evidence of most painstaking and thorough investigation of its subject.

CLINICAL EXAMINATION OF THE URINE AND URINARY DIAGNOSIS. A Clinical Guide for the Use of Practitioners and Students of Medicine and Surgery. By J. Bergen Ogden, M.D., Formerly Instructor in Chemistry, Harvard University Medical School, Boston. Second Revised Edition. Illustrated, Including 11 Plates; 9 of Them in Colors. Cloth. Pp. 418. Price, $3.00 net. Philadelphia, New York, London: W. B. Saunders & Co. 1903.

This is a useful general treatise on urinary analysis. The author has made a few changes in regard to certain tests and taken up one or two subjects that were not noticed in the former work, such as cryoscopy. Otherwise the book, in the main, is the same as the former edition.

THE NUTRITION OF THE INFANT. By Ralph Vincent, M.D., Member of the Royal College of Physicians. Cloth. Pp. 295. Price, $3.50. New York: William Wood & Co. 1904.

Works on infant feeding are one of the necessities of the present day and are essential to every working physician's library. Dr. Vincent has prepared a treatise which, while it may not supersede other works like those of Judson and Gittings, nevertheless will be found useful as covering the same points in perhaps a somewhat different way. The author's dedication to Dr. Thomas Morgan Rotch shows how much he recognizes what is due to American work in this line.

A TEXT-BOOK OF MODERN MATERIA MEDICA AND THERAPEUTICS. By A. A. Stevens, A.M., M.D., Lecturer on Physical Diagnosis in the University of Pennsylvania. Third Edition. Greatly Enlarged, Rewritten and Reset. Cloth. Pp. 663. Price, $3.50 net. Philadelphia: W. B. Saunders & Co. 1903.

In this edition Stevens has rearranged the classification and rewritten the work to bring it up to the modern advances of the subject.

Miscellany.

Medicine for the Physician.—"Wholesome exercise, in the free air, under the wide sky, is the best medicine for body and spirit." This truism is again recommended for the hospital interne and the city physician whose practice is largely limited to office consultations.

A Dirty Office.—The *Medical Recorder* (Shreveport, La.) urges physicians to set an example for cleanliness and have neat offices. It says: "The average physician's office, especially in the country villages, usually looks as though it had not had a good cleaning for months."

Rubber and Linen Gloves.—A German journal recommends the use of linen gloves drawn over rubber gloves during an operation. The instruments do not slip as easily on the linen and do not puncture it, while the rubber beneath prevents the escape of germs from the skin. Is this a good suggestion or is this carrying the matter of gloves too far? Is not the surgeon's skilled sense of touch one of his most valuable accomplishments? If not, a modified form of boxing gloves would absorb the germs from the skin and prevent infection.

Exhibit of Medical Journals at the St. Louis Fair.—The editorial fraternity will be much interested in the proposed exhibit of medical journalism at the St. Louis Exposition this summer. Several of our contemporaries have commented on this matter, expressing the value of such an exhibit. In a special department all the medical publications of the State of Missouri are to be exhibited. Space has been allotted in the Palace of Liberal Arts, and Dr. Charles Wood Fassett of St Joseph, Mo., is in charge of the exhibit. There will be much instruction in an examination of this exhibit.

The Contagiousness of Scarlet Fever.—An interesting item is going the rounds of the medical press, in which comment is made on an article which was abstracted in THE JOURNAL two years ago. Aaser of Christiania, finding many cases of scarlet fever infection from nose and throat secretions after desquamation had entirely ceased, urged that this source of infection be more carefully guarded against. It is well to give general publicity to this caution and to ask for further observations, but in these two years doubtless Aaser can add some facts to those given at the time of his original publication.

A Medical Professor of Anatomy in Art.—Dr. P. Richer of Paris is an accomplished sculptor, whose works have won him many medals. His literary articles on anatomy and pathology in art and on various art questions have been doubly crowned with prizes, one from medical and the other from art societies. Last year he was appointed professor of anatomy at the school of fine arts, the famous "Beaux-Arts," and his methods of teaching are effecting a revolution in the routine of art instruction. He has the students draw first the bones, then the muscles, separately, and then he has them draw them in place from the live model. The students thus learn anatomy with their crayon in hand, as the medical student learns it with the knife.

Pithy Papers.—The editor has attended several meetings for the organization of county societies, and has been struck by one thing more particularly than any other—the desire of the physicians to get together to form such societies, to omit the long, tiresome papers compiled from text books or journals, and to confine the work of the society meetings to short, pithy papers or reports that deal with practical questions and actual experiences. That is just what we all really need. Some men seem to have the diabolic faculty of putting together a mass of stuff making a paper of great length, which is painful even for the printer to read, when everything that they had to say could have been said in one-tenth of the space.—*California State Journal of Medicine.*

Physical Development of Mexican Children.—R. Carrillo publishes in the *Revista Medica*, XIV, Nos. 12 to 18, the results of examination of several hundred children among the lower classes of the city of Mexico. He found only a single instance of rachitis among 500 examined. The size and weight of the children, from birth to the sixth year, is less than the corresponding figures for the European child. The teeth do not develop so early; dentition extending over thirty-six months in extreme cases, the average being thirty months, while in Europe the average is eighteen months, with twenty-four as the extreme. Co-ordinated movements commence at about the same age in both Mexican and European children, apparently not influenced by the backward development of the former. He gives detailed tables of the various groups of children examined.

Medical Societies to Cross-Examine So-called Experts.—Would the expert evidence in the trials be just what it is if the medical societies were in the habit of calling their members to the bar of an expert public opinion and demanding that they state, fully state, all the evidence, facts and symptoms, which they found, and the reasoning by which they reached the conclusion which they have embodied in their testimony as experts? Imagine the state of mind of two practitioners who have testified on the opposite sides of some damage suit if they were obliged to file with the court a statement of the symptoms and objective evidence on which they based their opinions, and if after the trial and verdict this were sent to the medical examining board of the state, and then the experts were called on to explain. If this thing were to happen about twice, would not a change wonderful to contemplate come over the "expert medical testimony" given in such damage suits?—*Medical Examiner and Practitioner.*

Professional Charges—The Patient's Ability to Pay.—It is often difficult for the physician to make his charges equitable on the basis of the financial condition of the patient. Dr. Ernest A. Hall, Vancouver, B. C., suggests to the *Dominion Medical Monthly* a table as a guide for fees. He intends this schedule to apply only to patients in moderate circumstances, and when the income reaches $200 per month he recommends that the amount of the fee be left wholly to the discretion of the physician, but the table could be extended to include all amounts. In the first column the figures represent in dollars the income of the family or of the patient. At the top of the other columns the numbers, 1, 2, 3, etc., indicate the number of persons dependent on the income, and the figures in the columns below are percentages. These percentages indicate what proportion of the usual fee should be charged. For example, if $100 would be the regular charge for a certain series of visits or for a certain operation for which a man with a salary of $120 per month is to pay, he having a wife and five children, opposite the monthly income of $120, in the column under 7 (man, wife and five children made a total of 7 dependent on the income) is found the percentage of 60. Taking 60 per cent. of $100 gives $60 to be charged. Thus the table establishes a ratio between the income and the number dependent thereon, or, in other words, the assets of the family are divided by the liabilities, and thus is derived that most important fact—the ability to pay. The table may be subject to a number of criticisms, but we reproduce it herewith for whatever suggestiveness or value it may have for our readers.

Monthly Income.	Number Dependent on Income.								
	1	2	3	4	5	6	7	8	9
$150.	100%	100%	100%	100%	100%	100%	90%	80%	70%
140.	100	100	100	100	100	90	80	70	60
130.	100	100	100	100	90	80	70	60	50
120.	100	100	100	90	80	70	60	50	40
110.	100	100	90	80	70	60	50	40	30
100.	100	90	80	70	60	50	40	30	20
90.	90	80	70	60	50	40	30	20	10
80.	80	70	60	50	40	30	20	10	
70.	70	60	50	40	30	20	10

40.	40	30	20	10					
30.	30	20	10						
20.	20	10							
10.	10								

Lay Opinions on Malpractice.—In the malpractice suit against Dr. Burrows of Marshalltown, says the *Iowa Medical Journal*, Judge Burnham, in taking the case away from the jury, had the following to say: "I think the plaintiff and her husband should rise up and bless this man for having saved the life of the plaintiff in this case. The evidence here clearly shows this defendant has exercised the greatest care and the greatest caution, and has brought to bear skill at least equal to what is required of physicians of the community in which he practices. I can not sit here and say this defendant has been guilty of conspiracy with his brother physicians to protect himself against a claim made in this case. I do not believe it." The editor of the city paper in commenting on the verdict makes some pertinent remarks that are worth preserving, thus: "As a general rule damage cases against reputable physicians and surgeons for malpractice will fail to materialize evidence whenever they appear in court, and the action of Judge Burnham this week will be approved by the public generally. The profession of surgery is a life-saving business. It would be a calamity if the surgeons should quit operating, and it follows that if a surgeon or physician is known to be practicing his profession with success in a majority of cases, he should not be mulcted for damages, even though an operation should fail or a patient be dissatisfied. He does not guarantee success and should not be held for anything except incompetence or criminal neglect. Anything else would be asking a practitioner to assume risks far in excess of the premiums to be derived from his business, and the public welfare would not be favored by a raise in doctors' rates to insure such risks. However, the provisions of the law are very necessary for the protection of the public from the criminal incompetency of the quack, hence it remains largely with the good judgment of the court to see that justice is done, a duty that Judge Burnham seems to have discharged with ability."

State Boards of Registration.

COMING EXAMINATIONS.

Board of Registration in Medicine for Massachusetts, State House, Boston, March 8-9. Secretary, Edwin B. Harvey, M.D., State House, Boston.

Committees of Examination of Connecticut, New Haven, Hartford and Waterbury, March 8. Secretary, Prof. C. A. Lindsly, New Haven.

Maine Board of Registration of Medicine, Portland, March 23. Secretary, A. K. P. Meserve, M.D., Portland.

Regular Board of Medical Examiners for Georgia, Atlanta, March 30. Secretary, I. H. Goss, M.D., Athens.

State Board of Examiners of Alabama, Montgomery, 1st to 10th of each month. Chairman, W. H. Sanders, M.D., Montgomery.

Arizona Board of Medical Examiners, Phoenix, April 4. Secretary, Wm. Duffield, M.D., Phoenix.

Utah State Board of Medical Examiners, Salt Lake City, April 4. Secretary, R. W. Fisher, M.D., Salt Lake City.

Board of Medical Examiners of Montana, Helena, April 5. Secretary, Wm. C. Riddell, M.D., Helena.

North Dakota State Board of Medical Examiners, Grand Forks, April 5. Secretary, H. M. Wheeler, M.D., Grand Forks.

Board of Medical Examiners of the State of California, City Hall, San Francisco, April 5. Secretary, Geo. G. Gere, San Francisco.

Idaho State Board of Medical Examiners, Boise, April 6. Secretary, R. L. Nourse, M.D., Hailey.

Minnesota State Board of Medical Examiners, State Capitol Building, St. Paul, April 5-7. Secretary, C. J. Ringnell, M.D., Minneapolis.

Rhode Island State Board of Health, State House, Providence, April 7-8. Secretary, Gardner T. Swarts, M.D., Providence.

State Medical Board of the Arkansas Medical Society, Little Rock, April 12. Secretary, J. P. Runyan, M.D., Little Rock.

Missouri State Board of Health, Kansas City, April 12-14. Secretary, W. F. Morrow, M.D., Kansas City.

West Virginia State Board of Health, Clarksburg, April 12-14. Secretary, Hugh A. Barbee, M.D., Point Pleasant.

Vermont State Board of Medical Censors, Y. M. C. A. Building, Rutland, April 13-14. Secretary, S. W. Hammond, M.D., Rutland.

Board of Medical Supervisors of the District of Columbia, Washington, April 14. Secretary, Wm. C. Woodward, M.D.

Board of Medical Examiners for the State of Texas, Austin, April 21-23. Secretary, M. M. Smith, M.D., Austin.

No Reciprocity Between New York and Pennsylvania.—The Medical Council of Pennsylvania, at its session in Harrisburg, Feb. 13, 1904, took the following action:

> Whereas, On careful examination, we find that the standard of acquirements of the medical examination of the State of New York is not substantially the same as that of the medical examination of the State of Pennsylvania; therefore, be it
>
> *Resolved*, 1. That on account of the disparity existing as to the acquirements in the states of New York and Pennsylvania, New York licenses shall not be accepted as the authority for granting Pennsylvania licenses under the provision of the act approved May 18, 1893.
>
> *Resolved*, 2. That a copy of this action be sent to The Journal of the American Medical Association and to the dean of each medical college in the State of Pennsylvania.

California Report.—Dr. George G. Gere, secretary of the Board of Medical Examiners of the State of California, reports that 90 questions were asked on 9 subjects in the written examination given at San Francisco, Dec. 1-3, 1903, and that out of 68 applicants, 46 passed, 5 were conditioned and 17 failed entirely. The percentage required was 75. The questions are given below. The colleges named below were represented by applicants who were graduates in the years stated, and who received the grades stated. There was also a licentiate of the Illinois State Board of Health of the year 1898, who received a grade of 83.2.

PASSED.

Colleges.	Years of Graduation and Grades
University of California,	(1900) 84.1, (1902) 86.1, (1903) 76.7, 83.4, 83.1.
College of P. and S., San Francisco,	(1903) 89.8, (1902) 78.8.
Cooper Med. Coll., San Francisco,	(1903) 78.5, 75.4, 83.5, 78.3, 77.3.
Hahnemann Med. Coll., California,	(1903) 82.3, 80.7, 81.5, 77.6, 81.7, 77.2.
Northwestern Univ., Chicago,	(1902) 82.3, (1903) 83.4, 80.1.
Coll. of P. and S., Chicago,	(1903) 83.8, (1901) 77.1.
University of Pennsylvania,	(1889) 80.3, (1893) 91.3, (1900) 84.8.
University of Michigan,	(1901) 83.4, (1894) 82.5.
Harvard University,	(1902) 82.6, (1891) 84.7.
University of Iowa,	(1883) 75.4, (1896) 77.1.
Detroit College of Medicine,	(1876) 75, (1902) 78.1.
University of Minnesota	(1903) 75.5
University of Southern California	(1903) 78.4
Amer. Med. Miss. Coll., Chicago	(1903) 77.1
Royal College, Surgeons, England	(1895) 85.3
McGill University	(1899) 80.6
Jefferson Medical College	(1901) 81.1
Medical College of Ohio	(1880) 85.2
Johns Hopkins University	(1902) 78.5
Bellevue Hospital Medical College	(1869) 75.7
Albany Medical College	(1887) 81.5

FAILED.

American Medical Missionary College	(1902)	70.2
Long Island Hosp. Med. Coll., New York	(1899)	64.0
University of South Tennessee	(1901)	73.4

PRACTICE OF MEDICINE.

(The three sets are the regular, homeopathic and eclectic, and the applicant may answer one set.)

1. Symptoms and treatment of typhoid fever. 2. What is the difference between intermittent and remittent fever? 3. Symptoms and treatment of scarlet fever. 4. Symptoms and treatment of measles. 5. Symptoms and treatment of erysipelas. 6. Diagnosis and treatment of variola. 7. Causes and diagnosis of gastric ulcer. 8. Treatment of tapeworm. 9. Diagnosis and treatment of acute Bright's disease. 10. Causes and treatment of cystitis.

1. Diagnose and treat a case of scarlet fever, giving indications for each drug. 2. What is lumbago? Suggest treatment. 3. Differentiate a pneumonia from pulmonary congestion. 4. Give treatment of erysipelas of face. 5. Give three causes of constipation, and give treatment for each. 6. What is chorea? Give your method of treatment. 7. Describe a case of gastric ulcer. 8. How would you treat a case of cystitis? 9. Patient restless, high temperature following defined chill, skin dry, severe muscular aching, coryza, headache. Give diagnosis and treatment. 10. Give symptoms and treatment of spasmodic croup.

1. What are the lesions commonly found, or that may occur in the natural (clinical) history of diabetes mellitus? Give the treatment of diabetes mellitus. 2. *Give the etiology of biliary calculi.* Describe the symptoms and the treatment of obstruction of the ductus communis. 3. Give a motor, a sensory and an optical symptom of tabes dorsalis. Locate the essential lesion. 4. Describe the symptoms of any one disease of the pancreas. 5. Enumerate and describe the common types of malarial intermittent fever. Give the etiology and the treatment. 6. Give the differential diagnosis of intussusception of small intestine and acute appendicitis. 7. Give the physical signs of moderate effusion in the left pleural cavity. 8. What are the more *frequent causes of* endocarditis? Describe the physical signs of a mitral insufficiency. 9. Give the physical signs and describe the symptoms that would lead to the diagnosis of tuberculosis of the lungs at an early stage (the period of invasion). 10. Describe the blood changes in anemia (secondary) and pernicious anemia (primary).

CHEMISTRY AND TOXICOLOGY.

(Answer any 10 and only 10.)

1. Describe a method of preparing oxygen. 2. Define the terms distillation, sublimation; give examples of each. 3. Mention five elementary substances commonly used in medicine in an uncombined state. 4. State two laws governing chemical combinations. 5. Explain the nomenclature *of binary* compounds. 6. Describe a galvanic cell; explain the chemical changes occurring during action. 7. What is a compound radical? Give two examples. 8. Give the chemical names for (1) tartar emetic, (2) cream of tartar, (3) Glauber's salts, (4) copperas, (5) sugar of lead. 9. What is chloroform? How is it made? 10. What is glycerin? How is it classified chemically? 11. Give two tests for morphin. 12. What is the antidote for arsenic poisoning? Why? 13. What the antidote for poisoning by lead acetate? Why? 14. Describe in detail a test for sugar in urine. 15. What is the normal reaction of fresh urine? Explain the effect of decomposition on this reaction.

MATERIA MEDICA (HOMEOPATHIC).

1. What symptoms determine choice of aconite in any form of acute disease? 2. Differentiate the cough symptoms of *belladonna*, sticta and ipecac. 3. Give an outline of the action of opium. 4. Differentiate apis and rhus in the treatment of erysipelas. 5. Give three characteristic symptoms of lachesis and what is the character of its hemorrhage? 6. Give the indication for bryonia, *and colchicum* in rheumatism. 7. Give the action of ergot on the spinal cord. 8. Differentiate iris, glonoin and gelsemium in headache. 9. Give guiding symptoms of sepia and helonias in female diseases. 10. Give the bowel symptoms of merc. corr.

PATHOLOGY.

1. Discuss immunity, giving special attention to acquired immunity, to toxin immunity, and to the theories of the nature of immunity. 2. Under what conditions *occur a physiologic* leukocytosis? Under what pathologic conditions would you expect to find a polymorphonuclear leukocytosis? A lymphocytosis? 3. Name three processes marked by retrogressive changes in tissues. Three marked by progressive changes. 4. Illustrate by a drawing the *microscopic* structure of an adenoma, an adenocarcinoma and a lymphosarcoma. 5. What is the significance of hyaline casts in urine? Of granular casts? 6. Name two sequelæ of asthma and tell how they are brought about. 7. Give the pathology of embolus. Of thrombus. 8. What *macroscopic pathologic conditions* would you expect to be able to demonstrate in a subject where death was due to parenchymatous nephritis and its complications? 9. Examination of pathologic specimens. 10. Examination of *x*-ray plates.

MATERIA MEDICA AND THERAPEUTICS.

1. Name five drugs which by their action on the vasomotor centers dilate peripheral blood vessels. Five that contract. 2. Explain the action of counterirritants, and give three that are *safe to apply* over large areas. 3. Give source, preparations with doses and therapeutics of salicylic acid. 4. Give action and therapeutics of diphtheria antitoxin. What conditions would cause you to increase or diminish the quantity given in the course of treatment? 5. What is the *physiologic action of arsenic, given in small* doses three times a day? Given in full medical doses three times a day? What per cent of Fowler's solution is arsenious acid? 6. Compare the physiologic action of tannic acid with gallic acid. 7. Give two formulæ for preparing nutriment for rectal feeding. 8. Write a prescription containing two drugs beside the vehicle, for acute bronchitis, marked by a dry harassing cough. Use no abbreviations. 9. Give the physiologic action of amyl nitris, and name three drugs that are largely antagonistic to this action. 10. *What would you consider a safe initial adult dose of* sulphate of strychnia, sulphate of morphia, chloral hydrate, sulphate of hyoscyamin and the hydrochlorate of pilocarpin?

MATERIA MEDICA (ECLECTIC).

1. Name three heart tonics. 2. What are the medical properties of ammonium carbonate. 3. What are tinctures, infusions and decoctions. 4. What is meant by the term hydragogue? 5. Give the therapeutic properties of podophyllin. 6. In prescribing iron what *form do you prefer, and why?* 7. What *precautions are necessary* in prescribing strychnia, opium and lobelia? 8. Define narcotics, laxatives, antispasmodics, giving example of each. Give specific indications for gelsemium, belladonna, apis. 10. Give medical properties of digitalis with principal organs influenced.

SURGERY.

1. Describe the lymphatic involvement in an advanced case of carcinoma of the stomach, and state the significance of such from the standpoint *of operative treatment.* 2. *Describe in detail* the technic of saline intravenous injections. 3. Describe and give treatment of glaucoma. 4. Differential diagnosis and treatment of varicocele. 5. Describe *in detail* the methods of service in combating complications occurring during chloroform anesthesia. What is Laborde's method of producing artificial respiration? 6. Name varieties and give treatment of goiter. 7. Describe in detail Schleich's method of local anesthesia. 8. Define the following terms: Enteroplosis, pyelophlebitis, cholecystogastroenterostomy, ment of glaucoma. 4. *Differential* diagnosis and treatment of foreign bodies of the bladder in the male and female. 10. Differential diagnosis and treatment of cancer of the rectum.

OBSTETRICS.

1. What is vicarious menstruation? What is the menopause, and what symptoms herald its approach? 2. Define extrauterine pregnancy. Give the symptoms, differential diagnosis, classification and management of the same. 3. Give the natural causes, symptoms and the management *of a case of abortion* during the early months of pregnancy. 4. What is "quickening," and at what period of pregnancy is it usually noticed? Describe fetal heart sounds, their rate, when and where are they best heard? 5. What are the causes of rupture of the uterus in labor? Give the signs, symptoms, prognosis and management of both mother and child. 6. What is version? Give the varieties, application and technic of each. 7. Give the stages of labor and describe what takes place during each stage. 8. What is the best method of delivering the placenta? 9. What are the *principal congenital defects* of the new-born child. 10. What is phlegmasia alba dolens? Give symptoms, treatment and results.

BACTERIOLOGY.

1. Describe *the bacteriologic methods of service* in the clinical diagnosis of typhoid fever. 2. With what micro-organisms may Koch's bacillus be confounded? 3. Describe the bacteriologic diagnosis of diphtheria, and state the action of the diphtheria bacillus. 4. *Define the following terms:* Hemolysis, chemiotaxis, obligatory aerobes and facultative anaerobes. 5. Describe Metchnikoff's theory of immunity, and state its value as an explanation of the facts of immunity. 6. Name three chromogenic bacteria. 7. Describe briefly the principles of the Pasteur treatment of rabies. 8. Describe *method of examining pus.* 9. Examination of cultures. 10. Examination of smears.

ANATOMY.

(Answer any 10 questions, but no more.)

1. What is the foramen *magnum, and what does it transmit?* 2. Describe the mastoid portion of the temporal bone, giving its surgical importance. 3. Give number and name of the various regions of the skull. 4. Bound the pelvic cavity and name the contents. 5. How is collateral circulation established after ligation of the common carotid? 6. In what do the pulmonary veins differ from others? 7. What composes the portal system of veins?

8. Name the divisions of the brain. 9. Give the gross anatomy of the liver. 10. Describe the hip joint and name the ligaments. 11. Describe the pericardium as a structure, and give the blood and nerve supply. 12. What is the pleura? Give its reflections. 13. Name the biliary ducts and briefly describe each. 14. What is the pharynx, and what openings communicate with it? 15. What is the popliteal space, and what does it contain?

PHYSIOLOGY.

1. What are the causes of the first and second sounds of the heart? 2. Describe the difference in function of the afferent and efferent nerves. 3. Define the digestive process. 4. What is meant by tidal, complemental, reserve and residual air? 5. How do the products of digestion find their way into the venous blood? 6. What is the origin and use of glycogen? 7. What is the function of the ninth cranial nerve? 8. What are the functions of the skin? 9. What is the function of the optic thalami? 10. Where is the location of the center for articulate speech.

The Public Service.

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, for the week ending Feb. 27, 1904:

Girard, Alfred C., asst.-surgeon general, assigned to duty as chief surgeon, Department of California.

Torney, Geo. H., deputy surgeon general, relieved from temporary duty as chief surgeon, Department of California, and assigned to duty in command of U. S. Army General Hospital, Presidio of San Francisco.

Kendall, Wm. P., surgeon, relieved from duty at U. S. Army General Hospital, *Presidio of San Francisco*, and ordered to Ord Barracks, Cal., for duty.

Waterhouse, Samuel M., asst.-surgeon, relieved from duty on the transport *Logan* and from further duty in the Philippine Division, and ordered to Fort Worden, Wash., for duty.

Patton, Irvine W., asst.-surgeon, relieved from further duty at Fort Hamilton, N. Y., and is assigned to duty as surgeon on transport *McClellan*.

Waterhouse, Samuel M., asst.-surgeon, granted two months' leave of absence.

Vaughan, Milton, contract surgeon, arrived on the *Logan*, at San Francisco, February 12, for treatment.

Wells, Francis M., contract surgeon, arrived on the *Logan* at San Francisco February 12, on two months' leave of absence from the Division of the Philippines. This leave he availed himself of February 25, after accompanying troops to Columbus Barracks, Ohio.

Wythe, Stephen, contract surgeon, relieved from duty February 18, at the Presidio of San Francisco, and assigned to duty as transport surgeon of the *Buford*.

Foster, Douglas E., contract dental surgeon, left Madison Barracks, N. Y., February 24 for his proper station, Fort Hancock, N. J.

Chambers, Wm. H., contract dental surgeon, arrived February 19, at Atlanta, Ga., for duty in the Department of the Gulf.

Hughes, Leonard S., contract surgeon, on leave of absence from the Division of the Philippines; extension of one month granted.

Jordan, Edward H., contract surgeon, on leave of absence from the Division of the Philippines; extension of one month granted.

Navy Changes.

No changes in the medical corps of the Navy for week ending Feb. 27, 1904.

Marine-Hospital Service.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service, for the seven days ended Feb. 25, 1904:

Stoner, G. W., surgeon, four days' leave of absence from Feb. 24, 1904, under Paragraph 189 of the Regulations.

Anderson, J. F., P. A. surgeon, granted leave of absence for two days from February 18, on account of sickness.

Stansfield, H. A., and McClintic, T. B., asst.-surgeons, to report to chairman of examining board at Washington, D. C., March 9, 1904, for examination to determine their fitness for promotion to the grade of P. A. surgeon.

Berry, T. D., assistant surgeon, directed to *rejoin station* at Louisville, Ky., on the return of Surgeon G. M. Guiteras.

Herty, F. J., pharmacist, granted leave of absence for four days from Feb. 14, 1904, under Paragraph 191 of the Regulations.

PROMOTIONS.

Geddings, H. D., P. A. surgeon, commissioned as surgeon, to rank as such from Nov. 23, 1903.

Wertenbaker, C. P., P. A. surgeon, commissioned as surgeon Feb. 16, 1904.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine Hospital-Service, during the week ended Feb. 26, 1904:

SMALLPOX—UNITED STATES.

California: San Francisco, Feb. 7-14, 5 cases.
District of Columbia: Washington, Feb. 13-20, 6 cases.
Florida: Jacksonville, Feb. 13-20, 5 cases.
Georgia: Liberty County, Feb. 12, 7 deaths.
Illinois: Danville, Feb. 13-20, 3 cases.
Louisiana: New Orleans, Feb. 13-20, 1 case imported.
Maine: Calais, Feb. 18, 5 cases.
Maryland: Baltimore, Feb. 13-20, 1 case.
Michigan: Detroit, Feb. 13-20, 2 cases, 1 death.
Missouri: St. Louis, Feb. 13-20, 5 cases.
New Hampshire: Manchester, Feb. 13-20, 1 case.
New Jersey: Trenton, Feb. 13-20, 7 cases.
New York: Feb. 13-20, New York, 3 cases, 1 death; Niagara Falls, 5 cases.
Ohio: Cleveland, Feb. 12-19, 1 case.
Pennsylvania, Feb. 6-13, Butler, 1 case; Williamsport, 1 case; Carbondale, Feb. 14-21, 1 case; Feb. 13-20, Johnstown, 4 cases; Philadelphia, 49 cases, 13 deaths; Pittsburg, 2 cases, 1 death; *Titusville, 1 case.*
Tennessee: Feb. 13-20, Memphis, 31 cases; Nashville, 7 cases.
Utah: Salt Lake City, Feb. 6-13, 1 case.
Virginia: Danville, Feb. 6-13, 2 cases.
Wisconsin: Milwaukee, Feb. 13-20, 11 cases.

SMALLPOX—INSULAR.

Hawaii: Honolulu, Feb. 4, 1 case on U. S. T. *Logan*.

SMALLPOX—FOREIGN.

Austria: Prague, Jan. 23-30, 3 cases.
Brazil: Pernambuco, Jan. 1-15, 39 deaths; Rio de Janeiro, Jan. 17-24, 24 cases, 27 deaths.
Canada: Quebec, Feb. 6-13, 1 case; Tower Hill, N. B., Feb. 15, 2 cases.
Colombia: Barranquilla, Jan. 27-Feb. 2, 5 deaths.
France: Marseilles, Jan. 1-31, 29 deaths; Paris, Jan. 30-Feb. 6, 31 cases, 2 deaths.
Great Britain: Jan. 30-Feb. 6, Edinburgh, 17 cases, 1 death; Hull, 3 cases; Manchester, 3 cases; Newcastle-on-Tyne, 2 cases, 1 death; Nottingham, 11 cases; South Shields, 1 case; Sunderland, 1 case; Glasgow, Feb. 5-12, 46 cases, 2 deaths; London, Jan. 23-30, 4 cases; Sheffield, Jan. 23-Feb. 6, 3 cases.
India: Bombay, Jan. 19-26, 7 deaths; Karachi, Jan. 17-24, 2 cases, 1 death.
Mexico: City of Mexico, Jan. 31-Feb. 7, 4 cases, 3 deaths.
Netherlands: Amsterdam, Jan. 30-Feb. 6, 3 cases.
Russia: Moscow, Jan. 16-23, 5 cases, 4 deaths; St. Petersburg, Jan. 23-30, 11 cases, 8 deaths.
Spain: Santander, Feb. 1-8, 5 cases.
Turkey: Smyrna, Jan. 17-31, 5 deaths.

YELLOW FEVER.

Brazil: Rio de Janeiro, Jan. 17-24, 3 cases, 1 death.
Cuba: On Nor. bk. Eugen from LaGuaira, Mez., wrecked on South coast Feb. 16, 7 cases, 5 deaths.
Mexico: Jan. 31-Feb. 13, Merida, 1 case, 4 deaths; Progreso, 1 case; Vera Cruz, Feb. 6-13, 1 case, 1 death.

CHOLERA—INSULAR.

Philippine Islands: Manila, Jan. 2-9, 4 cases, 4 deaths.

CHOLERA—FOREIGN.

India: Calcutta, Jan. 8-23, 38 deaths.
Turkey in Asia: Diarbekir, Jan. 9, 1 death; Kerbela, Jan. 11-12, 5 cases, 5 deaths.

PLAGUE—UNITED STATES.

California: San Francisco, Feb. 12-14, 2 deaths.

PLAGUE—FOREIGN.

Brazil: Pernambuco, Jan. 1-15, 1 *death*; Rio de Janeiro, Jan. 17-24, 8 cases, 6 deaths.
India: Bombay, Jan. 19-26, 231 deaths; Calcutta, Jan. 8-23, 23 deaths; Karachi, Jan. 17-24, 8 cases, 7 deaths; Madras, Jan. 16-22, 1 death.
Peru: San Pedro, Feb. 20, *a* few cases.
Russia: Cronstadt, Jan. 20, 1 death, laboratory case.

Medical Organization.

Iowa.

Lucas County Medical Society.—Physicians of the county met at Chariton, February 13, and with the aid of Dr. David C. Brockman, Ottumwa, councilor for the Sixth District, organized a county society on the standard plan, adopted the constitution and by-laws recommended by the state society, and elected the following officers: President, Dr. Albert L. Yocum, Chariton; vice-president, Dr. David Q. Storie, Jr., Chariton; secretary-treasurer, Dr. John H. Stanton, Chariton; delegate to state society, Dr. Herbert H. Nelson, Russell, and committee on public health and legislation, Drs. John H. Stanton, Edgar L. Field and David Q. Storie, Jr., all of Chariton.

Kentucky.

Seventh Councilor District.—Dr. James G. Carpenter, Stamford, councilor for this district, reports that he has organized eleven of the twelve counties which constitute his district.

North Dakota.

Sixth Judicial District Medical Society.—The physicians of this district have organized with the following officers: President, Dr. Francis R. Smyth, Bismarck; vice-president, Dr. George E. Chamberlain, Bismarck, and secretary and treasurer, Dr. Frederick B. Strauss, Glen Ullin.

Texas.

Red River County Medical Society.—Twenty physicians of the county met at Clarksville, February 15, and organized a county society with the following officers: Dr. John C. Foster, Clarksville, president; Dr. James C. Durrum, Clarksville, vice-president; Dr. W. Newlin Watson, Clarksville, secretary and treasurer, and Drs. Henry R. Smith, Detroit, Charles T. Clark, Clarksville, and M. C. McNew, censors.

Marion County Medical Society.—Pursuant to a call issued by Dr. Holman Taylor, councilor of the Fifteenth (Northeast) District, physicians of the county met at Jefferson and organized a medical society with an initial membership of 7, and the following officers: Dr. John A. R. Moseley, president; Dr. Robert L. Armistead, vice-president; Dr. Rogers Cocke, secretary and treasurer, and Drs. Robert A. Sterrett, Albert G. Clopton, and Archibald A. Terhune, censors, all of Jefferson.

Wisconsin.

Grant County Medical Society.—This society, which was reorganized in July last (The Journal, xli, page 384), received its charter from the state society January 4.

Society Proceedings.

NATIONAL LEGISLATIVE COUNCIL.

Meeting held at Washington, D. C., Feb. 11, 1904.

Dr. C. A. L. Reed in the Chair.

The meeting was called to order by Dr. Chas. A. L. Reed, Cincinnati, chairman of the National Legislative Committee of the American Medical Association. The following were present: Dr. Chas. A. L. Reed, Ohio; Dr. J. R. Currens, Wisconsin; Dr. Wm. E. Anderson, Virginia; Drs. J. B. Sanford and S. D. Van Meter, Colorado; Dr. R. E. Conniff, Iowa; Dr. E. J. McKnight, Connecticut; Dr. R. T. Sloan, Missouri; Dr. Henry Beates, Jr., Pennsylvania; Dr. E. E. Harris, New York; Dr. R. A. Marmion, U. S. N.; Dr. James Evans, South Carolina; Dr. J. W. Bovée, District of Columbia; Dr. Walter Wyman, U. S. Public Health and Marine-Hospital Service; Dr. J. T. Wrightson, New Jersey; Surgeon-General O'Reilly, U. S. A.; Dr. Edie, U. S. A.; Dr. W. C. Borden, U. S. A.; Dr. Chas. MacLachlan, New Rockford, S. D.; Dr. W. H. Sanders, Montgomery, Ala.

On motion of Dr. S. D. Van Meter it was voted that this body, consisting of the Committee on Legislation and the State Auxiliary Legislative Committee, be called the National Legislative Council. On motion of Dr. McKnight of Connecticut, Dr. C. A. L. Reed of Ohio, chairman of the Committee on Medical Legislation of the American Medical Association, was elected chairman of the Council.

On motion of Dr. R. E. Conniff of Iowa Dr. J. B. Sanford of Colorado was elected secretary.

Dr. Reed presented a brief summary of the matters to come up at this meeting, after which Surgeon-General Wyman was called on and explained what measures were now asked of Congress by his department.

On motion of Dr. Conniff it was voted that the matter of the Colorado Medical Legislative League be referred to a committee of three. The chairman appointed Drs. Van Meter, Currens and Conniff.

It was voted that the chairman appoint such committees as are needed to investigate and report on such special topics as the chairman had already brought to the attention of the Council. The chairman appointed the following: On Army bills: Drs. Bovée, Borden and Beates. On Navy bills: Drs. McKnight, Marmion and Anderson. On Public Health and Marine-Hospital Service: Drs. Conniff, Evans and Sloan. On antitoxin: Drs. Harris, Wyman and Welch. On state organization: Drs. Van Meter, Currens and Conniff.

The following committee was appointed to consider the matter of a department of public health in the National government: Drs. Wrightson, Harris, Sloan, MacLachlan and Anderson.

It was moved by Dr. Van Meter of Colorado to go into committee of the whole on the question of uniform state medical legislation, at such hour as the chairman might designate. Motion carried. The chairman appointed 4 o'clock p. m. as the hour.

It was moved by Dr. Harris that Dr. Wiley, chief of the Bureau of Chemistry, Department of Agriculture, be invited to address the body in the afternoon on proposed legislation relating to drugs and pure foods. Carried.

Dr. S. D. Van Meter of Colorado presented a proposed amendment to state laws to require a bond of indemnity from plaintiffs in action for damages, and moved that a committee be appointed to report at the afternoon session. Carried. Chair appointed Drs. Van Meter, Sloan and Currens.

At the afternoon session an invitation was received through Hon. Francis B. Loomis, First Assistant Secretary of State, to visit the President at 1 o'clock to-morrow; this was accepted with a vote of thanks to Mr. Loomis.

The committee on bills relating to the Public Health and Marine-Hospital Service reported as follows:

Whereas, The Secretary of the Treasury has submitted to Congress an estimate for an appropriation of $75,000 for the Hygienic Laboratory of the Public Health and Marine-Hospital Service, providing for a building and grounds. This laboratory was established by Congress in 1900 for the investigation of infectious and contagious diseases and matters pertaining to the public health. Thirty-five thousand dollars was appropriated for buildings which have been erected. In 1902 the scope of the laboratory was largely extended to the addition of three new divisions, viz.: the diseases of medical zoology, pharmacology and chemistry. To accommodate these a new building is necessary. The importance of this institution is further illustrated by the provision of law requiring an advisory board, consisting of the director, representatives of the Medical Department of the Army and Navy and of the Bureau of Animal Industry of the Department of Agriculture and five members in the regular employ of the government, but skilled in laboratory work in its relation to public health.

Wherefore, Your committee would urge on the American Medical Association the necessity of encouraging in every possible way the development of the Hygienic Laboratory on the broad lines laid down by Congress, and should urge that body to act favorably on the recommendations of the Secretary of the Treasury for the much-needed accommodations for the additional work imposed on it by Congress itself. Respectfully submitted.

R. E. Conniff.
R. T. Sloan.
James Evans.

The committee on legislation relating to the Navy reported:

Your committee has had under consideration the several bills referred to it, namely: "A Bill Authorizing the Establishment and Organization of a Corps of Dentists in the U. S. Navy," "A Bill for the Establishment and Organization of a Nurse Corps of Trained Women Nurses in the U. S. Navy," and "An Act to Reorganize and Increase the Efficiency of the Hospital Corps of the Navy of the U. S., to Define Its Duties and Regulate Its Pay," and that it finds that these measures have all received the approval of the Secretary of the Navy and of the Surgeon-General of the Navy and are now in the hands of the Committee on Naval Affairs of the two houses of Congress.

Your committee also reports that it unanimously approves the provisions of these measures and recommends that the National Legislative Council give them their sanction and whatever moral and active support they can through the legislative committee.

Your committee, however, feels that these measures are in such a favorable condition that they do not call for any definite action at this time by this subcommittee. Respectfully submitted,

E. J. McKnight.
R. A. Marmion.
Wm. E. Anderson.

The report was adopted and the committee discharged.

The committee on antitoxin reported as follows:

Resolved, That there should be prepared in the United States a standard antitoxin for determining the strength of antidiphtheric serum and that the Public Health and Marine-Hospital Service be requested to prepare and maintain said standard. Be it further

Resolved, That antidiphtheric serum shall be introduced into the United States Pharmacopeia, and that the standard prepared by the Public Health and Marine-Hospital Service be made officinal.

Resolved, That a copy of this resolution be sent to the Committee on the Revision of the Pharmacopeia. Respectfully submitted,

E. Elliot Harris.
Walter Wyman.

The report was adopted and the committee continued, with instructions to carry the purposes of their report into effect.

The special order on a standard medical act was called at 4 o'clock.

Dr. Van Meter of Colorado moved that a committee of five be appointed by the chairman, with instructions to formulate a standard medical practice act to be presented at an adjourned meeting of this council to be held at Atlantic City on the Monday preceding the regular meeting of the American Medical Association. After discussion, participated in by Drs. Van Meter, Currens, Bovée, Wrightson, Conniff, McKnight, Evans, Harris and Sloan, the motion was adopted. The chairman appointed Drs. Van Meter, Currens, Sanders (Alabama), Amberg (Michigan), Dibrell (Arkansas) as such committee.

The committee on state organization reported as follows:

We, the committee on state organization, report that we recommend the Colorado plan without reservation so far as consistent with local conditions.

We would further recommend that each state proceed to organize along such lines; each organization to contain the feature of convincing the public that medical registration laws are not promulgated for the benefit of the medical profession, but for the good of the people at large. Respectfully submitted,

S. D. Van Meter, Chairman.
J. R. Currens.
R. E. Conniff.

Dr. J. Wesley Bovée of the District of Columbia introduced Dr. Bryant, a dentist, who presented to the Council a bill amending the statutes relating to patents, relieving medical and dental practitioners from unjust burdens imposed by patentees holding patents covering methods and devices for treating human diseases, ailments and disabilities, and who asked the aid of the Council in passing this bill. After discussion by the various members of the Council the matter was referred to a committee of five consisting of Drs. E. J. McKnight, Dr. Henry Beates, Jr., Dr. R. T. Sloan and James Evans, to be determined on later in the day.

The following resolution was offered by Dr. Harris of New York:

Whereas, The well-known insanitary condition prevailing on the Isthmus of Panama, as shown by the large percentage of sickness and death among the laborers engaged in the previous work on the Panama Canal, and in view of the fact that the successful prosecution of future work on the canal must largely depend on the sanitary administration, which includes the prevention of sickness and the saving of the lives of the laborers, quite as much as on the solution of the great engineering problem;

Resolved, That a representative of the medical profession who is an authority on the advanced methods of investigating the causes and of the prevention of disease, should be appointed a member of the canal commission, that he may have authority to protect the health and thereby save the lives of persons engaged to work on the proposed Panama Canal.

The resolution was adopted, and on motion the chairman, Dr. Reed, was authorized to use it as he saw fit.

Dr. H. W. Wiley, chief of the Bureau of Chemistry, Department of Agriculture, was next introduced, and addressed the Council on the subject of the pure food bill now pending in the Senate.

At the evening session Dr. J. W. Bovée presented the report of the committee on Army medical bills. (See The Journal A. M. A., pages 605 to 607, Feb. 27, 1904.)

The report of committee on a bill relating to patents to relieve medical and dental practitioners from unjust burdens imposed by patentees, etc., reported that as the bill does not directly affect the medical profession it was not within the jurisdiction of the committee to take action thereon. The report was accepted and the committee discharged.

On the roll call of states reports on the condition of medical legislation were presented as follows: Dr. S. D. Van Meter, for Colorado; Dr. E. J. McKnight, Connecticut; Dr. J. W. Bovée, District of Columbia; Dr. R. T. Sloan, Missouri; Dr. L. E. Harris, New York; Dr. Henry Beates, Pennsylvania; Dr. James Evans, South Carolina; Dr. Currens, Wisconsin; Dr. Chas. MacLachlan, South Dakota.

On motion the chairman at his discretion was requested to make a referendum on each of the following questions:

First: Appointment of a medical representative on the Panama Canal Commission.

Second: On the Army medical bills.

Third: On the pure food and drug bills.

On motion the Council adjourned to meet at Atlantic City June 6, 1904.

CLEVELAND ACADEMY OF MEDICINE.

Regular Meeting of the Section of Experimental Medicine, held January 22, 1904.

Dr. William H. Weir, vice-president of the Section, in the Chair.

The Effects of the Simultaneous Action of Pilocarpin and Atropin on the Development of the Embryo of the Starfish and Sea-urchin.

The experiments embodied in this paper by Dr. Torald Sollmann were a sequence to the work of A. P. Mathews, who has observed that pilocarpin stimulates the development of the embryos of asterias and arbacia, while atropin depresses it. This affords an opportunity of studying the result of the combined action of two poisons having opposite effects on the same cell, and presumably on the same structure. The method consists simply in placing the fertilized ova in salt water containing varying concentrations of the two alkaloids, and comparing the development at daily intervals for about a week. Seven experiments were made in all. Consideration of the results obtained led to the following conclusions:

Atropin alone is absolutely devoid of stimulant action, the smallest effective doses being depressant. Pilocarpin stimulates in small doses and depresses in larger doses. If the action is prolonged, the depressant phase predominates more and more.

When the solutions contain both poisons; it is found that atropin prevents the stimulating action of pilocarpin completely, and this effect appears even with doses of atropin which seem entirely inactive when used alone.

Small stimulant doses of pilocarpin lessen the depressant action of moderate doses of atropin, but in no cases do they remove the depression entirely. Larger stimulant, and all depressant doses of pilocarpin increase the atropin depression. This shows that both drugs are acting on the cell, even when they mutually obscure their action, and also shows that small doses of a stimulant are more efficient than large doses in removing a depression, providing that both poisons act on the same cell.

An Experimental Research Into the Cause of Death from Electric Shock.

This paper by Drs. G. W. Crile and J. J. R. Macleod gave an account of the effect of industrial electric currents on anesthetized dogs. With alternating currents (as used for lighting purposes), results in general confirmatory of those of Prevost and Batelli were obtained, the main points of practical interest in the present inquiry being the variable susceptibility of the dogs to electricity, and the fact that death was invariably caused by fibrillary twitching of the heart.

The variable susceptibility was very evident with a voltage of 2,300 volts, some dogs being killed by a momentary application, while others were able to withstand the current for several seconds, in fact, in some cases, as long as the current could be kept on without burning the tissues. The electrodes were in all cases applied similarly, one to the back of the head after the skin had been moistened, or in the mouth, the other to the hind legs or in the rectum. Records of the mean arterial blood pressure were obtained during the experiment, the curves showing a momentary rise of small amount, due to contractions of the muscles, followed by a fall to the abscissa. This fall was found to be due in the first instance to vagus inhibition, and in some dogs this was the only effect of the current, for it was found that in these it could be prevented by the preliminary administration of atropin. These were the dogs which recovered. In other dogs, however, the fall of blood pressure persisted, even after the current was broken, and on opening the thorax the heart was found to be in a condition of fibrillary twitching. Several methods were tried with the hope of restoring the normal heart beat, but with no avail. Perfusion of the coronary arteries with Locke's fluid, or with defibrinated blood, massage of the heart, administration of atropin, vagus stimulation and the application of the anode of a constant current were found to have no effect on such a heart. Experiments were then tried in which the electrodes were applied so that none of the current passed through the heart; for example, to the back of the head and to the front of the neck, to the two anterior extremities or to the two posterior extremities. The current in none of these cases produced any other effect than a vagus inhibition, which could be prevented by the use of atropin or by vagus section, and a cessation of respiratory movements, together with tonic convulsions. All these effects passed off when the current was broken, except in some instances, the cessation of the respiratory movements, but these movements could be recovered by the use of artificial respiration. Some of these latter dogs were allowed to come out from under the anesthetic, and were found to be in every way normal. Even 2,300 volts had no visible permanent effects on the respiratory and other centers. In one dog where a current of 2,300 volts was passed between the front legs, fibrillary twitching appeared, probably on account of the spread of the current to the heart. The variable results recorded in the first series of experiments were undoubtedly due to a variable amount of electricity having traversed the heart. By applying the electrodes direct to the heart it was found that fibrillary twitching was produced by the lowest current at disposal (1 volt).

These results suggested that it might be possible to diminish the danger of high electrical currents, by applying to the body well above and below the region of the heart two copper bands, connected by copper wire. In this way a large portion of the current would be taken up by the copper bands and would therefore be excluded from the heart. Several experiments with such an arrangement gave very encouraging results, and the application of the measure is at present being worked out as a prophylactic measure.

With constant currents, 660 volts as used for electric street cars, make and break were alone found to have any action. At both, vagus inhibition, followed by fibrillary twitching of the heart, and death resulted.

NORFOLK DISTRICT MEDICAL SOCIETY.

Meeting held at Jamaica Plain, Mass., Feb. 23, 1904.

The President, Dr. Walter Channing, in the Chair.

The New Harvard Medical School.

Dr. **Harold C. Ernst**, professor of bacteriology in Harvard Medical School, illustrated this subject by stereopticon views. This was the first full explanation of the plans which has been given to the medical profession.

Much time was spent in the choice of a location, and finally a piece of land containing 26 acres was purchased. It is an irregular square, bounded on two sides by Francis Street and Huntington Avenue and faces the end of Tremont Street. Not all this land is to be occupied by the school. On one corner will be the Brigham Hospital, while in other portions will be located the Good Samaritan Hospital, the Children's Hospital and the Infants' Hospital. Almost adjoining is the new Deaconess' Hospital, and but a few minutes' walk the Baptist Hospital, and the Woman's Charity Club Hospital on Parker Hill, overlooking this location.

The medical school itself will face on Longwood Avenue. Plans are already far advanced for the city of Boston to build a new entrance to its beautiful Fenway Park, passing out between the Venetian Palace of Mrs. John L. Gardner and the new Simmons College and ending just in front of the court of the medical school. This court will be rather more than 400 feet deep from the street. At the back will appear the administration building and on either side two laboratory buildings. These will be on one side, in front, for pathology and bacteriology, and about 50 feet back of that anatomy, histology and embryology. On the other side of the court, in front, hygiene and pharmacology, and back physiology and physiologic chemistry. The buildings are to be of white marble with practically no wood in their construction, and will present a most imposing architectural appearance to any such approach from the parkway.

The group of five detached buildings is the result of very much study and gradual development of ideas. The leaders in all this work have been Drs. Henry P. Bowditch and John C. Warren. Land and buildings are to cost $2,500,000. The purpose has been to relieve the present pressure on students and professors and to establish a great center for medical education and research.

The four laboratory buildings are in general very similar in construction. Each has a front on the court of 180 feet, 74 feet of this being in the center and 53 feet, on each side of this central portion, being the front of two wings running back from the court. There are three floors. In the central portion is an amphitheater to seat 342 students. The professor enters this from his own special rooms on the lower floor, which, on the level with the ground, is styled the basement. Students enter on the first floor. Here, beside the entrance for them to the amphitheater, is the department library, over the professor's rooms and in front of the amphitheater. This last is lighted in each case by overhead windows. The wings constitute the laboratories. One subject is to be taught in each wing and allied subjects are to be in the wings of each building as indicated above. This is in accordance with Harvard's new system of "extensive" instruction. A student will, therefore, spend his mornings in one wing of a building and his afternoons in the other wing, only leaving his laboratory to pass into the amphitheater for a lecture, and not leaving the building at all, unless for lunch. Lockers for the students are provided along the hallways. Plans are made to care for a class of 200, not including special research students. The laboratories are on the unit system, each being planned to accommodate 20 students, and hence allowing of indefinite expansion by building on at the ends of the wings. Students are grouped on the first floor and research workers on the second floor. The basement has a height of 12 feet and the other two stories of 18 feet each. There is also a further space above each building which is not evident from the outside, and which will be largely used for the animals needed in each of the departments.

The building for pathology and bacteriology has some peculiarities in its internal arrangements. There are large laboratories for the students instead of the unit laboratories, and the students are put in one wing, one laboratory being superimposed on the other. In the other wing are the smaller rooms for research workers, and two extra floors have been introduced giving rooms only 9 feet high. The library in this building, which is to be known as the Huntington Building, is larger, being 35x70 feet. The animals are to be kept in a building to be built back of the amphitheater between the wings. Externally the four buildings will be much alike, the two on either side of the court being separated by a space of almost 50 feet.

The administration building, at the back of the court, will be considerably more elaborate architecturally. It and the two buildings nearest it are the gift of J. P. Morgan. It will be occupied by offices on the first floor, a lecture room seating 340, and the Warren Museum on the second and third floors. The basement, which in this case, too, is level with the ground, will be devoted to the uses of students, lunch, lounging, library, reading rooms, etc.

The faculty have already established a students' health committee and a students' aid committee, whose functions will be much enlarged in the new buildings. A dormitory is much desired. Instruction in the new school will include, beside the present courses, such advanced work in medicine as shall enable a man to earn a Ph.D. or Sc.D.

Harvard's entrance standard, A.B., or its equivalent, has cut her enrollment from 750 to a little over 400. The numbers are again increasing, however. For the maintenance of this plant there are $1,500,000 funds available. Much more is needed. The per capita expense throughout the university gives the student $275 worth of instruction for the $200 he pays for tuition.

NEW YORK ACADEMY OF MEDICINE.

Meeting held Feb. 18, 1904.

The President, Andrew H. Smith, M.D., in the Chair.

The Hospital Car—Its Equipment, Uses and Importance.

Dr. **Wm. W. Sanford** presented drawings and gave a description of such a car and pleaded that many should be introduced on the various railway systems and placed at certain intervals ready at all times to answer calls at times of accidents.

Dr. **Andrew H. Smith** believed that if the companies would look to the needs of the injured more and have such cars the verdicts of juries would be less often against them than is the case at present.

The Rationale of the Natural Arrest of Consumption.

Dr. **W. B. McLaughlin**, Austin, Texas, considered the effect of sea voyages, outdoor life, etc., on the disease, and made suggestions as to ideal treatment. The study of the forces employed by Nature in dealing with the tubercle resolves itself naturally into the study of the pure tuberculosis infection and the study of complicating infections. Nature walls off pure tuberculosis infections with connective tissue, the rapidity of the process being in proportion to the vascularity of the part. In chronic ulcerative phthisis the mischief and ultimate death of the patient is largely caused by the complicating infections, the micro-organisms of which, if left to themselves and not reinforced by new infections, would become attenuated and finally die out. Experiments with dogs show this. It seemed to him that the deduction was inevitable, that if a patient suffering from chronic ulcerative phthisis was kept in sterile air and his person kept as near aseptic as possible for a sufficient length of time, he must in obedience to the laws of healing recover from his lesion, so far as his ulcerative phthisis was concerned, i. e., his ulcerative phthisis would be converted into a pure tuberculosis, or what was known as a latent tuberculosis. He said that autopsies taught that only 40 per cent. of these cases of latent tuberculosis became active. Thus it could be logically expected that out of every ten patients treated six would remain well, and four become reinfected and be compelled to return for another period of treatment. Many cases of ulcerative phthisis are converted into cases of pure tuberculosis by modern methods of treatment, but the results can not be obtained with mathematical accuracy until we place our patients where reinfection is a practical impossibility.

DISCUSSION.

Dr. George L. Peabody said that the author's purpose might be accomplished in the deserts of Egypt, where sterilized air might be had, or in mid-ocean, but how such air could be supplied artificially he could not see.

Dr. John B. Huber agreed that the tubercle bacillus was not particularly dangerous *per se*, the danger was in mixed infection. The prevention, therefore, of the mixed infection should be the great object.

Col. W. C. Gorgas did not see how such a room could be fixed up and kept aseptic as had been tried in surgical cases. He believed that a very near approach to what was sought for was to be had in a plentiful supply of fresh air. Patients taken into municipal sanatoria and treated in this way, he believed, would get well in three or four months, instead of in from eight to ten months, as at present; this would be a great saving to cities.

Dr. S. A. Knopf emphasized the importance of plenty of fresh air, sunlight, the abolishing of dark rooms with their foul air and filth. In dealing with the tuberculosis problem, he said we should seek after the ideal and do away with things that were not practical. To render and keep the atmosphere of a room aseptic was impossible, but much could be done by teaching the masses to love fresh air; this was practical.

Dr. McLaughlin said that if such a thing as he suggested could be done it would be a great advance in the therapeutics of tuberculosis. So far as the sterilizing of the air was concerned much could be done by the removal of the dust.

Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Melancholia.

In outlining his treatment of melancholia, Aiken, in *West. Med. Rev.*, states that whatever exceptions may be granted members of the family or relatives to act as nurses, they should never be the constant attendants on a case of melancholia. The patient's reasoning power is not diminished, but perverted, and the presence of relatives intensifies the mental pain and deepens the sense of unworthiness which is the burden under which the patient is suffering, fearing, as he does, that he will never regain his social or moral standing. The alimentary canal must be cleansed and kept evacuated, preferably by salines, and the patient must be given nourishment. Milk, eggs, meat juices, soups and other nourishing and easily assimilated food should be administered six to eight times every twenty-four hours. Sleep is best induced by the hot bath, a hot drink, and the administration of trional, sulphonal or such other hypnotics as do not depress the heart. Opium, at least, theoretically so, is contraindicated on account of its tendency to lock up the excretory organs.

The author has had considerable asylum experience and has derived splendid results from the use of tincture of ipecac and opium or pulverized opium in the treatment of melancholia. It moistens the skin, liquefies the alvine discharges and diminishes mental anxiety. The overloaded bowel must be relieved and will sometimes produce sleep when hypnotics fail. In the slow and feeble pulse and when there is vasomotor contraction, the use of belladonna relaxes the arteries, giving a better peripheral circulation. For quieting maniacal outbursts the fluid extract of gelsemium by the mouth or hyoscin hydrobromate subcutaneously and the prolonged use of the hot bath are the best remedies. The nurse must possess an unlimited amount of good nature, even under the most trying circumstances.

Syphilis in Infants.

According to M. Schwab, in *Med. Press*, injections of biniodid of mercury in a watery solution are superior to all other classical methods and the hypodermic treatment should take the place in the treatment of infantile syphilis. It is without danger and is rapid and certain. The average dose should be from one to two milligrams given daily for ten or fifteen days and then suspended for the same length of time, when it should be resumed again for ten days.

The following formula is recommended by the author:

℞. Hydrarg. biniodidi..................gr. 4/5 |05
Sodii iodidi ....gr. 4/5 |05
Aq. destil. ....ʒiiss 10|

M. Sig.: Twenty to thirty drops to be injected into the lumbar region once daily.

Prevention of Iodism.

In an abstract in *Med. Review*, F. Lesser states that it is usually assumed that when potassium iodid is taken into the stomach containing its normal acid secretions, it is broken up and free iodin given off, which produces symptoms of iodism, and to prevent this it has been prescribed with sodium bicarbonate, belladonna or sulphanilic acid. Should it enter the body as free iodin it immediately combines with the albuminous compounds of the body. However, according to the author, with the exception of the thyroid gland no organ contains albuminous compounds of iodin, so that it has never been proven that potassium iodid is not in itself capable of producing iodism, just as iodoform may produce toxic symptoms without decomposition. Iodipin, which is a compound of iodin in sesame oil, is recommended by the writer as a preparation which does not produce iodism if given hypodermically, but has no advantage over potassium iodid if given by the mouth. In whatever way it may be administered, iodipin is excreted as potassium iodid. So he concludes that if either iodipin or potassium iodid be given in small doses and frequently, iodism is not so liable to follow. For instance, instead of giving tablespoonful doses of the mixtures three times a day, a teaspoonful should be given every hour for twelve hours; the total quantity given and therapeutic results are just the same, but iodism is avoided.

Pneumonia.

The use of calomel in pneumonia has been recommended by C. Bertazzoli in *Med. News*. Although he does not consider this preparation as a specific, it should be administered in generous doses, and should be accompanied by such other drugs as provoke energetic peristalsis so as to procure its elimination from the organism rather than be absorbed. He, therefore, administers it combined with scammony because of the latter's effect on the intestine. The calomel produces antipyretic effects and seems to cut short the further spread of the inflammatory process. The headache is also relieved, as well as the delirium. It is also a good diuretic and a reliable disinfectant.

To lower the temperature and pulse in pneumonia, the following combination containing sodium salicylate is recommended:

℞.	Sodii salicylatis	ʒi	4
	Syr. simplicis	ʒiii	12
	Aquæ q. s. ad	℥vi	180

M. Sig.: One tablespoonful every hour until the patient perspires freely.

To relieve the cough and pain in pneumonia Danforth, in *Applied Ther.*, recommends the following combination:

℞.	Codeinæ	gr. ii	12
	Liq. ammon. acetatis		
	Spts. chloroformi, āā	ʒiv	15
	Syr. lactucarii q. s. ad	℥ii	60

M. Sig.: One teaspoonful every hour.

As a substitute for the foregoing prescription the codein may be combined with camphor or ammonium carbonate in order to stimulate the functions of skin.

After the stage of resolution, if cough is troublesome, some expectorant mixture similar to the following is recommended:

℞.	Morph. sulph.	gr. i	06
	Ammon. carb.	ʒi	4
	Aquæ camph.	℥i	30
	Syr. pruni virg.	℥ii	60

M. Sig.: One teaspoonful every three hours.

Typhoid Fever.

In the general management and treatment of typhoid fever at Johns Hopkins Hospital, according to an article in the *Practitioner*, rest, diet and baths comprise the important parts, as no drugs are given unless there be some special indication. Strychnia is given in doses of grain 1/50 each (.0003) every four hours if the pulse becomes rapid and weak. The mouth receives constant care. As a mouth wash the following is recommended:

℞.	Sol. acidi carbol. (1 to 20)		
	Glycerini, āā	℥i	30
	Sol. acidi borici (sat.)	℥viii	240

M. Sig.: To be used as a mouth wash after each feeding.

As to the bowels, a state of constipation is preferred. If necessary, the bowels are moved every second day by a simple enema, preceded sometimes by a large injection of oil. No purgative is given by the mouth during the attack. Diarrhea is taken as a signal for the reduction of the diet, milk being generally cut off. If the diarrhea is not then checked, bismuth is given in full doses or the lead and opium pill is given. In severe cases an enema of laudanum and starch is administered. For the tympanites turpentine is used externally, by the mouth or by enema. The long rectal tube, sometimes inserted and allowed to remain for half an hour, may be of advantage. Alcohol is not given as a routine with the baths. However, if there be a severe toxemia or a failing circulation, it is given freely, because the patient's condition demands it and not because he is getting the baths.

None of the so-called intestinal antiseptics is given. If the heart becomes rapid, pulse weak, and first sound indefinite strychnia in doses of grain 1/60 to 1/20 (.001-.003) is given every four hours with fine results; but it is not given continuously for twenty-four hours.

For the severe headache small doses of bromid or codein or opium are sometimes given, if application of the ice bag is not sufficient.

To prevent severe toxemia baths are of great benefit and if patients can not be induced to take sufficient liquid by the mouth, saline infusions are given regularly three times a day, giving altogether a liter or a liter and a half of fluid. In some cases fluid can be given by the bowel, and if patients refuse to swallow, food is given through the stomach tube. Convalescence is regarded as the most troublesome part of the treatment. The diet should include clear soups, broth, gruel and beef tea when the temperature becomes normal. Junket, custard, jelly and soft-boiled egg may be added after a few days. Soft toast may be added at the end of the first week. From the seventh to the tenth day scraped beef or sweet bread may be added. Iron is given if any grade of anemia is present.

In the treatment of hemorrhage absolute quiet is secured, if necessary, by morphin hypodermically, the diet is reduced to albumin alone or all food discontinued, and it is advisable to discontinue stimulants for a time. A light ice bag is applied to the abdomen. The danger of giving opium by the mouth is in masking the symptoms of a perforation, which so frequently accompanies hemorrhage.

If the blood coagulation time of a patient is longer than normal when entering the hospital, calcium chlorid is given in fifteen-grain doses (1.00) three times a day. Its value as a prophylactic measure has not yet been decided.

Saline infusions should not be given after a hemorrhage unless the patient be in collapse or exsanguine.

Medicolegal.

Construction of Statute as to "Other Agency."—The Supreme Court of New Jersey holds, in the case of State vs. Herring, that an osteopath whose treatment of his patient consists simply of the manipulation of the body, does not violate that provision of the act of May 22, 1894, Section 8, which forbids the applying of "any drug, medicine or other agency or application" by an unlicensed person. It says that the phrase "other agency or application" is a very broad one, and, in its general sense, would undoubtedly include the use of the hands. But it is conjoined to the terms "drug" and "medicine," which are much more special; and, under the maxim, "Noscitur a sociis" (the meaning of a word is or may be known from the accompanying words), its interpretation should be such as will confine it to the class in which its special associates stand. Moreover, as a phrase employed to create and define offenses unknown to the common law, it must be strictly construed. In forbidding an unlicensed person to apply any drug or medicine for remedial purposes, the legislature plainly contemplated the use of something other than the natural faculties of the actor—some extraneous substance. A similar restriction must attach to the more general terms "agency" and "application," and they must likewise be held to import only some extraneous substance.

Injuring Own Body, or Another's with Assent—Abortion.—The Supreme Court of Errors of Connecticut says, in the case of State vs. Carey, where there was a conviction of an attempt to produce a criminal abortion, that, ordinarily, a man may injure his own body by his own hand or the hand of an agent, without himself violating the criminal law. And the agent who injures another's body with such assent may commit a crime of which the injured party is not guilty. A murderer can not justify himself by proving the assent of his victim. Non-interference with a man's control of his person is not extended to the disposition of his life; but taking one's own life is a thing distinct from the crime of murder. If a man in a moment of weakness should assent to the opening of a vein by another for the purpose of ending his life, and, when in the immediate expectation of death, should make a statement of the facts attending the assault, it would hardly be asserted, on trial of his assailant for felonious killing, that the dying declaration must be received with all the infirmities attending the testimony of an accomplice in the crime. This distinction between a man's injuring his own body himself, or assenting to such injury from another, and the crime that may be committed by another in inflicting such injury, has been strongly drawn in crimes akin to the one under discussion. At common law an operation on the body of a pregnant woman, with intent thereby to cause her miscarriage, is an indictable offense, but it is not an offense in her to so treat her own body, or to assent to such treatment from another; and the aid she may give to the offender in the physical performance of the operation does not make her an accomplice in his crime. It is a crime which, in the nature of things, she can not commit. And so it has been held, under various statutory forms of this offense, that the victim of an attempted abortion can not be an accomplice in a crime which consists in an operation on her body, with or without her consent, by another person, with intent to produce abortion. Again, the court says that the criminal intent and moral turpitude involved in the violation by a woman of the restraint put on her control over her own person is widely different from that which attends the man who, in clear violation of law, and for pay or gain of any kind, inflicts an injury on the body of a woman endangering health and perhaps life.

Constitutional Limits to Scope of Medical Practice Acts.—The Supreme Court of North Carolina, speaking through Chief Justice Clark, in the case of State vs. Biggs, refers to the incorporation of "The State Medical Society," in 1858-59, and the sustaining, but not without great hesitation, of the medical-practice act, passed in 1885, and says, among other things, that, after the decisions in State vs. Call, 121 N. C. 646, and State vs. McKnight, 131 N. C. 723, moderation and wisdom would have suggested that the matter rest. Those who wished to be treated by practitioners of medicine and surgery had the guaranty that such practitioners had been duly examined and found competent by a board of men eminent in that high and honorable profession, and those who had faith in treatment by methods not included in the "practice of medicine and surgery," as usually understood, had reserved to them the right to practice their faith and be treated, if they chose, by those who openly and avowedly did not use either surgery or drugs in the treatment of diseases. The courts have declared that they possessed this right, and that the legislature could not, under the constitution, restrict all healing to any one school of thought or practice. What is "the practice of medicine and surgery" is as well understood, and its limits, as the practice of dentistry. The courts have also held that of the many schools of "medicine and surgery" the legislature could not prescribe that any one was orthodox and the others heterodox, but that those professing the different systems—"allopathic," "homeopathic," "Thompsonian," and the like—should be examined on a course such as is taught in the best colleges of that school of practice, but that it is not essential that a member of each, or of any special school, should be on the board of examiners. Chief Justice Pearson noted, as of common knowledge, and reiterated, that railroad charters are drafted by "promoters," and hence should be construed most strongly against the grantees and in the interest of the public. The same construction can fairly be applied to act of 1903, amendatory of the charter of this corporation, in whose supposed interests it was evidently drafted, and not solely in the interest of the public. Under the guise of "construction" of those well-understood terms, the "practice of medicine and surgery," the act essays to provide that the expression "'practice of medicine and surgery' shall be construed to mean the management 'for fee or reward' of any case of disease, physical or mental, real or imaginary, with or without drugs, surgical operation, surgical or mechanical appliances, or by any other method whatsoever." That is, the practice of surgery and medicine shall mean practice without surgery or medicine, if a fee is charged. If no fee is charged, then the words "surgery and medicine" drop back to their usual and ordinary meaning, as by long usage known and accustomed. Where, then, is the protection to the public, if such treatment is valid when done without fee or reward? Yet, unless the act confers, and is intended solely to confer, protection on the public, it is invalid. The legislature can not forbid one man to practice a calling or profession for the benefit or profit of another. The act is too sweeping. Beside, the legislature could no more enact that the "practice of medicine and surgery" shall mean "practice without medicine and surgery" than it could provide that "two and two make five," because it can not change a physical fact. And when it forbade all treatment of all diseases, mental or physical, without surgery or medicine, or by any other method, for a fee or reward, except by an M.D., it attempted to confer a monopoly on that method of treatment, and this is forbidden by the constitution. This is a free country, and any man has a right to be treated by any system he chooses. The law can not decide that any one system shall be the system he shall use. If he gets improper treatment for children or others under his care, whereby they are injured, he is liable to punishment; but whether it was proper treatment or not is a matter of fact, to be settled by a jury of his peers, and not a matter of law, to be decided by a judge, nor prescribed beforehand by an act of the legislature. The public has a right to know that those holding themselves out as members of that ancient and honorable profession—the medical profession—are competent and duly licensed as such. The legislature can exert its police power to that end, because it is a profession whose practice requires the highest skill and learning. But there are methods of treatment which do not require much skill and learning, if any. Patients have a right to use such methods if they wish, and the attempt to require an examination of the character shown for the application of such treatment is not warranted by any legitimate exercise of the police power. In this case, the court says, the defendant was found guilty of the following acts, and no more: (1) Administering massage baths and physical culture; (2) manipulating muscles, bones, spine and solar plexus; (3) kneading the muscles with the fingers of the hand; (4) advising his patients what to eat and what not. And all this without prescriptions, without any drugs or surgery. These acts, by the terms of the statute, are harmless and not indictable, "unless done for fee or reward." There is nothing in this treatment that calls for an exercise of the police power by way of an examination by a learned board in obstetrics, therapeutics, materia medica and the other things, a knowledge of which is so properly required for one who would serve the public faithfully and honorably as a doctor of medicine. And the court reverses a conviction of unlawfully practicing medicine and surgery, Justices Walker and Connor concurring in the result.

Current Medical Literature.

AMERICAN.

Titles marked with an asterisk (*) are abstracted below. Titles of articles will be listed but once, though the articles appear later in other journals.

Medical Record, New York.

February 20.

1 *Heart Syphilis. I. Adler.
2 *High-frequency Currents in the Treatment of Skin Diseases. Charles W. Allen.
3 *Medicolegal Aspect of Accidents Caused by the Roentgen Rays. Carl Beck.
4 Insomnia. Eliot Gorton.
5 Common Duct Stone Associated with Acute Septic Cholangitis. George E. Brewer.
6 Case of Choroidal Inflammation, with Permanent Loss of Vision, Caused by Excessive Use of the Eyes During a Comparatively Short Period of Time. D. B. St. John Roosa.

1. **Heart Syphilis.**—From his study of the subject, Adler holds that syphilis of the heart is not rare, but rather common. It is often possible to make a diagnosis of heart syphilis with exactness, but more often the diagnosis is not absolute. He holds, however, that we should take into account syphilis as a possible factor in every case of heart disease and at all ages. He would not imply by this that every case should be subjected to iodid of potash or mercurial inunctions, but it should be perfectly clear to us why syphilis should be excluded. The patient should have the benefit of the doubt, as in certain nervous diseases. Possibly heart disease should also be considered in every case of syphilis, and the same made the object of careful and constant observation. The pathologic changes may be quite advanced when they produce perceptible disturbances, and the likelihood of relieving the condition is the greater the earlier the specific process is understood. One must not look for pronounced physical signs in the early stages, and in every examination of a syphilitic patient close attention should be paid to the heart, and he should be discharged only when it is insured that the specific disease has disappeared and the heart is as far as possible in normal condition.

2. **High Frequency Currents in Skin Diseases.**—Allen defines and describes the method of application of high frequency currents in skin disorders, gives a summary of 175 histories of which he has records of the use of these currents, and also reviews the opinions and statements of European authorities on the subject. He holds that these currents are a decided advantage in skin diseases, but especially in connection with other measures, and are curative in a restricted class of cases. In the larger class they aid in relieving the symptoms, namely, those attended with pruritus. On the whole, high frequency currents are inferior to the *x*-ray in skin work, but the two go well together.

3. *The X-Rays.*—Beck reviews the lesions produced by the *x*-rays, especially from a medicolegal point of view, and insists on the importance of making applications carefully and suited to the case. Under modern methods the chances of serious damage are greatly lessened, and the fact that inflammation produced by the *x*-ray is a necessary accompaniment of the therapeutic effect in many cases is also emphasized.

7. **The Administrative Control of Tuberculosis.**—The measures that are required for the administrative control of tuberculosis are stated by Biggs as follows: 1. Compulsory notification and registration of all cases. This does not require any action on the part of the authorities unless it is absolutely necessary. 2. Facilitating early and definite diagnosis by affording means of free sputum examination in case of suspected disease. 3. Educational measures, both for the profession and public, on the subject of tuberculosis by circulars, agitation in the lay press, lectures, etc. 4. The visitation of consumptives at their homes and the giving of verbal instruction and leaving circulars and directions how to manage the disease, also to see to the removal of cases if necessary. 5. The disinfection or renovation of rooms or premises which have been vacated by consumptives by death or removal. A trained medical inspector should be sent around. Where the walls and ceilings of the premises are filthy or in bad condition, renovation by the owners should be required and the premises should be vacated and their occupation by others until proper measures are taken should be prohibited. He notices at length some of the difficult problems in this respect, such as the frequent changes of residence of consumptive cases, and does not feel sure that eventually notification by the owner of the removal of a consumptive will not be necessary. 6. Provision should be made for repeated visits to cases in tenement houses when the patient can not be removed to an institution. This can best be done by trained nurses. 7. Suitable food should be provided by the sanitary authorities where the patients are in such destitute circumstances that proper nutrition can not be secured. 8. The sanitary authorities should provide three classes of institutions: free dispensaries for ambulatory cases; hospitals for the care of advanced cases, to receive patients discharged from other institutions, or cases living in lodging houses or inmates of public institutions not affording facilities for their care, and cases that have been removed from their homes on account of the danger of communication; also those that can not otherwise be treated at home. Thirdly, sanatoria in favorably situated country districts for the treatment of early and incipient cases. Patients discharged from such sanatoria are valuable factors for the education of others. 9. The sanitary authorities should issue regulations applicable to public institutions as to the care of consumptives, including under this not merely the hospitals but penal institutions, homes, asylums, etc. 10. There should be regulations enforced prohibiting spitting in public places, conveyances, sidewalks, etc. It has been the custom also in New York to communicate with the attending physicians in cases of tuberculosis to inquire as to the progress of the case, to supply sanitary cuspidors, and thoroughly inspect and study the tenement-house region. It has been said of late years that the decrease in the mortality from consumption has been to a certain extent due to reporting these deaths under the head of pneumonia. An investigation was made as to this point with the result of finding very few pneumonia deaths that could properly be attributed to consumption. The investigation is still being continued, and whenever there is reason to believe that a death has been improperly credited, a change is made in the reports. Biggs does not believe that the great and rapid fall of the tuberculosis death rate is a result of false diagnosis.

8. **House Infection of Tuberculosis.**—Flick points out that tuberculosis is only communicable within confined quarters, and that the house is the essential element of communicability. It prepares the soil for the tubercle bacillus, and furnishes the amount of contamination which is necessary to overcome the resistance of the individual. The workshop is another common means of spreading the disease. Enclosures, such as hotels, churches, public halls, places of amusement and public conveyances where the public stay but a short time, are very unlikely to convey the disease. Consumption can properly be called a house disease.

12 *Clinical Importance of Aerophagia. Heinrich Stern.
13 *Some of the More Unusual Results of Movable Kidney. Charles P. Noble.
14 *Sex Differentiation and Education. William Lee Howard.
15 Osteomyelitis. Howard J. Williams.
16 *Artificial Fluorescence of Living Tissue in Relation to Disease. (Concluded.) William J. Morton.
17 *Roentgen Rays in the Treatment of Pruritus Ani. J. Rawson Pennington.

12. **Aerophagia.**—*Stern thinks this habit or condition has been generally too much overlooked in the human species. It is a common veterinary affection, and the crib biting of* horses finds its analogy in certain hysterical women. In most of the subjects, however, some obstruction in the upper respiratory vessels or asthmatic contraction of the lung tissue seems to predispose. The symptoms generally appear after eating. The patient feels a sense of weight and tension in the gastric region and frequently inodorous eructations occur. The volume of expelled gas is sometimes enormous. In the confirmed aerophagic the gastric symptoms much resemble those of pneumatosis on the basis of motor insufficiency of the organ, differing little from the phenomena of excessive gas formation in the stomach and its retention there. In the aerophagic, however, the gas is more or less odorless. During its presence in the stomach the patient may have shortness of breath, cardiac palpitation, cephalalgia and vertigo. Anorexia and vomiting are of frequent occurrence, together with weakness and emaciation. Stern believes, however, that active extensive work in the open air and overindulgence in outdoor sports are the most frequent causes, and gives illustrations from bicyclists and baseball players. The aerophagic condition, however, is not limited to the stomach. The air passes into the duodenum and other portions of the intestinal tract, and he knows of a number of cases of suspected typhoid, appendicitis, etc., due to this cause. In the hysterical case the air may be thrown out almost immediately; in fact, may not go below the esophagus. When the attack can not be abated and the hysterical patient is used to it, the condition need not be combated very much. Habitual air swallowers hardly ever seek the services of a physician and submit reluctantly to treatment. Moral treatment must be largely relied on in hysterical cases. In the non-hysterical the stomach tube should be employed whenever practicable, followed by irrigation with large quantities of water, to which has been added chloroform water about 10 c.c. per liter, followed by a prescription of bismuth, salicylate and menthol. Occasionally emetics may be employed and turpentine in emulsion. Aromatic spirits of ammonia, well diluted, will aid in the expulsion of gas from the intestines. In case there are cramps from compression of the air in the intestines nothing but ice and water should be given until the small intestines have been completely evacuated. Opium may

have to be resorted to for severe pain. He generally gives castor oil in emulsion for pronounced intestinal tympany following air swallowing. Rest in bed is imperative in intestinal air accumulations, and when there is no doubt as to the real condition he prefers hot fomentations. Massage might be injurious. If there is no marked improvement, attention should be given to food, and it should be of non-fermenting character and in small quantity.

13. **Movable Kidney.**—The unusual symptoms here noted by Noble are Dietl's crisis from the torsion of the kidney on its vessels, hematuria from the same cause, a sense of dragging from the traction on the vessels and adjoining structures, presence of albumin and casts, usually hyaline casts, in the urine as the result of congestion of the kidney due to interference with its circulation. His experience does not confirm Edebohls' statement that movable kidney tends to chronic nephritis, but on *a priori* grounds this would seem probable. Illustrative cases of the different complications are given. His object in presenting the paper is to emphasize that, while the usual symptoms of movable kidney are more or less general, there are distinct local lesions which can not be disregarded.

14. **Sex Differentiation and Education.**—Howard insists on the difference in the mental qualities of the two sexes, and the bad effects of ignoring these in the popular systems of education at the present time. He is not an advocate of coeducation.

16. **Artificial Fluorescence of Living Tissue.**—Morton concludes his paper with reports of cases in which he has used a method of producing fluorescence of the internal organs by medication, he thinks, with advantage, including cases of Hodgkin's disease, carcinoma of the breast and papillomatous growths in the abdomen, etc. He thinks he has made out a fair *prima facie* case for the thorough investigation of this method of treatment.

17. **Pruritus Ani.**—Eleven cases are reported by Pennington in which the *x*-ray was employed for this distressing condition, some of which had been treated ineffectually by various specialists. He thinks the good results in these cases are worth recording. The patients had practically no internal or local treatment during the exposures, though he would not recommend the method to the exclusion of all others.

February 20.

18 *The Life Cycle of Ameba Coli in the Human Body: A Preliminary Note. Charles F. Craig.
19 *Medical Treatment of Diabetes. W. H. Thomson.
20 *The Retinal Symptoms of Vascular Degeneration. L. A. W. Alleman.
21 *Posterior Gastroenterostomy, by a Modified Maunsell's Method, with an Entero-enterostomy by the Hartley Method. W. L. Wallace.
22 Roentgen Ray Treatment of Diabetes. Clarence E. Coon.
23 Hour-glass Contraction of the Uterus. Charles F. Beeson.

18. **The Ameba Coli.**—Craig finds in the amebæ, stained by the modified Wright's method, some chromatin patches which appeared to him to be spores. He believes that the *Ameba coli* undergoes reproduction by sporulation, and that this most adequately explains the persistence of the ameba infection. If these sporulated patches were encysted it would still better explain the persistence of such infection. He reviews the different points which have been urged for differentiating the *Ameba coli* from other amebæ, such as its size. He can not himself confirm the observation that the large size is the ameba of dysentery. Some authors have endeavored to classify these organisms by their phagocytic action. He thinks this is a very unlikely point on which to base a classification. The occurrence of amebæ in apparently healthy intestines has been used as an argument for the existence of pathogenic and non-pathogenic varieties. Craig holds that this claim is absurd, as other parasites are also found without producing their pathogenic infection. That amebæ are present in healthy individuals may imply a loss of virulence on their part or immunity on the part of the bearer. As far as he has been able to observe, such amebæ occurring in the apparently healthy intestines are identical with those occurring in dysentery. He thinks any attempt to classify the pathogenic and non-pathogenic forms will lead to confusion and be of no advantage.

19. **Diabetes.**—Thomson would class any glycosuria lasting more than a year as diabetes and as a serious disorder. For medicinal treatment he would throw out purely functional remedies such as opium, that is, those that do not affect structure, and employ others that do. Among the latter he mentions cod liver oil, which he finds diminishes the sugar and the excess of urea eliminated when it is taken freely and is well borne. Next to this he would mention iron. He tries to give diabetics all the iron they can take, together with all the fresh air they can get. To avoid constipation he would use the old-fashioned Hooper's pills, of which he gives the formula. He would also use drugs falling in the class of so-called medicinal antiseptics, among which he includes arsenic. Other drugs used are sodium benzoate, bismuth salicylate, etc. Alkalies in the form of mineral waters hold a deserved place in the treatment of diabetes, but it should be remembered that their continued use tends to a wasting of flesh, and hence they should not be given to any one losing flesh. In case of diabetic coma, he calls on the most trustworthy diuretic that we have, namely, prolonged intestinal irrigation with normal saline solution.

20. **The Retinal Symptoms of Vascular Degeneration.**—Alleman finds from a study of cases a certain number of fundal appearances which indicate vascular degeneration. In the first class the only thing is a tortuosity of the smaller retinal vessels. In the second class the same condition with more or less bending at the crossings is observed. In the third group some evidence of organic change in the vascular walls can be made out. The curve at the crossings is more pronounced, and a slight haze can be made out on either side of the red line of the upper vessel. He includes in the fourth class all cases presenting advanced vascular disease, such as hemorrhagic, albuminuric and diabetic retinitis. The physical signs which are the first evidence of disturbed nutrition are due to a higher peripheral tension associated with improper elimination, entailing simple tortuosity of the smaller vessels. There may be with this a general lassitude, headache, vague nervous symptoms, etc., and urinary examinations show a diminution in the elimination of urea. As to whether this is an important factor, he is not sure, though it may be a fair guide. In the second group there is spastic contraction of the retinal vessels, which may accompany hemicranias and neuralgias. The patient's general condition may vary from perfect health to nervous prostration, and the urinary findings differ but slightly from those in Class 1. In the third group there is generally some discoverable evidence of vascular degeneration; the radials offer a little more than the normal resistance, and there is frequently a discoverable cardiac hypertrophy. He tabulates a large number of illustrative cases in which the urinalysis and retinal findings are both given. He thinks the field of observation is a wide one and should be cultivated.

21. **Posterior Gastro-enterostomy.**—The steps of the operation employed by Wallace are given with illustrations as follows:

1. The abdomen was opened and the usual investigation made.

Posterior gastroenterostomy necessitates pushing the jejunum through the transverse mesocolon and uniting it to the posterior wall of the stomach.

2. The transverse colon with great omentum was pulled up and an opening torn through the transverse mesocolon, exposing posterior wall of the stomach.

3. The jejunum, about 8 or 10 inches from its beginning, was picked up and the funis clamp was placed on its antimesenteric border with the long axis of the clamp in the long axis of the gut, pulling the bowel well through the clamp, so as to grasp about 2 inches by ½ inch. A pair of artery forceps was snapped on the funis clamp to serve as a handle in further manipulations, and to make it impossible for the funis clamp to come open.

4. The clamped bowel was pushed forward through the opening in the mesocolon and against the posterior wall of the stomach, crowding the stomach far out of the abdominal incision, where it appeared as a dome, through the double wall of which the clamp could easily be felt.

5. A 2-inch vertical incision was made through the anterior wall of the stomach, and the clamped bowel was pushed through this opening, invaginating the posterior wall of the stomach before it.

6. The posterior wall of the stomach was cut transversely, letting the clamp push through, and hatpins were passed under the clamp through the posterior wall of the stomach and the intestine, holding their serous surfaces securely together, and allowing them to be drawn far out, invaginated through the opening in the anterior wall of the stomach.

7. The forceps holding the funis clamp were taken off, the bowel opened by cutting under the funis clamp, and the edges of the intestine and the posterior wall of the stomach were overcast with fine silk, as in Maunsell's operation.

8. The hatpins were pulled out. Half of a Murphy button was dropped into each arm of the intestine, and then the posterior wall of the stomach, with the intestine anastomosed, was allowed to drop back through the opening in the anterior wall of the stomach, and the opening in the anterior wall of the stomach was then closed.

9. The anastomosis was examined from beneath the transverse mesocolon and the halves of the Murphy button were pushed together, cutting over their cylinders (Hartley method) and the abdomen was closed without a drain.

The method, he thinks, is rapid and safe, and the bowel can be clamped and pushed through the transverse mesocolon and passed up through both walls of the stomach quicker than the process can be described. The parts are so securely held that *to overcast the edges after the Maunsell method requires a* few seconds only. In the case reported the method was entirely satisfactory.

24 *Remarks on Cholecystectomy and Cholecystostomy, with Special Reference to Their Comparative Safety and Efficiency in the Treatment of Biliary Affections. Maurice H. Richardson.
25 *Cholecystostomy and Cholecystectomy. A Study of a Certain Series of Operations. Charles L. Scudder.

24. **Cholecystectomy and Cholecystostomy.**—Richardson discusses the two operations, cholecystectomy and cholecystostomy, as compared with each other in respect to danger, efficacy in the prevention of recurrence of gallstones, advantages of drainage and the future possibilities and difficulties of each. As regards the danger, he thinks cholecystostomy is the safest, but the dangers are not excessive in either operation. The removal of a comparatively normal gall bladder in experienced hands probably does not add materially to the risk. In very decidedly abnormal gall bladders, such, for instance, as an adherent, friable, thickened septic organ, with presumably a thickened, strictured duct, the condition is more formidable and the difficulties of drainage may be much greater. When the gall bladder is thickened and contracted, when its fundus is far removed from the abdominal wall, the difficulties of drainage, on the other hand, may be greater than those of extirpation. Drainage is also often desirable, even if extirpation of the bladder is advisable. As regards the prevention of gallstones, he thinks they seldom if ever recur excepting in the gall bladder, but recurrence in his observation is rare. As regards the liability to re-formation, the facts favor cholecystectomy rather than cholecystostomy, but the weight of this argument is light. Drainage of the biliary passages is the one great benefit to be gained by operation. He thinks the escape of bile from the wound for two or three weeks does more good than anything else connected with the operation, and any method that fails to provide this fails in an important element of permanent success. It is true that drainage of the biliary passages may be effected after the removal of the gall bladder, through the cystic, common or hepatic ducts, but the operation is not as easy or safe as might be anticipated. To hunt for the hepatic duct after the isolation of the gall bladder and cystic duct is no small operation in itself, and the cystic duct is sometimes so small that it will not admit anything but the smallest probe and the valves prevent its introduction. The hepatic duct, unless dilated by obstruction below, is too small for the introduction of anything but the smallest tubes and it requires a long incision to find it. It will take a good deal, he thinks, to convince him of the wisdom of drainage in these ducts as against so safe and efficient a method as cholecystostomy. Under certain conditions, drainage through the hepatic duct must be used, no matter what the operation is, when drainage through the gall bladder has been ineffectual or unduly difficult, and in gallstone impactions of the common duct hepatic drainage is, of course, essential. If drainage is essential in gall-bladder surgery, cholecystectomy should never be performed in a comparatively normal gall bladder. When the gall bladder is abnormal—infected, contracted—it should be removed for reasons connected with its own pathologic condition. Yet he has been surprised to see how many deeply infected gall bladders have healed after cholecystostomy. He can not escape the conclusion that cholecystectomy without drainage is an incomplete and dangerous operation, and that biliary drainage through anything but the gall bladder is attended by grave risks of remote trouble. The great difficulty of secondary operations on the biliary passages, especially drainage after cholecystectomy, has been frequently impressed on him. The most important objection to extirpation of the gall bladder, when the cystic duct is ligated, is the loss of the benefits which follow prolonged drainage. The complications that occur after extirpation of the gall bladder have been due to interference with the drainage. Unless it should appear that total obliteration of the organ diminishes rather than increases post-operative complications cholecystectomy must remain the operation of necessity rather than of choice.

25. **Cholecystostomy and Cholecystectomy.**—Scudder's article is an analysis of 16 cases which are reported in detail. He formulates his opinion as regards the two procedures in brief as follows: Cholecystostomy should be done in cases of gall bladder and bile-duct surgery when quick drainage is needed for the deeper ducts and when the surgeon is not absolutely sure that the deep ducts are entirely free. Cholecystectomy should be done in cases of acute cholecystitis, in cases of cholecystitis resulting in grangrene and empyema of the gall bladder, in small contracted and infected gall bladders which are functionally useless and will not be of service in facilitating drainage, and in all cases in which the surgeon is sure that the deeper ducts are unobstructed.

26 *Cataphoresis, with Special Reference to Its Value in the Treatment of Malignant Disease. F. O. Marsh.
27 Ductus Pancreaticus (Ductus Hofmanii Wirsungii). Byron Robinson.
28 *Hypodermatic Medication in Italy. Charles A. L. Reed.

26. **Cataphoresis.**—Marsh describes the methods of cataphoresis, mercuric and zinc, asserting that experimental tests tend to establish the claim that cataphoresis offers unique and special advantages for the destruction and disinfection of morbid and malignant growths *in situ*. It has, he thinks, in many cases advantages over removal *en masse* by the knife, curette or actual cautery. Except in superficial growths, its action is quicker and more penetrating than the *x*-rays, but to obtain the proper results application must be made through the action of a powerful current somewhat prolonged, and used under anesthesia. It is, of course, powerless against anything but local conditions, but here, however, the ultimate results, as obtained by Massey in over 60 unselected cases of malignant disease, seem to be far superior to those of cutting operations.

28. **Hypodermic Medication in Italy.**—Reed calls attention to the greater employment of hypodermic medication in Italy, as observed by himself during a recent vacation spent in Italy. In that country the method is employed not only for the ordinary remedies thus used elsewhere, such as morphin, strychnin, etc., but for iron, arsenic, mercury, phenic acid and a long list of other remedies generally administered by the stomach. The essential feature seems to be in the method of preparation of the remedies. Whether simple or compound, they are put up in solution, carefully sterilized and kept in glass tubes, blown shut, each tube with a capacity of a cubic centimeter, containing a single dose. When administered, the slender neck of the tube is broken off and the contents sucked out through a platinum needle into the syringe, and the drug administered under the skin in the usual way, the puncture and depth being determined by the character of the remedy used. Iron is probably of foremost importance thus used, and it is employed in the anemias of various kinds; also in cases where a general tonic or iron treatment is required for other reasons. Other remedies mentioned are iodin, mercury, etc., and among the more unusual ones are trinitrin as a

vasodilator, paraldehyd as a sedative and hypnotic, hydrastin as a hemostatic, etc. He adds, in conclusion, that this form of medication is well worthy serious consideration.

Atlanta Journal-Record of Medicine.
February.

30 Address, Atlanta Society of Medicine. Alex. W. Stirling.
31 *Some Advantages of Stapler's Rarefier in the Treatment of the Ear. Maury M. Stapler.

31. **Stapler's Rarefier.**—Stapler describes his instrument for treating aural affections. It consists of a small air pump and a tubular metal bridge from which five tubes pass, one to the air pump. The others are applied to the external meatus on each side and to the nasal orifices. The ear tubes can be held by a wire spring; the nasal tubes can be held by the patient. The mechanism of the apparatus is the inflation or the rarefication of the air in the aural passages, and the equalization or otherwise of pressure from both sides of the tympanum. He claims many advantages for it, improving the circulation and relieving abnormal conditions. A number of cases are illustrated where it has been used. Of 24 cases of congenital deaf-mutism, 10 have been made to hear and talk, and 8 others still under treatment have a practical degree of hearing and speech, and can use the telephone. Some of the deaf mutes were cured by one treatment. One child, deaf from measles, was cured in ten days.

32 *Gastritis. Achilles Rose.
33 Diagnosis and Treatment of Chronic Stone Impaction of the Common Duct. John J. McGrath.
34 Gall-duct Obstruction from a Medical Point of View. Thomas E. Satterthwaite.
35 Hydrotherapy, Electricity and Massage in the Treatment of Diseases of Children. Herman B. Sheffield.
36 Ductus Bilis (Biliary Ducts). Byron Robinson.

32. **Gastritis.**—Rose sums up his paper substantially in the following propositions: Gastric catarrh is an impossibility, and erosions of the stomach in most instances are of no clinical importance. Washing out the stomach has been overdone. Olive oil introduced into the stomach has proven of great value in pyloric stenosis. Chronic gastritis is often associated with gastric atony, and symptoms are attributed to gastritis which are sometimes in reality symptoms of gastroptosia. With pronounced gastroptosia and nervous symptoms, the former condition should be first relieved. There is no gastritis produced by mold without gastroptosia. Atonic gastritis deserves more attention than it has received. Symptoms attributed to gastric neurosis are in many cases caused by atonia gastrica.

38 Tunica Muscularis Ureteris. Byron Robinson.
39 Remarks on Salt. W. B. Parsons.
40 Typhoid Gangrene of the Lower Extremities. One Hundred and Thirty-four Cases. Spontaneous and Surgical Amputations (and Historical Résumé). Merrill Ricketts.

37. **Intubation.**—Waxham describes the instruments used in intubation and discusses their limitations. He speaks strongly in favor of the original O'Dwyer tube as being in every way the best fitted, and criticises all modifications that have been made on it. There are many instruments in use on the market, poorly constructed and devised, that should be condemned. Intubation is a difficult operation, requires special training and the best apparatus. It will meet with best results with early and repeated use of antitoxin.

48 A Painless, Bloodless Cure for Ingrown Toe Nails. Anton A. Frank.

42.—See abstract in THE JOURNAL of January 30, p. 329.

44. **Orthopedic Geography.**—Test analyzes the statistics of orthopedic cases in the dispensaries of Chicago, describing also the physical conditions, and concludes that rickety and tuberculous cases each constitute about one-third of the orthopedic cases presented at the Chicago dispensaries. Rickety deformities are commoner in foreigners, especially those from warm countries, living in close quarters. Tubercular deformities are more common in the Anglo-Saxon and foreigners from cold climates. In the region of the Stock Yards, joint tuberculosis constituted 40 per cent. of all deformities, against less than 30 per cent. for other parts of the city. This he attributes to the infection from the great number of tuberculous animals in the Stock Yards. Congenital deformities appear to be commoner in the more highly civilized peoples. These results are based, of course, on a partial study of the cases in Chicago, but he thinks the general results would be the same with more extended study.

46. **Dysmenorrhea in Nulliparae.**—Several illustrative cases are reported by McEwen, who concludes that the condition is due to an undeveloped uterus and more or less local stenosis. The poor drainage and venous stasis ultimately set up an endometritis. This produces a spasm of the sphincter of the internal os, causing the retention of blood in clots which are expelled by labor-like contractions. The heavy, anteflexed fundus causes vesical irritation. Ovaritis is of later development by the extension of the inflammation. Thorough dilatation and curettage should be done in all cases where improvement of the general health does not relieve the patient. In severe cases, further repeated dilatation with the Palmer dilator, or the wearing of an intra-uterine stem is required to permanently relieve the patient. Douching and depleting tampons are practically useless for the uterine condition, but are valuable if the ovaries are enlarged and painful. There is no tendency to spontaneous cure in most cases, and early treatment is advisable. The fact that pregnancy is Nature's cure for the undeveloped uterus should not cause the postponement of the relief afforded by simple operative treatment. These cases, in fact, are usually sterile and require dilatation and curettage to cure the endometritis before they will become pregnant.

61 Report of Five Cases of Tumor of the Brain, with Operation. William G. Spiller.
62 *Discussion on the Surgery of Tumors of the Brain, with a Résumé of the Operative Records of Four Craniotomies. Charles H. Frazier.

49. **Gastro-enterostomy.**—Deaver reviews the conditions calling for gastro-enterostomy, including malignant disorder, bleeding from acute or chronic ulcer, marked inflammation associated with ulcerations and the contractions which they produce, extensive dilatation due to strictures, and fistulas between the biliary tract and the stomach with adhesions, intractable cases of chronic gastritis with multiple erosions at the pyloric region, hemorrhage, Reichman's disease in which the irritation of the highly acid gastric juice causes erosion of the pylorus and fissures—gastro-enterostomy places the organ

at rest—tetany, as suggested by Weir, and acute dilatation where lavage has failed, as suggested by Mayo Robson. Of the various operations he speaks favorably of the posterior method and also of Roux's operation, which he says seems to offer many advantages. He has not used the elastic ligature or Connell suture nor does he use clamps. Fowler's method of entero-enterostomy for the prevention of a vicious circle is mentioned, but Deaver does not consider that it should be done in every instance. He thinks simple posterior gastrojejunostomy is more rapid, safer and perfectly efficacious in the great majority of cases. His future method, he says, will be to perform the posterior method of anastomosis or the Roux Y operation, and in the event of vomiting following the former method, he will reoperate, divide the afferent limb just below the stomach and implant it, as in the Roux Y, into the efferent limb, some 10 or 15 cm. below the stomach, closing the shallow sac above close to the anastomotic opening. The after-treatment of gastro-enterostomy is of the greatest importance. Shock, vomiting and pneumonia should be guarded against. He uses the hot-water bed, hot bottles and a cotton jacket during the operation, with the greatest care in anesthesia. In shock, before all other remedies he uses saline solution by the bowel, at first combined with whiskey, and later intravenously, if the patient's condition demands it. Vomiting is dreaded, and while he usually allows liquid food eighteen hours after the operation, any nausea is an indication for its discontinuance and substitution of rectal feeding. For the vomiting, the best treatment is gastric lavage, using small quantities of water at a time, and giving absolutely nothing by the mouth. He thinks careful suturing is a better safeguard against peritonitis than any mechanical appliance.

50. The Nervous Complications of Smallpox.—Aldrich's article is largely a review of the literature. He thinks we have as a complication or sequel of smallpox a disseminated encephalomyelitis which possesses clinical features and pathologic changes entitling it to be considered as a distinct entity, and that it is sufficiently frequent to demand a special study. It also occurs with other infectious diseases. Of the 15 cases that he has found in the literature all presented more or less ataxia in the four extremities, most marked in the legs, slowness and awkwardness of movement, slow, monotonous, explosive speech, faulty articulation, varying degree of mental degradation and a decided tendency toward recovery. Several cases are reported.

57. Urinalysis in Pregnancy.—The relation of the condition of the urine to puerperal eclampsia is the subject of Willson's article. In answer to the question whether eclampsia can be guarded against by careful attention to the condition of the urine, he thinks the following conclusions are warranted:

> 1. Careful urinalyses should be carried out in all cases of pregnancy at frequent intervals, and with increased frequency as term is approached. 2. The most dependable indications of impaired renal function and of probable eclampsia have been shown by general experience to be the presence of decided quantities of serum albumin, the diminution of the eliminated urea, and the presence of a microscopic renal sediment (*casts, renal epithelium, blood,* etc.). The character of the latter, when accompanied by the well-known clinical signs of nephritis, always constitutes a working basis for an estimate of the probability of imminent danger. 3. Even if the urine appear perfectly normal the possibility of eclampsia must be considered, especially in young women. Eclampsia in such cases is of equal severity with that of cases in which the urine has given due warning of impaired renal functions. 4. When eclampsia supervenes on labor in a subject with previously (apparently) healthy kidneys, the tendency subsequently is toward a return to normal renal functions if the patient survives. This circumstance would seem to indicate still more strongly that the kidneys may actually have been normal up to the time of a temporary embarrassment and suspension of function. 5. Until the nature and ultimate cause of uremia and eclampsia are more thoroughly understood, it would appear that urinalysis, though not an unerring guide, is our most favorable index of the condition of the kidneys and our most trustworthy source of information as to danger from such forms of toxemia. 6. The prognosis seems to be vastly improved if eclampsia be combated by generous bleeding, followed by venous transfusion with normal salt solution. These measures reduce and dilute the poison in the circulation, and relieve the cardiac distress. Free diaphoresis and purging are, of course, indicated.

62. Tumors of the Brain.—Frazier's article concludes with a summary of the operative records of cases reported. He sums up, in brief, as follows: 1. The prophylaxis of shock should be specially cared for. This best reduces the mortality. The most important measures are the avoidance of prolonged operation, excessive hemorrhage and unnecessary rough manipulation of brain substance. 2. A given area of brain can be exposed with the least minimum degree of trauma and greatest economy of time by the electric engine. 3. Temporary closure of the carotids in operations on the brain is ineffectual and not entirely safe. It should be reserved for extreme cases and used only on one side. 4. Blood pressure observations should be made immediately before and at varying intervals during the operation. They furnish the most reliable index of the patient's condition, and the only exact method of determining whether the operation should be carried on or not in two stages. 5. Two-stage operation is indicated where there has been a decided fall of blood pressure after relief from intracranial tension, such as follows reflection of the Wagner flap and dura. 6. Lumbar puncture to relieve pressure is a temporary and not altogether safe procedure. 7. Bulging of the brain is one of the most embarrassing things in cerebral operations. A distinction may be made between that following reflection of the dura, "initial" bulging, and that following subsequent exploratory manipulation, "consecutive" bulging. 8. "Initial" bulging is always due to the increased tension exerted by the tumor. It is not always present and often not excessive, and is not likely to be followed by "consecutive" bulging. 9. "Consecutive" bulging is due to the cerebral edema set up in the normal brain tissue by trauma. It far exceeds in magnitude the "initial" bulging, and suggests the absence of a tumor of considerable size at the seat of operation. 10. In order to avoid this "consecutive" bulging, exploration should be carried out most expeditiously. 11. When the edges of the dural wound can not be approximated without undue tension or great laceration of the brain substance, the gap should be closed by a graft taken from the pericranium, provided the tumor has not been found and the accuracy of diagnosis is questionable. 12. When there is every assurance of a tumor being present, but it proves inoperable or was imperfectly localized, no attempt should be made to close the dura, as this would counteract the best palliative effects of the operation. 13. Palliative operations should be regarded as not merely operations of propriety, but should be considered imperative when the tumor can not be found or removed. 14. A statistical study of the results of the last five years is encouraging. The mortality has been materially reduced, and recurrence after operations for malignant growths of the brain is no greater than after operations for malignant growth of other structures.

Physician and Surgeon, Detroit and Ann Arbor.

December.

63 *Report on the Results of the Use of the Elastic Ligature (McGraw) in Fifteen Cases of Gastroenterostomy. Charles B. Nancrede.
64 *Surgery of the Stomach. Cyrenus G. Darling.
65 Comments, Not for Controversy, but for Light. Ephraim Cutter.
66 The Butler Typhoid Epidemic. Guy C. Keller.

63. The McGraw Ligature.—Nancrede advocates the use of this method in gastro-enterostomy, claiming that it is simpler, safer, more quickly performed, requires less complicated instruments and is adapted to the majority of cases that require gastro-enterostomy for their relief. It is contraindicated only in cases where the matter of time is of importance and immediate communication between the stomach and intestine is demanded.

64. Surgery of the Stomach.—Nineteen cases of operations on the stomach are briefly reported by Darling, who insists on the value of operative interference in averting starvation, relieving discomfort and prolonging life. He points out the comparative safety in exploratory work, the low death rate following resection and the comparative safety of gastro-enterostomy.

Laryngoscope, St. Louis.

January.

67 *Dependence of Aural Affections on the Nose and Throat. H. E. Smyth.
68 Interesting Laryngo-pharyngeal Tumor. Henry G. Ohls.

67. Dependence of Aural Affections on the Nose and Throat.—Smyth holds that while nasal disease predisposes to oral infection there is less danger than usually thought, and that excepting in specific growths the greatest danger is from disease of the nasopharynx. Many of the ear affections accompanying nose and throat disease may be due to a general tendency, rather than to a direct extension. Nevertheless, to successfully treat aural affections it is a wise precaution to carefully examine the nose and throat and correct any pathologic conditions.

Bulletin of the Johns Hopkins Hospital, Baltimore.

69 *Tuberculosis of the Urinary System in Women. Report of Thirty-five Cases. Guy L. Hunner.
70 The Second Hospital in the Colonies, the "Coole Springs of St. Maries," Maryland, 1698. J. Hall Pleasants.
71 Some Unusual Forms of Malarial Parasites. Mary E. Rowley.

69. **Tuberculosis of the Urinary System in Women.**—From a study of 35 cases in the service of Howard A. Kelly and his associates, Hunner deduces in substance the following: Urinary tuberculosis in women is a disease of early adult life. It is usually primarily in the kidney, though in about half of the cases bladder symptoms are complained of. It is confined to one side in the vast majority. If involving both sides a very painstaking examination must be made of both urines to determine whether the treatment is to be surgical or medical. The disease should be kept in mind in dealing with any symptoms referable to the urinary tract; even such ordinary occurrences as a supposed movable kidney or incontinence of urine should be carefully investigated. Appendicitis and gallstone colic must be differentiated. Any obscure or atypical cases of malaria or typhoid fever should suggest the possibility of the disease. The condition is compatible with long life and comparative health, and macroscopic and microscopic examination of the specimens showed that in some cases there is a tendency to heal spontaneously, but in spite of these facts it is preeminently a surgical disorder. The article concludes with a summarized report of cases.

72. **Epilepsy.**—Sinkler's address covers the subject of the recent advances in the knowledge and treatment of epilepsy, especially the sanatorium treatment. It is not readily abstractable, but is well worth reading.

73. **The Surgical Treatment of Epilepsy.**—DaCosta favors the use of surgery in certain cases, though he admits its hopelessness in the majority. Uncomplicated cases of essential epilepsy should not be operated on, for operation will never cure them, but it is justifiable to relieve special symptoms such as localized headache, etc. Good results have also been claimed with excision of the cervical ganglia of the sympathetic. Kocher, on the theory of increased intracerebral pressure, advocates operation even in this type. Idiopathic epilepsy with focal symptoms, if operated on early enough, may offer some hope of relief, but after two years' continuance the hope of cure is markedly less, as the associated fibers are often hopelessly degenerated. Still, even in old cases if the attacks occur with sufficient frequency as to cause exhaustion and threaten life, the excited cortical centers should be excised. This benefits many, but saves the life of few, and it has the disadvantage of leaving a paralysis, though except as to the finer movements, this is usually temporary. When jacksonian attacks develop in idiopathic epilepsy the treatment should be the same as in dealing with partial epilepsy or focal epilepsy from the beginning. In traumatic epilepsy a careful investigation should be made. It may be merely a coincidence and there may be no localized brain damage. Every operation is an exploratory one. If a scar on the scalp is found it should be excised, as Keen has pointed out that severe irritating impulses from a scalp scar may induce epileptic attacks. With evidences of skull injury or depression, trephining is imperative and somewhat promising. When jacksonian epilepsy has followed an injury in the motor region the chances of effecting a cure are much better than when the epilepsy has followed an injury in the sensory region. When it has followed an injury in the frontal region there is very little hope of cure. He sums up the general conclusions as follows:

> Operations for epilepsy are distinctly disappointing and rarely curative, and are indicated in only a small proportion of cases. They frequently produce temporary benefit. They may save life, but they are not entirely free from danger, and occasionally leave the patient worse than before. The mortality, though small, is not inconsiderable. The actual number of complete recoveries is probably under 5 per cent. No case should be claimed to have been cured until from three to five years has elapsed since the operation. Even after operation medical treatment and supervision should be exercised for a long period of time.

74. **The Psychologic Aspects of Epilepsy.**—Spratling describes the various types of mental disturbance from slight clouding, through *feeble-mindedness, imbecility* to *idiocy* and *epileptic dementia* and *acute confusional insanity with hallucinations,* etc., and also *paroxysmal conditions.*

75. **The Epileptic Before the Courts.**—Chapin finds as a result of observation that epileptics do generally show some mental failure such as defective memory, irritability, a tendency to become suspicious and revengeful, etc., emotional, and sometimes an intensification of the moral and religious side of their nature, and that these changes become more marked during the interval between convulsions as the intervals between seizures diminish. In every medicolegal inquiry where epilepsy is suspected it is essential to establish the existence of a paroxysm, beyond a reasonable doubt, and where epilepsy is raised as a defense, and mental and moral degeneration has actually taken place, and convulsions can be proven, the defense is entitled to acquittal and to be disposed of as provided in such cases. If a person has committed a criminal act, has had epileptiform seizures in infancy or at some period has had an epileptic convulsion and the criminal act was not committed near to or succeeding the seizure, and no mental failure is shown, the best he can expect is conviction with a recommendation to mercy if the charge is proven. The convulsion is not the actual disease, but the outward manifestation of a complex psychic and psychical condition due to disease, vicious habits, traumatism or unfortunate heredity. Where convulsions appear at long intervals experience shows that mental and moral degeneracy sooner or later occurs.

76. **The Private Treatment of Epilepsy.**—Bullard says there is only one form of drug that can be generally relied on, that is, certain bromid salts. The most important thing in the general treatment is suitable regulation of the life. In the mildest cases with little or no mental impairment, it is better to continue the ordinary occupation, but regulating the brain work so as to avoid sudden mental exertion or strain and an excess of worry or anxiety. If the choice of occupation is still before the patient, he would advise such as bring the least mental exertion while affording sufficient regular occupation and healthful environment, such as farming or other outdoor occupations. The digestive functions must be looked after, and he thinks the ordinary mixed diet is suitable for the epileptic. He need not absolutely abstain from meat, but it is important to regulate the quantity of food; there should be no overeating. The teeth should be carefully looked after and mastication attended to. Anything that disagrees with the patient, of course, should not be employed. He should have as variable diet as is compatible with his digestive powers. Alcohol, as a rule, is to be avoided. Tobacco in moderate amount does not seem injurious. Tea and coffee should be limited and their action watched. The epileptic should have all the sleep ordinarily required, but napping in the daytime is to be avoided as possibly favoring attacks. Moderate, regulated physical exercise is best; excess or lack of it is harmful. Fresh air is very important and freedom from mental excitement and shock is essential. Among the bromids he favors bromid of soda, holding that it is perhaps the most satisfactory, but the bromids are only adjuncts to other treatment, such as the regulation of diet, sleep and occupation.

79. **Blood in Epilepsy.**—Pearce and Boston from the blood count of a series of 7 idiopathic epileptics conclude that there is a fairly well-marked chlorotic type of anemia in these cases. There was a leucocytosis also in all but 1 of the 7 cases. There is no conclusive evidence of a change *per se* in the cells themselves, but it is possible that a toxin may be circulating. They report at some length experiments by injecting epileptic blood into rabbits which seem to show that there was a profound toxemia set up in the animals. There was a rise in the hemoglobin and increase of leucocytes, decrease of red blood corpuscles, increase in eosinophiles and decrease of polynuclear cells. It did not produce distinct convulsions in the rabbit, but the blood changes were suggestive of a toxemia. The changes were in striking contrast to those noted in ordinary septic processes where the polynuclears increase and the eosinophiles develop rapidly.

85 Case of Resection of the Elbow, Showing Results of the Operation. Gwilym G. Davis.

82. **Cancer.**—Rodman gives the results of treatment of malignant disease of the breast, which he thinks is too optimistically considered by American physicians. Its death rate is rather larger than it has been estimated by some. He thinks it is conservative, however, at the present time to say that at least one-third of the cases ought to be cured. Malignant disease of the penis is nearly always a carcinoma, and it is a mistake, he thinks, to neglect glandular involvement in the groins whether it is apparent or not. The immediate mortality of the operation should be slight. Rectal growths on the whole are not all hopeless, especially if operated by the perineal route. *He thinks we can get a larger percentage of cures than Butlin* reports, namely, 21 per cent. Carcinoma of the lip is the most hopeful of all malignant disease. The primary mortality may be as large as Butlin estimates, but the proportion of cures reaches 53 per cent., according to his figures. Rodman believes that surgeons at the present time are curing more than one-half of their cases. The operation should be thorough, opening the submaxillary triangle whether apparently infected or not.

83. **Hernia.**—Horwitz would use general taxis for a short time followed by operation, which is not dangerous in strangulated hernia. After inflammation exists, taxis should not be performed. No one method is suitable for the radical cure of all cases; Bassini's method is best for the majority, and Bloodgood's where a large abdominal ring and weakened conjoined tendon exist. Palliative operation is applicable to many selected cases of reducible hernia where protrusion can not be kept in by a truss, and also in some forms of incarcerated hernia. Radical cure may be safely attempted on both rather old and young patients. The truss should be worn after the palliative operation. Where no routine method can be employed the surgeon should do the best he can to remove the neck of the sac on a level with the parietal peritoneum, and if possible firmly close the opening after removal of the sac; he should obliterate the depression of the peritoneum in the vicinity of the internal abdominal ring, bringing the structures in apposition and closing the aperture through which the hernia protrudes. An aseptic result with primary union is essential for the success of radical operations. In case of undescended testicle every effort should be made to save and transplant the organ. For umbilical hernia, Mayo's operation is probably the most satisfactory. Absorbable sutures are preferable to non-absorbable material in hernia operations.

7 *Some Deceptive Abdominal Conditions and the Question of Operation. A. H. Tubby.

1. **Puerperal Sepsis.**—Under this head Horrocks includes puerperal sepsis of the malignant type, puerperal sapremia, pelvic cellulitis, peritonitis, pyemia, phlegmasia dolens and milk fever. The first is the most important and serious, though some of the others may occasionally be fatal. Horrocks names as causes contagion from other similar cases, erysipelas, the handling of dead bodies, suppurating disorders, etc. He believes that some cases occur through no fault of the physician, nurse or other person, but there must be some infection, nevertheless. Meddlesome midwifery of all kinds is objected to. He does not even use the binder, and thinks it is the best plan for the obstetrician to use an india-rubber glove in making his examinations and manipulations. Vulvitis, urethritis or vaginitis, specific or otherwise, should be attended to before labor, if possible. If the labor is already in process when such a condition is found, the physician should do his best by copious syringing before the child is born to wash away as much infectious secretion as possible. Perfect asepsis of the vaginal walls is, of course, impossible, but many of the microbes can be put out of activity. The question arises in sepsis whether it is a sapremia or septicemia, and if there is plenty of milk secretion and lochia, and if the latter is offensive, it is probably sapremia. In such cases it is best to give an anesthetic and remove from the interior of the uterus with a disinfected finger any piece of placenta, membrane or clot or decomposing matter and to follow this by an antiseptic douche. Many cases will improve without this digital exploration, but others require it. If the milk is getting scanty or suppressed and the lochia, too, are diminished or suppressed, and not offensive, and the temperature is high it is probably a grave case of puerperal sepsis and the same course should be followed. He is not sure that curetting the uterus is not a good plan if done early. Antipyretics and germicidal solution to the uterus direct are suggested by some. He has had a large experience with antistreptococcic serum. In some cases it seemed to act wonderfully well, but it fails so often that it is unsatisfactory. He injects subcutaneously 20 c.c. at a time in the anterior surface of the body, under aseptic precautions. It should be repeated so that the patient gets 60 c.c. within the first twenty-four hours, and 20 c.c. twice a day after that. Any local wounds or injuries should be thoroughly treated. He has had no experience with hysterectomy. He thinks it may be successful if done early, but does not think it is likely to become a recognized practice. The same applies to opening the peritoneum and washing out. A physician who has a case of puerperal sepsis should discontinue his midwifery practice, although it is possible for him to thoroughly antisepticize himself, especially his hands, so that he can resume general surgical practice. He insists on the importance of avoiding examinations as much as possible and of not allowing the nurse to make any examinations. If she has already done so, syringe the vagina with a germicidal lotion.

7. **Deceptive Abdominal Conditions.**—Tubby reports nine cases in which various conditions, such as traumatic rupture of the bowels, perforations, pyosalpinx, pelvic cellulitis, etc., were present, but in which the symptoms were obscure at first. He specially remarks on the puzzling conditions in appendicitis, and on the importance of the leucocyte count as an aid to the diagnosis. Where the general symptoms are severe and the leucocyte count over 12,000 or 14,000 he would not hesitate to operate, as suppuration is possible. He thinks that the cases reported teach that many abdominal lesions are latent for a time so far as their symptoms indicate, and that they then suddenly become acute and that cases commencing acutely often subside and apparently progress favorably, but that they later break out again virulently, ending fatally, the favorable opportunity of the latent period not having been grasped. When general symptoms of suppuration are present it is sometimes impossible to show what particular organ is affected, and we have no data on which to commence our exploration. Lastly, there is the danger that if we do find the focus of suppuration we may not be able to limit it and prevent its spread. The important symptoms which we can not neglect are, first, the pulse and temperature, which may be entirely disproportionate to each other (a normal temperature with a pulse rate of 100 or over, or a subnormal temperature with a rising pulse are both abnormal conditions); second, leucocytosis; third, rigidity. Vomiting is a variable sign. If it recurs, in spite of careful feeding, it is not to be underestimated. In the later stages of abdominal disease distension is an important symptom. If it lasts for more than twenty-four to thirty-six hours and is unrelieved by treatment such as turpentine enemas, it is of grave significance. Diarrhea in the course of acute appendicitis is generally a sign of septic absorption and local tenderness is always of value as a guiding point to the site of the lesion. Hematemesis and melena persisting after injury or in association with suspected gastric or duodenal ulcer may indicate operation. The presence or absence of increasing abdominal dullness is an important factor in doubtful cases and effusion of blood beneath the abdominal walls can be taken in account, in consideration of other symptoms as above, as indicating possible laceration of the parts. When the symptoms in the beginning indicate an abdominal disorder and the patient remains ill, careful examination of the chest should be made and the detection of either a pleuritic rub or fluid in the pleural cavities may serve as an indication that mischief is going on and that exploratory operation is called for. Pleurisy and perigastric abscess and subdiaphragmatic abscess secondary to appendicitis are well known to be associated.

9.—See editorial in this issue.

10. **Suppuration of the Labyrinth.**—Milligan describes the processes and reports cases. He lays down the following points as to the guides to operation:

> 1. In any case of suppurative middle-ear disease where well-marked nerve deafness on the affected side is accompanied by frequent attacks of vertigo and sickness and by nystagmus, either constant or intermittent, a careful search should be made for the presence of any fistulous tract leading into the labyrinth. If found such tract should be opened and explored; if not found, however, an exploratory opening through the horizontal semicircular canal or foot plate of stapes is justifiable. 2. In all cases of suspected labyrinthine disease of septic origin the vestibule should be promptly opened. 3. In cases of chronic suppurative middle-ear disease accompanied by the presence of cholesteatoma and erosion of the external labyrinthine wall free opening of the area of involvement should be effected. 4. In cases of suspected cerebellar abscess accompanied by symptoms indicative of labyrinthine involvement the operative pathway should be via the middle and internal ear to the posterior surface of the pars petrosa—in other words, through the median wall of the mastoid antrum. In this way the labyrinth is opened up, the anterior portion of the corresponding cerebellar lobe is exposed, and any extradural abscess lying on the posterior surface of the pars petrosa would at the same time be located and drained.

13. **Cancer in Australia.**—In Australia cancer seems to be excessively prevalent among the foreign born, while the native

born, according to Adams, largely escape. Thus among the Australian born the proportion of death from cancer per 100,000 is 22.6; British born, 203.1, and among those of German, French and Scandinavian birth, it is still higher. Of the foreigners in Australia the Americans seem to be least liable, though far more liable than the native born, the ratio among them being apparently about the same as it is in the United States. Of the provinces or states of the Australian Confederation, cancer seemed to be most prevalent in Victoria and least so in Western Australia. He attributes considerable of the liability to cancer to alcoholism and syphilis. He thinks the comparative immunity of the Australian born is largely due to the character of the indigenous foliage, especially the eucalyptus trees. He has never found any evidence of cancerous disease among the indigenous animals, and aboriginal Australians appear to be practically immune. The theory he ventures to offer and on which his treatment is based is stated by him as follows:

> That the origin of cancer (carcinoma and sarcoma) is not due to a bacterial, parasitic or local cause, but is to be looked for in the blood in the form of an unknown chemical constituent (which, for the purpose of description, I will call "malignic acid"), capable of gradually becoming virulent under certain bad climatic, hygienic, dietetic and social conditions of life, chiefly manifesting itself at its greatest virulence after 40 years of age, the degree of virulence and the age at which it may manifest itself being entirely dependent on the age and constitutional condition of parents at the time the "malignic acid" diathesis is transmitted and according to the mode of living, environment and exposure to the exciting causes after birth. This "malignic acid" when excited into virulence in its passage through the blood stream may attack any soft or bony tissue in any part of the body the physiologic resistance of which has been weakened by one or other of the exciting causes. It matters not whether this tissue be epithelial or connective, a matrix of detached embryonic inclusions; existing benign tumors derived from a congenital, inherited, or post-natal origin; syphilitic, scrofulous, tuberculous or lupoid lesions; ulcerations and lacerations of the cervix uteri; inflammatory deposits; old scars, burns, wounds or skin lesions excited by soot or paraffin; eczema, *ichthyosis*, or any other irritating cause. This "malignic acid" possesses the power by a process of chemical reaction of transforming any of the aforesaid weakened tissue into malignant tissue, having particular effect on debilitated epithelial and connective tissue which has been subjected to prolonged local irritation, attacking and infecting its intracellular matrix and cells. At the same time, it sets free the latter to group together in nests or to migrate through the blood and lymph channels either to escape as excretory products or to become deposited on other distant debilitated parts of the body. I am of the opinion that the various so-called intracellular and cellular inclusions which have been isolated and so fully described by [illegible] Leyden and others to be parasites, and by [illegible] as secretion depositis, are nothing more [illegible] formed remains or deposits (which also for the purpose of description I will term "malignates") of the parent intracellular matrix, some of which has been included in the cells during the process of chemical reaction.

The article is to be continued.

15. Latent Nasal Obstruction.—Under this head Collier includes those cases in which the nasal passages are free during the day, but become obstructed during the night, producing mouth breathing. The cavernous and mucous membrane of the nose becomes mechanically obstructed by the increased intravascular pressure when in the horizontal position and the turbinate bodies approach the septum on either side. The erectile tissue on the floor and lower part of the septum helps to complete the obstruction, and he finds in these cases the groove in the septum which is characteristic. This intermittent nasal obstruction plays an important part in the production and recurrence of polypi.

17. Eczema.—From the facts here laid down and discussed Whitfield concludes that eczema can be caused by external irritants alone when they are sufficiently strong and act long enough. Certain skins are from birth of low resisting power and their owners are specially subject to attacks of eczema. Other skins have some gross and visible defect, such as ichthyosis or diminished or excessive secretion, which exposes them to more frequent irritation, and they therefore suffer in the same way. By repeated irritation or more frequently by a single powerful irritation, the normal skin may lose its resistance so that irritants hitherto inefficient to produce disease are successful. When once the resistance is broken down it can only be restored by prolonged rest and careful protection; while this state of acquired low resistance continues the conditions are indistinguishable from those of congenitally susceptible skins. As regards internal causes he thinks in many cases they are of equal importance, though he doubts whether any one of them is capable of calling forth an eruption in the absence of external irritation. Disorders of the alimentary tract have first rank, and he illustrates this by acne and rosacea forms. He remarks how much more frequently eczema is found in those who are overfed than those who eat too little; this is especially noted in babies. Aside from the question of dyspepsia he doubts whether any special line of diet should produce eczema as a rule. He has seen it as frequently in vegetarians as in others, and has known it to clear up under a minced beef and hot water diet. It is also important that we should not neglect the nervous system. Nervous shock or strain may produce it, also eyestrain, and it is perhaps a question whether the inveterate form of eczema that alternates with spasmodic asthma can not be put under this head. Lastly he mentions the lymphatic cases who are specially liable to such eruptions.

26. Electrolytic Dilatation of Urethra.—Analysis of the 25 cases reported by Desnos shows that electrolysis is not destined to supplant the ordinary methods of treating urethral strictures, but frequently proves an invaluable supplementary procedure. It renders permanent the results obtained with other methods and in occasional cases may be effectively substituted for them. In 16 patients the strictures had recurred after other treatments, but the electrolysis finally restored practically normal conditions. It is absolutely harmless and reduced the relics of peri-urethritis and urethritis, curing them completely in two-thirds of the cases.

29. Acute Spermato-Cystitis.—The possibility that an abscess in the seminal vesicle may perforate into the bladder is confirmed by the case described by Wildbolz.

30. The Janet Method of Treating Gonorrheal Urethritis.—Guiard is convinced that irrigation with potassium permanganate is a marvelously effective treatment of this condition during the first three days. Applied later than this, it is tedious, irritating and even dangerous. The strength to be used should be determined by the reaction of the mucosa in painfulness and secretions, the aim being to avoid such reaction. He warns against using more than 500 gm. of fluid for one irrigation, and mentions that cocain beforehand, by suppressing contraction of the sphincter, much facilitates the irrigation. The fluid should be at a temperature of about 40 C. The irrigations should be made twice a day the first four days and then once a day for four days, unless the gonococci reappear, when two injections a day should be resumed. He prefers a syringe to any other apparatus for the injections.

32. **Chloroform and Urinary Apparatus.**—Guyon does not regard kidney disease as a contraindication to chloroform. The kidneys are more or less quiescent during chloroform anesthesia, and it is eliminated almost entirely in the exhalations.

37. **Epidural Treatment of Incontinence.**—Masmonteil's experience indicates that a cure may be counted on when the primary cause of incontinence of urine in children is atony of the neck of the bladder. When due to cystocele or traumatism the results are less marked. There is first a reawakening of sensation during the day, then recuperation of the tonicity of the sphincter and then gradual subsidence of the pollakiuria. Six out of 10 children were promptly and permanently cured. In 3 cases of incontinence with general paralysis, 1 of tabes and 1 of debility, the results showed that the effect of the injections is felt exclusively by the sphincter. He followed Cathelin's technic, described in The Journal, xli, page 287.

38. **Operative Kidney Affections.**—In Kümmell's experience at Hamburg the mortality in operative cases of kidney affections has dropped from 28 per cent. (in 168 cases), to 8 per cent. (in 98 cases), since the introduction of the new functional tests. As the operation was undertaken in one case counter to the testimony of the tests, the mortality in reality should be regarded as only 4.8 per cent. His material is reviewed in detail.

39. **Absorbable Prothesis for Union of Blood Vessels.**—Payr states that his method of magnesium prothesis in operating on blood vessels has given excellent results in the hands of Exner, Ullmann, Hoepfner and others. Those who have not found it satisfactory did not adhere strictly to his directions. He advocates it as simple, certain and free from technical difficulties. Cuts are given of vessels thus united, showing perfect restoration of the lumen after the use and absorption of the magnesium cylinders.

47. **Recurring Retroperitoneal Lipomata.**—In Heinricius' practice at Helsingfors he has observed two cases of this condition. The tumors originated in the retrocecal adipose tissue and reached enormous dimensions. One patient succumbed after partial extirpation of the second recurrence. The other is well at present after extirpation of the first recurrence. He appends the literature on the subject.

49. **Vagus and Peritonitis.**—Friedländer comments on the fact now established that the local alterations are not the sole cause of the collapse in peritonitis. He has been studying the subject on cats, applying stimuli to the vagus, sympathetic and the medulla, etc. His experiments reveal some of the laws governing the complex phenomena observed, especially the disproportion between pulse and temperature. The sympathetic, he finds, is the medium of the pains, while the vagus is responsible for the behavior of the heart and its blood vessels. He explains in detail the important part played by the vagus in peritonitic collapse. He thinks that the pulse shows when the inflammatory process has invaded the loose cellular tissue containing the nerves, thus showing that the entire peritoneum is becoming involved.

50. **New Method of Treating Femoral Hernia.**—Cavazzani passes two threads through the upper corner of the obturator foramen and through Poupart's ligament. This enables him to draw the ligament over against the horizontal ramus of the pubis. This technic proved admirably adapted for its purpose in the three cases in which he has applied it, as shown in the cuts.

64. **Permanent Cures of Uterine Cancer.**—Flaischlen has investigated the remote results in all the cases of uterine cancer operated on by Ruge and himself between 1885 and 1896 by the vaginal route. Of the total 48, 4 died soon after the operation; 24 have had a recurrence of the cancer, but 20 have shown no signs of recurrence to date. Seventeen of these are permanently cured after an interval of seven to nearly nineteen years. The other 3 died from a casual intercurrent disease in the interim. In 9 of the permanently cured patients the collum was affected, the corpus in 6, and in 2, both simul-

taneously. Among the patients who developed recurrences, 16 died in the first two years, 3 in the third year, and 5 were in good health for four to five years before symptoms of recurrence became apparent. The recurrences were almost all local, in the cicatrix. One of his cured patients was a woman of 30, with an extensive carcinoma involving the portio and entire left vaginal vault, declared inoperable by another surgeon. Enlarged glands could be palpated in the left parametrium. He detached the uterus on the right side and removed with it as much of the left parametrium as possible. He is confident that the enlarged glands were not all removed, but the patient has been in the best of health during the ten years since. If the 3 healthy women who died of intercurrent diseases are included among the permanent cures, the proportion of the latter is 40 per cent., and omitting them, 34 per cent.

66. **Illumination of Vagina and Pelvis During Laparotomies and Celiotomies.**—Frommer gives cuts of the retractors he uses, each of which is fitted with an electric light. He thinks that the instruments answer the purpose better than those devised by Ott (illustrated on page 454 of The Journal of August 23, 1902), as the Trendelenburg position is not required. They can be applied with the patient in any position. The parts are illuminated so perfectly that they can even be photographed by this light. The retractors can be made with one to three lamps as desired, and the whole can be boiled together or the lamps previously removed. They fit close against the convex side of the retractor or are fastened to the concave side with an opening over them for the light to stream through. The wire runs through the handle. The four varieties of these illuminating retractors are illustrated, as they have been used for a few months at Gottschalk's clinic at Berlin with constant satisfaction.

71. **Spurious Hermaphroditism.**—Neugebauer encountered 6 cases of pseudo-hermaphroditism in 1902, in 3 of which the

of the instruments so long that they could not possibly be overlooked. Karl Schröder and Lawson Tait made it a principle to use as few instruments as possible, while Péan used the largest number of any. The smaller the number, the easier the oversight. Neugebauer himself has lately made a practice of having the husband, parent or guardian sign a certificate before an important operation stating his consent to the operation, his knowledge that there is more or less danger connected with such an intervention, and exonerating the surgeon from responsibility in case of suppuration, fistula or any unforeseen mishap, signed also by a witness. He has found that the signing of such a certificate has a very depressing effect on the family and also on himself, but regards this as a minor evil in comparison. He does not exact the certificate in families who he knows to be intelligent and reasonable, but when there is cause to suspect perfidy he invariably insists on it, or declines to operate. Certificates like this were employed in 1883 in one of the German clinics where he served for a time, but they are not in as general use in Europe as he hears they are in America. A surgeon who has once had any experience with a damage suit of this kind soon decides to exact some such protective measure.

74. **Hysteropexy by Suspension of the Round Ligaments.**—Bardescu treats retrodisplacement by making a buttonhole in each lip of the abdominal incision on the median line, and drawing the round ligament through this opening on each side. The abdominal incision is then sutured and the loops of the round ligament are sutured together over it, spread out to give space for three stitches at least. The skin is then sutured. This procedure has been performed on 5 patients, with excellent results. Its advantages are that the ligaments are fastened together, utilizing the strongest part; the support of the rectus muscles is more solid than that afforded by the previous support, and the ligaments still retain all their elasticity and strength. It is similar to Doléris' technic, but

107 Mental Disturbances in Incipient Paralysis. G. Fischer.—Ueber hochgradige generelle Störung der Merkfähigkeit bei beginnender Paralyse. (Commenced in No. 4.)

78. **Evil Results of Deep Incision of Cervix During Delivery.**—Hofmeier remarks that voices have been raised in protest against the danger of hemorrhage from Dührssen's incision of the soft parts to facilitate delivery. No one, however, has published anything in regard to the remote evils of the procedure. In 2 cases recently, a subsequent childbirth proved fatal in one case and without prompt intervention would have proved fatal in the other. The rigidity of the site of the former incisions resulted in rupture of the uterus wall just above the cicatrix. One patient had passed through two normal childbirths between the incisions and the last fatal birth. If the Dührssen incisions are deemed absolutely necessary, at least they should be made on the front and rear aspects, and not on the sides, near the large blood vessels.

80. **Eosinophile Cells in Sputum.**—Hildebrandt's extensive experience has demonstrated that the finding of eosinophile cells in the sputum has no diagnostic significance either for bronchial asthma or against tuberculosis.

81. **New Formation of Bone After Resection of Ribs.**—Baldassari and Gardini resected a part of a rib on dogs and substituted calcined bone in some and simply boiled bone in the others or left the gap unbridged. They found that there was scarcely any regeneration of bone when no foreign bone had been introduced. The calcined bone healed encapsulated like any foreign body, but the bone that had been merely boiled healed in place with an actual regeneration of new bone which had evidently utilized the salts in the foreign bone.

82. **Prognostic Significance of the Pulse in Tuberculosis.**—Sterling has become convinced that a normal pulse beat in pulmonary tuberculosis is a favorable sign. A regular acceleration of the pulse in afebrile conditions is a bad sign, proportionately to the amount of acceleration. The prognostic significance of the accelerated pulse is most important in the first stages of the disease. He has been studying the subject for three years and found that the proportionate mortality was with normal pulse during the first stage, 1; with pulse up to 120, 3.1; and with pulse above 120, 12.1. In the second stage, normal, 1; up to 120, 1.8; over 120, 6.1. In the third stage, normal, 1; up to 120, 1.1; over 120, 1.6. He suggests as an improved method of classifying tuberculous subjects to add the figure representing the constant pulse rate to that representing the first, second or third stage. By this means a much better idea of the actual condition would be obtained. For instance, II-88 would have a more favorable prognosis than I-130. Also III-88 would be more favorable than II-140. When the figures representing the first, second or third stage are used alone, this should mean that there is accompanying fever.

83. **Nervous Enterorrhea.**—Richartz reports from von Leube's clinic the case of a man of 52 who had five to twelve alvine evacuations a day, the passages consisting almost exclusively of a clear, thin fluid, the desires abruptly imperious. There were no gastro-intestinal symptoms otherwise, and during sleep and when traveling in the cars he was free from this enterorrhea. He had taken several courses of treatment at various times and places, but without avail. Treatment addressed to a supposed catarrhal affection had no effect, but a cure was obtained by daily injections of tannin with persevering use of cascara by the mouth. The fluid evacuations gradually diminished, and by the end of the third week the patient for the first time in three years passed the day without a single watery stool. The watery stools recur once in a while even now, but the desires have lost their imperious character, which rendered the trouble so unbearable. Richartz offers a theory to explain the success of the tannin and cascara treatment.

84. **Tubercle in the Spine.**—Oberndörffer differentiated the case described by the evidence of tuberculosis elsewhere, the lack of symptoms pointing to caries of the spine, the pronounced unilateral paralysis soon becoming transformed into paraplegia, the sensory paralysis, at first dissociated and later total, and the aggravation of the condition under extension.

85. **Ovariotomy in Gravida.**—Heil adds to Gräfe's statistics 5 new cases personally observed, and others he has collected, bringing the total to 241. He tabulates the later series, and emphasizes the necessity for careful examination of every pregnant woman who complains of pains or other disturbance indicating some irregularity in the genital sphere. If the diagnosis wavers between an extra-uterine pregnancy or an intra-uterine with an ovarian cyst, a laparotomy is indicated at once. An ovariotomy is by far a lesser evil than the overlooking of an extra-uterine pregnancy, especially for a patient who is not under constant medical supervision. He advocates leaving the tube, if possible, when operating during a pregnancy, to avoid traction on the uterus.

87. **Splenectomy.**—Bayer reports a favorable issue to splenectomy undertaken on a boy of 12 on account of idiopathic hypertrophy of the spleen. Since 1891, 254 cases of splenectomy have been published, all the patients recovering except 54. Classifying the cases, we find the mortality 100 per cent. in "stagnation" or amyloid spleen or hypertrophy accompanying cirrhosis of the liver; in leukemic hypertrophy it was 75 per cent. of 8 cases; in splenic pseudo-leukemia, 0 in the 1 case; in rupture, 34.9 per cent. of 43 cases; 0 in 4 cases of abscess; 0 in 3 of tuberculosis; 0 in 4 of hematoma; 7.7 per cent. in 13 cases of hydatid cysts; 20 per cent. in 5 cases of sarcoma; 50 per cent. in 2 of benign growths; 33.3 per cent. in 15 of torsion of pedicle of wandering spleen; 20.2 per cent. in 89 cases of malaria; 6.9 per cent. in 29 cases of hypertrophied wandering spleen; 17.6 per cent. of 17 cases of Banti's disease, and 9.5 per cent. of 21 cases of idiopathic hypertrophy.

88. **Medical Notes in Central Brazil.**—These notes were taken during a German medical mission in 1898-1900 in the Xingu valley. Mansfeld remarks that the Cuyaba region in particular is an eldorado for specialists who wish to study tropical and cutaneous diseases. He was very favorably impressed with the popular beverage, Paraguay tea, as a substitute for tea and coffee.

89. **Inflammation of Sigmoid Flexure.**—Bittorf's 3 cases all displayed a distinct resistance in the left iliac fossa, more or less sensitive to pressure. The temperature was 37.3 to 38 C. The bowels had been more or less irregular for a long time, generally with obstinate constipation occasionally interrupted with diarrhea. The subjects complained of loss of appetite, depression, general nervous disturbances, more rarely of spontaneous abdominal pains especially in the left lower bowel, which was aggravated by certain movements. The tenderness subsided under bed rest, laxatives and dieting, but the resistance only partially retrogressed.

90. **Early Symptom of Severe Appendicitis.**—Moszkowicz calls attention to the serous effusion in the abdominal cavity, which he has found a constant accompaniment of the severer cases of appendicitis. Out of 46 cases, an effusion was found in the abdominal cavity in 27, and in the others it may have existed and retrogressed prior to operation. He believes that this serous effusion is frequently the first sign of impending trouble, before the patient shows any other symptoms indicating a severe involvement, and liable to occur while he still feels quite well. When it is found, it should be regarded as the precursor of diffuse suppurative peritonitis, a signal for operation at once. The effusion is a sign that a large amount of bacterial toxins has already diffused into the abdominal cavity. It resembles in this respect the edema which accompanies a serious phlegmon on the leg or arm.

97. **Acute Pyelitis in Gravida.**—Häberlin has observed 8 cases of idiopathic acute pyelitis in pregnant women. The onset was stormy, with high fever, lumbar pains and generally

chills, accompanied by signs of bladder irritation. All the patients recovered rapidly in the course of one or two weeks, and no permanent injury seemed to have been done. Treatment should be expectant. If the pressure of the fetal head is causing trouble, this can be relieved by a pessary or appropriate position in bed. Large quantities of fluid should be ingested, with salol and urotropin as disinfectants. Artificial delivery is not indicated, as it would be dangerous during the acute stage, and after this is past there is no need for it.

100. **Origin of Tuberculosis.**—Among the arguments which Oppenheimer presents in opposition to Behring's views are the comparatively small number of children who die from tuberculosis during the first twelve months of life, and also the negative response to tuberculin in infants. Also the rarity of primary intestinal tuberculosis, and the fact that the gray nodules found by Behring in calves have never yet been discovered in children.

105. **Determination of Pressure in Right Auricle.**—Gaertner *replies to Prym that his test should be applied to the most delicate* veins, not to those that have lost their elasticity. For this reason he does not use those in the back of the hand.

110. **Air Embolism.**—Wolff's experimental research on air embolism indicates that death is not due to heart failure as much as to extensive embolism in the capillaries of the lungs, impeding the circulation. He was never able to detect the presence of air in the left heart in appreciable amounts. He offers a new explanation for the sounds heard in the heart after introduction of air in the veins, and reviews 115 works bearing on the subject of air embolism.

114. **Cancer of the Liver and Biliary Passages.**—Fischer emphasizes the fact that liver cirrhosis is noticed as accompanying adeno-carcinoma of the biliary system in 85 per cent. of the cases on record. This with other facts which he adduces, he accepts as testimony that the supposed primary cancers in the liver in reality originate in the biliary passages.

118. **Acute Infections Among the Blacks of West Africa.**—A comprehensive picture is here presented of the acute infectious diseases among the natives of the German state of Kamerun on the western coast of Africa, just north of the equator. Plehn has resided there for 8 years and has wide experience on the subject. *He asserts that tuberculosis is entirely* unknown there to date, even in the surgical form. Pneumonia is very prevalent among the natives, the catarrhal form, but does not seem to affect the Europeans. Articular rheumatism is frequently observed. The negro races display remarkable resistance to wound infections, to gonorrhea, dysentery and malaria, and seem absolutely immune to yellow fever. One tribe, the Duala, seems likewise completely immune to infection from syphilis. He mentions the rarity of chronic affections as a characteristic of the pathology of western Africa, as also the severity of many acute diseases. Another point to which he calls attention is that comparatively immune subjects frequently harbor the parasites of malaria. Any affection befalling them is liable to be labeled malarial on account of the discovery of the parasite, when, in reality, it has nothing to do with malaria. Beri-beri is peculiarly severe in Kamerun. In conclusion, Plehn appends a detailed bibliography on the subject. It includes 347 works, with many by American authors. Scheube has recently published a similar comprehensive study of conditions on the eastern coast.

120. **Case of Lacking Cerebellum.**—The cerebellum had evidently developed, but had been entirely destroyed before birth by some pathologic process, probably a softening. The cerebellar tracts in the spinal cord were also lacking. On the other hand, the cortex of the cerebrum had developed apparently to compensate the missing organ. This hyperplasia of the cortex showed normal structure throughout, and the absence of any local resistance to its growth probably contributed to its unusual development. The subject was a girl in her seventh year, the ninth child of a small, slender woman of 42. Birth was normal, but it was soon noticed that the child swallowed with difficulty and frequently choked. Her death was due to suffocation from this cause. Speech and locomotion developed much slower than in other children. Even at the age of 6 she was still unable to stand or walk alone, *although the capacity for movements* had progressively improved. She understood what was said to her, but did not try to talk or move about much herself. It was difficult for her to maintain her balance alone, and almost impossible for her to bend forward or backward. The general physical development corresponded to that of a child of 3. In comparison with the disturbances in locomotion noted with even minor injuries of the cerebellum, the disturbances here were remarkably slight. The excessive development of the centripetal and centrifugal tracts for the cerebral motor impulses indicated hyperfunction and substitution, and confirms the principle of self-regulation as a law for the complicated microcosmos of

the brain, as well as for the most minute living unicellular being. The brain findings are illustrated and described in detail.

122. **Taxis in Incarcerated Hernia.**—Haberer does not allow in his clinic but one single attempt to reduce the hernia. It must be attempted very cautiously, the subject reclining in a bath. If an attempt at taxis has been made outside, before the patient reaches the clinic, no further effort is wasted, but operation is undertaken at once.

126. **Differentiation of Cholera Vibrio.**—Kraus announces that the cholera vibrio does not produce hemolysins, while all the other allied vibriones do produce them.

127. **Pseudo-Diphtheria Bacilli.**—Schwoner separates these bacilli into two groups; one includes the Hofmann bacillus and the other the xerosis and Pfeiffer urethra bacilli.

130. **Bacterio-Hemolysins.**—Volk and Lipschütz have established the existence of what they call lysinoids, the result of the decomposition of lysins, partaking of the nature of a toxoid or avirulent toxin. They announce that it is possible to induce effectual immunization with these toxoids.

132. **Cryoscopy and Reflex Polyuria.**—Catheterization of the ureters is liable to cause a reflex disturbance in the secretion of the kidneys, increasing or diminishing it. When polyuria occurs it reduces the molecular concentration of the urine from the kidney in question, and this might lead to erroneous conclusions, as it simulates an insufficiency of the kidney which may not exist in fact.

133. **Catheterization of the Ureters and Functional Diagnosis.**—Kapsammer extols the value of prophylactic instillation of a 1 or 2 per cent. solution of silver nitrate or of 1 per 1,000 bichlorid when catheterizing the ureter, to prevent infection of the upper urinary ways. In 400 catheterizations he has never found a case in which the subjects were conscious of the instillations. The parts are not so sensitive as some suppose. He also announces that the assumption that the kidneys work equally and alternately is erroneous. In 21 subjects examined, the amounts from each kidney were equal in only 4. In all the others there was a difference up to a maximum of 6 c.c. in ten minutes. His experiences in extensive experimental research were also similar in this respect. In 118 separate tests one kidney always secreted more urine than its mate, with but a single exception. In 11 tests with methylene blue elimination through the kidneys commenced simultaneously in only 4. Normal kidneys in man and animals, therefore, secrete unequal amounts of unlike urine during a given period of time. The filtering capacity of the kidneys and their eliminating capacity by no means necessarily parallel each other. As a rule, they do not work alternately, and one kidney secretes more than the other. The larger outflow of urine may keep one ureter so well washed out that there is no chance for ascending infection, which is liable to occur through the other insufficiently irrigated ureter. This explains the frequency of unilateral pyelitis. In 25 cases of pyelitis he found it bilateral in only 5.

134. **Perforated Celluloid Substitutes for Bone and Cartilage.**—Föderl, describes somes cases to illustrate the superior advantages for prothesis of a sheet of celluloid, closely perforated. He has used it to reconstruct the nose, the trachea and the jaw, and also in wounds of the skull. The flexibility of the celluloid, its smooth surface and the opportunity afforded by the perforations for the proliferation of new tissue in and through the holes, render it an ideal substance for the purpose. For the nose he used a sheet about .5 mm. thick, for the jaw much thicker. It heals in place without any reaction on the part of the tissues.

137. **New Eye Reflex.**—Wagner has found that slight pressure on the eyeball through the closed lid causes twitching of the zygomaticus and quadratus labii sup. This reflex was bilateral in 50 out of a 100 subjects, and was exaggerated in 2 cases of tetany.

138. **Rhodan in Syphilis.**—Pauli and Jungmann have observed marked improvement of the headaches in syphilitics after administration of sodium rhodanate in 2 gm. daily doses.

139. **Improved Technic of Sputum Examination.**—Sorgo breaks up the sputum with hydrogen dioxid and alcohol and then centrifugates. The sediment is not examined, but the supernatant fluid is decanted, mixed with equal parts of lime water and centrifugated again. This sediment is then examined for bacilli as usual. By this double sedimentation a much larger proportion of bacilli is saved for the microscope and they are preserved in better shape than by other methods. He describes the technic in detail, as also its application to other sedimentation procedures.

140. **Epigastric Hernia.**—Friedrich noted this form of hernia in 52 out of 12,724 men applying to the Budapest sickness insurance clinic for various reasons, and in 2 out of 2,557 women. He advocates immediate operation as soon as the hernia is discovered, except when it causes absolutely no disturbances and the subject is leading a sedentary life.

141. **Primary Endothelioma of Pleura.**—Unger's diagnosis of this lesion was confirmed by the necropsy. It was based on the pains in the right thorax developing gradually in a woman of 59 previously healthy, accompanied later by tormenting cough and dyspnea. The pains became intolerable at times and then subsided, leaving free intervals. There were no night sweats, no fever and no expectoration, but the patient lost weight and strength. During inspiration the intercostal spaces did not bulge out, and percussion showed absolute dullness over almost the entire side of the thorax. There was remarkable resistance to puncture; the fluid derived was hemorrhagic, and only 100 c.c. could be obtained by aspiration.

143. **Alopecia Areata Cured by Roentgen Rays.**—Ullmann's patient was treated by two exposures of fifteen minutes each on following days, the tube a medium soft one at 15 cm. distance. The hair in the vicinity fell out and the patient lamented for three months over this artificial aggravation of his condition. At the end of this time the hair began to grow normally again, darker in color than it had previously been. The treatment had evidently stimulated both the growth and pigmentation of the hair, and this result has been permanent during the six months since.

145. **Stamping Out Malaria Along the Austrian Adriatic.**—The two Brioni islands and the town of Barbariga have been freed from malaria during the last year. Lenz describes the various points learned in these efforts, which were commenced three years ago. He has found that the Koch method of giving quinin in prophylaxis—which is so effective in the tropics—is not so reliable in the malaria of the Istria region, which is mainly tertian. The parasites are ensconced in the spleen and bone marrow, and lie latent there for long intervals. In the spleen and marrow they are not affected by quinin, and are not sources of infection for others. When sporulation occurs the parasites swarm forth into the peripheral circulation, and a relapse of the malaria is noted. During the intervals no parasites are to be found in the blood, while in tropical malaria the parasites are almost constantly in the peripheral circulation where they are accessible to the quinin. In destroying the larvæ with kerosene, his experiences showed that the higher the oil was refined the better it spread out over the surface of the water and the less was required. Water thus coated could be used for drinking purposes without detriment. It did not taste of the kerosene when the water was drawn from near the bottom of the receptacle. His experience showed that a modified Grassi-Celli method of quinin prophylaxis proved the most effectual where strict control of the subjects was impracticable. Every one suspected of chronic malaria was given 1 gm. of quinin every day for fifteen days. After this they were given, with all the rest of the populace, 0.4 gm. (about 6 grains) quinin daily until the close of the malaria season. A very small amount of quinin is sufficient to kill the parasites in the peripheral circulation. It is administered in the evening so that the maximum is circulating at the time the mosquitoes are most active. The small amounts caused no symptoms of quinin intoxication, and in sugar or chocolate-coated tablets were taken readily, even by children. By this method, examination of the blood can be dispensed with, and none but the febrile be examined. The efforts

must be renewed each year, as infected mosquitoes can easily be brought in on beasts of burden, etc. The water tanks, etc., must be oil-coated every eighth day, and the populace inhabiting the outlying, intermediate zones must be quinin-protected as before. As the protected area enlarges, this outlying border will be removed farther and farther from the center in which malaria has been radically stamped out.

147. Stab Wounds of the Thorax.—In one of Roldan's two cases a stab in the third interspace in the back had opened a large bronchus. There was considerable hemorrhage from the vessels accompanying the bronchus. The wound in the latter was large enough to admit the little finger. To prevent hemo- and pneumo-thorax, he tamponed the depths of the wound and fastened the pleura surrounding the wound to the lips of the incision. The wound healed in two months. In a second case the knife had injured the pericardium and entered the diaphragm, but the hole in the latter was too small to fear injury of viscera below. The wound in the pericardium was not sutured, but merely drained with a small gauze wick, as at the touch of the fingers the heart action became much accelerated. The pleural cavity was packed with gauze, the skin sutured, and a compressing bandage applied. The patient was dismissed cured three months after his injury. Roldan discusses the literature on the subject of stab wounds of the pericardium, etc., and gives cuts of the after-appearance of his two patients, both mulattoes.

148. Progressive Epilepsy.—In the case described by Mestre the patient was a youth of 17, previously healthy. A few months before entering the hospital he had commenced to exhibit epileptiform seizures, gradually growing more and more severe and frequent, the spasms involving various limbs, not always simultaneously, but finally becoming practically generalized. The seizures grew more and more frequent during the last five days, with unconsciousness and death. The necropsy showed lesions in the zone of Rolando, pin-head, gray granulations along the vessels, surrounded with a gelatiniform exudate, on the ascending frontal and parietal convolutions, most numerous on the left side. The paracentral lobule was intact, as also all the rest of the cortex, except for indications of hyperemia.

151. Complications of Suppurative Otitis.—Finlay emphasizes that a patient with a suppurating otitis is like a man smoking in a powder magazine. If the affection does not yield to persevering treatment during a month or so, no time should be lost in opening an outward route for the pus. He enumerates 18 different routes by which secretions in the middle ear may escape, including in the list the veins of the dura mater, the temporomaxillary veins, the round and oval fenestræ, etc. He has performed a prophylactic mastoid operation in 24 cases with the rapid recovery of the patients, while in 7 cases in which complications had already developed, the radical operation was able to save only one patient.

152. Roldan's Method of Treating Hydrocele.—Nine engravings accompany this article, showing the various steps of the intervention with which Roldan cures hydrocele vaginalis without recurrence. The patient's pelvis is slightly raised on a cushion to allow a vessel to be placed to receive the escaping fluid. The canula is introduced until it touches the opposite wall of the hydrocele, the guide drawn down inside. The latter is then removed and the fluid allowed to escape. The canula is left undisturbed in the cavity, and the outer end is attached to a rubber tube about 30 cm. long, which communicates with a graduated glass jar, with a capacity of about 150 gm., containing a solution of bichlorid or tincture of iodin. By raising the jar, the fluid flows down into the cavity of the hydrocele, but flows out again when the jar is lowered below the level of the table, the siphon action ensuring the evacuation of all the fluid after its mission is completed. He always injects first about 40 to 60 gm. of a 2 per cent. solution of cocain, siphoning it out afterward by the same method of raising and lowering the jar, following immediately with iodin, leaving the latter in the cavity for three or four minutes, and then rinsing out the last traces of it. During all these procedures the support of the surgeon's left hand must not be removed from underneath the scrotum.

153. Tuberous Sclerosis with Kidney Lesions.—Jacobeus mentions that multiple kidney tumors are noted as accompanying the tuberous sclerosis in 7 of the 25 cases on record. The brain findings in the case described are illustrated.

154. Angiospastic Pseudo-Anemia.—Vermehren's work is based on 10 absolutely typical cases, and a number of others less definite in their type. He has also encountered a number of cases in which the anemia stage of the neurosis had not been reached. A feeling of depression and weakness is a constant symptom in the typical cases. The working capacity is slight, and the subjects feel drowsy all the time, and occasionally have headache and vertigo. Transient amnesia is also noticed at times, with chilliness, short breathing and rapid heart action, with a tendency to palpitations under emotions. Another frequent symptom is the variability of the diuresis, the urine at times scanty and dark-colored, and again copious and limpid. The subjects are usually very pale. This clinical picture is constant, but other symptoms are liable to be superadded, among them hot flashes, the hands or feet "going to sleep," the complexion becomes livid, and these transient symptoms are followed by a depression almost amounting to collapse. In none of his cases was there actual anemia, but the condition was evidently due to abnormal vascular phenomena. Only 2 out of his 10 patients displayed any predisposition to nervousness. The age ranged from 13 to 57, and the condition had been noted from childhood or puberty, and in one case from the age of 40. He attributes it to an exaggerated excitability of the vasomotor centers. They react to the influence of cold, emotions, etc., in an abnormally intense manner. This neurosis differs from neurasthenia in several points, and is best described as angiospastic pseudo-anemia. The number of red corpuscles and proportion of hemoglobin are normal or above. In treatment, he put his patients on a milk-vegetable diet, the benefits of which were marked in nearly all the cases. Valerian displayed pronounced efficacy. In one case the patient, a girl of 17, was completely cured by a combination of valerian and potassium bromid with restriction of meat. Electricity was beneficial in some cases, but failed in others. He tried nitroglycerin in 1 case without effect. When a change of scene was possible, great benefit was derived, especially from a trip to the country. The oldest patient improved on a milk-vegetable diet for two weeks, and valerian until she felt better than for many years, she said. The condition had commenced at 40 in this case.

156. Gonorrhea.—Schlasberg believes that folliculitis is a frequent complication of gonorrheal urethritis and delays its healing. The paraurethral and preputial passages may become infected and delay the cure. The prostate may also prove a source of reinfection for the urethra. An epididymitis, on the other hand, favors the cure of urethritis and also of folliculitis. Gonorrheal inguinal adenitis may possibly have a similarly beneficial effect on the process in the urethra.

PERFORATING GASTRIC ULCER; POSTERIOR GASTRO-ENTEROSTOMY; FOWLER'S POSITION.

J. H. MUSSER, M.D., and W. W. KEEN, M.D.
PHILADELPHIA.

MEDICAL HISTORY OF THE CASE AND REMARKS BY DR. MUSSER.

I have reported with Dr. Wharton a case that was in many respects similar to this. In that case operation was done within ten hours after perforation, which accident fortunately took place while the patient was fasting, an incident corresponding to the course of the second case. In the second case the operation was done five and one-half hours after perforation. The first patient had not had solid food for twenty hours, and only a small amount of coffee eight hours before perforation. The second patient had been without solid food, and had taken only albumin water for from forty-eight to sixty hours. No opportunity to make a gastric analysis was given in the first instance, although it is presumed hyperchlorhydria was present, an extreme state of which was found in the second. Doubtless this excess of acid, unneutralized, contributed to the perforation. Accordingly, it may be well to emphasize the importance of neutralizing the acid by appropriate remedies in cases of gastric ulcer, when food that takes up the acid is not permitted. Without doubt the early operations at the time when the stomachs were empty, were important factors in saving the lives of the patients.

Another point of great interest was one of dissimilarity, but the contrast teaches an important lesson. The first patient was a muscular farmer. Rigidity of the abdominal muscles was extreme. In the second case there was great atrophy of the abdominal walls, and in consequence there was no spasm or rigidity. Hence, given the lesions likely to cause spasm under other circumstances, it will be absent with abdominal walls of the character to be described.

I should like to add that the first patient is in excellent health, no gastric symptoms having returned.

I had seen Mrs. M. during November, at the request of her husband, a physician. She was 70 years of age, and had enjoyed excellent health until one year ago. She had been treated at that time by Dr. Boardman Reed for ulcer of the stomach, characterized by *pain* and hemorrhage. When seen by me she was suffering from pain, the occasional vomiting of large amounts of fluid, the daily regurgitation of a small amount. The pain was spasmodic, referred to the pylorus and relieved by regurgitation. It was not increased by food, except when the stomach was overfull.

On physical examination, the stomach, overdistended, could be well made out, and visible peristalsis was present. The pain often was coincident with the termination of a wave of peristalsis, at the region of the pylorus.

I concluded that the patient had pyloric obstruction due to spasm. No tumor could be made out. A soft tube passed into the stomach resulted in the withdrawal of two quarts of dark, grumous, offensive material. Afterward there was a perfect relief, and for almost three weeks she was without pain or distress. A test meal (Ewald) revealed total acidity 65, free HCl 40, absence of lactic acid, presence of sarcinæ and large bacilli. The odor was butyric. Lavage was done most carefully only twice, because of the possible ulcer. It seemed that an ulcer had healed causing constriction at the pylorus, or that an active ulcer was attended by pyloric spasm. The small vomitings were due to the regurgitation—the incontinence of retention. November 17 the patient washed out her stomach herself. November 19 sudden profuse hemorrhage occurred; at least a quart was vomited, followed by collapse. Rectal feedings, sips of water and egg albumin were resorted to.

November 26, at 9:30 a. m., she was seized with sudden pain in the median line or to the right, between the xiphoid and the navel, followed by shock. I saw her within half an hour. There was pain, vomiting of mucus, but no blood, rapid pulse, tenderness, no spasm, cool extremities. She lay on the left side chiefly. The pain was considerable in the back and right shoulder. Liver dullness was present. A perforation had doubtless taken place, and an operation was advised.

Dr. Keen saw the patient at 12 m. Dr. Reed, her former attendant, joined us. Reaction had set in. Temperature, 99; pulse, 85. The patient complained of great pain and favored the left lateral dorsal position. Drs. Keen and Reed concurred in the diagnosis of perforation, and urged with me immediate operation. Dr. Keen operated at 3 p. m., five and a half hours after perforation had taken place.

SURGICAL HISTORY AND REMARKS BY DR. KEEN.

I first saw Mrs. M., a woman a little past 70 years of age, in consultation with Dr. J. H. Musser and Dr. Boardman Reed, Nov. 26, 1903, at noon. I had known the patient for a number of years. I had not seen her for three or four years and was struck with her loss of weight and emaciation. After an examination, I fully concurred in the diagnosis of perforated gastric ulcer, and three hours later the operation was done.

An incision was made to the left of the middle line on account of extensive diastasis of the recti muscles following her single pregnancy about forty-eight years ago. Only a very few muscular fibers were seen. The muscles were not only widely separated, but greatly atrophied. The entire abdominal wall was not over 1 cm. in thickness. As soon as the abdomen was opened, a little turbid, rather dark colored fluid poured out, and when the stomach was drawn out, a few flakes of lymph were found on it. In a moment the perforation was discovered. It was an aperture slightly oval, very sharply punched out, 5 mm. in its long diameter, situated precisely in the middle of the pylorus anteriorly. The whole pylorus was thickened, but not nodulated. Evidently it had been the seat of an old ulcer involving all the anterior wall. The ulcer was immediately closed by a continuous Lembert suture. The abdominal cavity was then flushed out with a large quantity of salt solution, care being taken to wash out between the diaphragm and the liver, and also down into Douglas' cul-de-sac, where a considerable amount of turbid fluid was found. The diaphragm was but little injected. The transverse colon was then turned up, a hole torn through the mesocolon, and a posterior gastro-enterostomy done by means of a Murphy button. The peritoneal cavity was then again most carefully flushed out till the fluid, as in the first instance, returned clear. A number of adhesions were found between the coils of the intestine and the anterior abdominal wall and the omentum and the abdominal wall in the lower half of the abdomen, but I did not think it wise to prolong the operation by interfering with them. She was placed in bed in Fowler's position (i. e., with head of the bed raised).

She made an uninterrupted recovery, her highest temperature being 100.4 F. On December 1, five days after the operation, her temperature reached normal. In consequence of the thinness of her abdominal wall, I kept her in bed for four weeks. She went home December 31, wearing a belt and able to walk about without trouble.

The recovery from so serious a lesion as a perforating gastric ulcer and so serious an operation as abdominal section and gastro-enterostomy in a woman past 70, is a sufficient reason, it would seem, for recording such a case. Her recovery was due, I have no question, largely, first, to the promptness with which Dr. Musser acted; and, secondly, to the fact that her stomach contained little beside albuminized water. Yet, in spite of this favorable condition of the stomach, there were a few flakes of lymph already present on the stomach. A culture was taken from the abdominal cavity as soon as it was opened, and this proved, after eight days, to be sterile. I do not know that Fowler's position influenced the recovery in this case very much, in view of the facts just stated, but it certainly, at least, did no harm.

I debated for a few moments whether I should do Finney's gastroduodenostomy by means of a horseshoe-shaped incision extending from the duodenum into the stomach. I, however, finally decided against it on account of the great thickening of the whole anterior pylorus, and because I believed it would take longer than a gastro-enterostomy by the Murphy button. For the last reason also I decided against a gastro-enterostomy with simple suture.

Up to the present time, over two months after the operation, the button has not passed, but it has not produced any trouble.

To irrigate wounds or large cavities employ solutions at or slightly above body temperature, as cold interferes with repair. —*Internat. Jour. of Surg.*

BOVINE AND HUMAN TUBERCULOSIS.*

D. E. SALMON, D.V.M.
WASHINGTON, D. C.

In the last two reports presented by this committee considerable space was devoted to the subject of tuberculosis, and particularly to that phase of it which relates to the transmission of the disease from animals to man. It was shown from a review of the facts obtained by different methods of inquiry that the clinical evidence, the evidence of statistics, and the evidence from experimental researches all favored the conclusion that animal tuberculosis was a factor in the causation of human tuberculosis, and it was held that sanitarians should advocate and enforce measures to prevent the transmission of the disease from animals to man. This question is so important and so much uncertainty has been caused by the paper presented at the British Congress on Tuberculosis by Koch, and by his subsequent address at the International Conference on Tuberculosis at Berlin, that it is deemed advisable to continue the discussion in the present report.

The fact that tubercular material from human subjects often failed to produce serious disease in cattle was observed by a number of the earlier investigators who experimented with such virus. It was the experiments and comparative studies of Theobald Smith, however, which attracted special attention to the difference in virulence shown by tubercle bacilli from human and bovine sources when inoculated on cattle. Smith also mentioned certain morphologic and cultural differences in bacilli from these two sources, and in the location and histology of the lesions in cattle produced by such bacilli. He did not conclude, however, that bovine bacilli could not produce disease in the human subject, but said: "It seems to me that, accepting the clinical evidence on hand, bovine tuberculosis may be transmitted to children when the body is overpowered by large numbers of bacilli, as in udder tuberculosis, or when certain unknown favorable conditions exist."

Koch, however, in his address at the British Congress on Tuberculosis, went far beyond this and maintained that "human tuberculosis differs from bovine, and can not be transmitted to cattle." As to the susceptibility of man to bovine tuberculosis, he said it was not yet absolutely decided, but one was "nevertheless already at liberty to say that, if such a susceptibility really exists, the infection of human beings is but a very rare occurrence." He emphasized this view in the following language: "I should estimate the extent of infection by the milk and flesh of tubercular cattle, and the butter made of their milk, as hardly greater than that of hereditary transmission, and I therefore do not deem it advisable to take any measures against it."

This conclusion was so radically different from the views of most experimenters, and so out of harmony with facts which had apparently been demonstrated by others, that it at once aroused opposition in the congress, followed by the adoption of dissenting resolutions, and led to numerous investigations in various countries. Koch's conclusions were based on his failure to produce tuberculosis in cattle and other animals by inoculating them with tubercular material of human origin, and his success in causing progressive and fatal tuberculosis in the same kinds of animals when inoculated with tubercular material of bovine origin. With such positiveness did he hold to the constant and specific difference between the human and bovine bacillus that he promulgated an experimental method of discriminating between them. Speaking of the etiology of intestinal tuberculosis in man, he said: "Hitherto nobody could decide with certainty in such a case whether the tuberculosis of the intestines was of human or of animal origin. Now we can diagnose them. All that is necessary is to cultivate in pure culture the tubercle bacilli found in the tubercular material, and to ascertain whether they belong to bovine tuberculosis by inoculating cattle with them. For this purpose I recommend subcutaneous injection, which yields quite specially characteristic and convincing results."

---

* Report of the Committee on Animal Diseases and Animal Food, presented by the chairman at the meeting of the American Public Health Association, at Washington, D. C., Oct. 27, 1903.

These important and comprehensive conclusions followed from very few experiments on animals, and apparently no effort had been made to learn to what extent human tubercle bacilli might differ in their virulence for cattle or what grades of virulence there might be among bacilli of bovine origin. Vagedes had already shown that bacilli were sometimes present in human lesions which were as virulent as bovine bacilli, but his work was ignored by Koch. In the preceding report of this committee reference was made to the work of Ravenel, DeSchweinitz, Mohler, DeJong, Delépine, Orth, Stenström, Fibiger and Jensen, Max Wolff, Nocard, Arloing, Behring, and Dean and Todd, all of whom found tubercle bacilli in human lesions which proved to have about the same virulence for cattle and other animals as had the bacilli from bovine animals affected with tuberculosis. Since that report was presented Theobald Smith has reported the finding of a human bacillus virulent for cattle, and there has been made a preliminary announcement by Kossel of the results obtained by the German tuberculosis commission. The statement of Kossel should be given the most careful consideration, coming from a commission appointed on Koch's recommendation, and evidently inclined to favor his views as far as possible in its report.

Kossel stated that the commission had tested seven cultures of tuberculosis from cattle and swine, four of cattle and three of swine. Two of these cultures proved acutely fatal in cattle after 8 to 9 weeks; four of the cultures likewise produced a generalized tuberculosis, but which certainly had a more chronic course; while one of the cultures caused only an infiltration at the point of inoculation, with some caseous foci in the adjoining prescapular gland and in one of the mediastinal glands, and there was lacking the spreading of the tuberculosis over the entire body which they were accustomed to see after the injection of cultures of bovine tuberculosis. "Hence," says Kossel, "among bovine tuberculosis bacilli there can also occur differences with regard to the virulence."

The German commission also tested 39 different freshly made cultures from tuberculous disease in man. Nineteen of these cultures did not produce the slightest symptoms in cattle; with 9 others the cattle exhibited after 4 months minute foci in the prescapular glands which were mostly encapsulated and showed no inclination to progress; with 7 other cases there was somewhat more marked disease of the prescapular glands, but it did not go so far as a material spreading of the process to the glands next adjoining; there were four cultures, however, which were more virulent and caused generalized tuberculosis in the cattle inoculated with them.

It would appear, therefore, that hereafter even Koch must admit that it is impossible always to tell the source of a culture of the tubercle bacillus by its effects when it is inoculated on cattle. One of the bovine cultures failed to produce generalized tuberculosis in cattle and some of the human cultures did produce this form of the disease in such animals; moreover, while some of the human cultures caused no disease at all, others led to the development of minute foci in the prescapular glands, and still others to somewhat more marked disease of these glands. There were, consequently, four degrees of virulence noted in these 39 cultures of bacilli from human sources, and three degrees of virulence in the 7 cultures from animal sources. Now, if we accept the views of Koch as to the specific difference between human and bovine tubercle bacilli, and that the human bacilli produce only localized lesions in cattle, while bovine bacilli produce generalized lesions in these animals, must we not conclude that the one non-virulent bovine culture was in reality of human origin and that the animal from which it was obtained had been infected from man? This is a logical deduction, but reverses the dictum laid down at London that human tuberculosis is not transmissible to cattle. Again, how are we to explain the human cultures of medium virulence? Are they human bacilli which for some unknown reason are increasing in virulence and approaching the activity of the bovine bacillus, or are they really bovine bacilli which have multiplied in the human body until their virulence has become attenuated? In whatever manner these questions are decided, it would seem that the findings of the German commission, instead of supporting Koch's views that we can decide with certainty by the inoculation of cattle as to the source of any given bacillus, really show that this method of diagnosis is extremely uncertain in the present condition of our knowledge.

It is definitely admitted that four of the human cultures caused generalized tuberculosis in cattle; but Kossel suggests that it might be possible that the bacilli in cases of human tuberculosis under certain circumstances could likewise attain a very high pathogenic activity for cattle without being for that reason bovine bacilli. Undoubtedly, the German commission is confronting the two horns of a dilemma, either one of which is fatal to the views of Koch as stated with such positiveness at London. If we accept this suggestion thrown out by Kossel, we must conclude that Koch was wrong in his assertion that human tuberculosis can not be transmitted to cattle, and thus with one blow we destroy the entire experimental support which he had for his argument before the British Congress on Tuberculosis. And if, on the other hand, we accept the conclusion which follows from the principle laid down by Koch for the discrimination between human and bovine bacilli, and which appears to be favored by Kossel, we must admit that bovine tuberculosis is an extremely important factor in the etiology of human tuberculosis. Of the 39 cases of human tuberculosis tested, 4, or over 10 per cent., were virulent for cattle and would be classified as of bovine origin; but these 4 cases were all found among the 16 cases of tuberculosis in children which the commission investigated; hence, it is plain that 25 per cent. of the cases tested of tuberculosis in children would by Koch's method be classified as of bovine origin.

In the Bureau of Animal Industry two distinct lines of experiments have been carried on, in order that one might serve as a check against the other. There has been, however, no discrepancy in the results. De Schweinitz, in the biochemic division, has isolated nine cultures from human tuberculosis. Two of these were derived from human sputum, three from cases of generalized tuberculosis in adults, and four from cases of generalized tuberculosis in children. By comparing these cultures with a newly isolated virulent culture of bovine tuberculosis, there were found among them two cultures from children which were identical in their cultural and morphological characters with the bovine bacillus. These cultures also killed rabbits and guinea-pigs in as short a time as did the bovine bacillus. Hogs which were inoculated subcutaneously with these two cultures from children died of generalized tuberculosis. Two calves, weighing over 30 pounds each, were inoculated subcutaneously with these virulent human cultures *and as a result developed generalized tuberculosis.* A yearling heifer inoculated with one of the cultures showed generalized tuberculosis when killed three months after inoculation. Both the cattle and the hogs had been tested with tuberculin and found to be free from tuberculosis before the inoculations were made. It is important to observe in this connection that two out of four, or 50 per cent. of the cultures obtained from cases of generalized tuberculosis in children, proved virulent for cattle.

Mohler, working in the pathological division, has obtained three very virulent cultures of tubercle bacilli from the human subject. A goat inoculated subcutaneously with one of these cultures died in 37 days with miliary tuberculosis of the lungs involving the axillary and prescapular glands. This bacillus was obtained from the mesenteric gland of a boy. Of still greater interest is a bacillus isolated by Mohler from human sputum. A goat inoculated subcutaneously with a culture of this germ died in 95 days of pulmonary tuberculosis. A cat inoculated in the same manner died in 23 days of generalized tuberculosis. A rabbit similarly inoculated died in 59 days of pulmonary tuberculosis. Another rabbit inoculated with a bovine culture for comparison lived 10 days longer than the one inoculated with this sputum germ. Mohler also inoculated subcutaneously a 1-year-old heifer with a culture derived from the tubercular mesenteric gland of a boy 4 years of age. This culture was always refractory in its growth under artificial conditions, and the bacilli were short stubby rods corresponding in appearance with the bovine type. At the autopsy, held 127 days after the inoculation, the general condition was seen to be poor and unthrifty, and large, hard tumors were found at the points of inoculation. On the right side, the swelling measured 3½ by 5 inches, and the corresponding lymph gland was 2¾ inches long by 1¾ inches in diameter. This gland contained numerous calcareous foci, one of these at the apex being an inch in diameter. The lesions on the left shoulder of the animal were very similar to those found on the right side, but the dimensions of the tumor were slightly less. The lungs presented an irregular mass of tubercular nodules, and 7 or 8 grape-like nodules were seen on the parietal pleura. Bronchial and mediastinal lymph glands contained numerous tubercular foci, and the pericardium, peritoneum, spleen and liver were also affected.

In order to throw some light, if possible, on the morphological constancy of the different types of tubercle bacilli, Mohler was requested by the chairman of your committee to make comparative studies of bacilli from various sources, and which had been passed through various species of animals, by making the cultures on dog serum after the method described by Theobald Smith. Some important results have been obtained. One culture of human bacilli which had morphological and cultural peculiarities similar to those of the bovine bacillus, and which only produced local lesions in cattle, was passed through a series of 5 cats. It was then found to be completely changed in its morphological characters, the rods being elongated, slender, more or less beaded and entirely of the human type. But far from decreasing in virulence, as might be expected from their morphological appearance, this bacillus had so increased in its pathogenic activity that it now produced generalized tuberculosis in a cow. This cow was inoculated subcutaneously in front of each shoulder with 2 c.c. of a salt solution emulsion of the tuberculous omentum of the last cat of the series. The cow rapidly lost flesh, had a temperatore of 104° F., with the point of inoculation and adjacent glands greatly swollen. The autopsy revealed generalized tuberculosis, involving the lungs, mediastinal glands, spleen, liver and kidneys. Tubercle bacilli of the bovine type obtained from the mesenteric glands of a sheep, hog and cow were similarly transformed in their morphological appearance after being passed through a series of cats and recovered on dog serum. These bacilli also increased in virulence, as the last cat of the series invariably succumbed in a shorter time than the first of the series.

These experiments and observations indicate that the types of tubercle bacilli are very inconstant, and that under suitable conditions they readily change both in morphology and in virulence. A similar conclusion was reached by other investigators in working with the avian and piscine types of tubercle bacilli several years ago, and was reasonably to have been expected with the human and bovine types.

It must be plain to all from these recent developments, that too much has been made of the slight differences in cultural characteristics, in morphology, and in virulence which have been observed in some cases in comparing the human and the bovine bacilli. The observations were interesting and it was important that they should be followed up until their significance was made entirely clear; but it was an almost unpardonable error, from a sanitary point of view, to promulgate sweeping generalizations, calculated to arrest and abolish important measures for preventing human tuberculosis, before the soundness of these generalizations had been established by a thorough course of experimentation.

When Koch said in the British Congress on Tuberculosis that he should estimate the extent of infection by the milk and flesh of tubercular cattle, and the butter made of their milk, as hardly greater than that of hereditary transmission, and that he therefore did not deem it advisable to take any measures against it, he went far beyond what was justified by any experiments or observations which he reported, and he did an immense amount of harm which will be manifested for years to come to those who endeavor to guard the human race from the dangers of animal tuberculosis. The researches to which your committee has alluded make these dangers more definite and certain than they have appeared before, and sanitarians should therefore most earnestly endeavor to counteract the erroneous and harmful impression which was made by Koch's address at London and his subsequent address at the International Conference on Tuberculosis at Berlin.

Now that the conclusions of the London address are shown to be incorrect and based on insufficient experimentation, it is well that some attention should be given to the Berlin address in which certain rules were laid down for testing all clinical evidence before it can be accepted as indicating the transmission of tuberculosis from animals to man. While your committee agrees that it is advisable to scrutinize clinical evidence as carefully as possible before it is accepted as influencing the decision of such an important question, consistency demands that we should accept clinical evidence bearing on the transmission of bovine tuberculosis to man on the same terms that we accept evidence bearing on the transmission of tuberculosis from man to man. For instance, Koch said in his London address, "So the only main source of the infection of tuberculosis is the sputum of consumptive patients." How does he know this? Has he any evidence to support this conclusion which will stand the requirements which he has laid down for those who oppose his views with reference to the transmission of animal tuberculosis to man? If so, this evidence has not yet been presented. Your committee believes that the principal source of tuberculosis in man is infection from other tuberculous human subjects, but it also believes that a considerable proportion of the cases of tuberculosis in man is due to infection from animal sources; and in weighing the evidence by which we are to fix more rigorously the relation which these two sources of infection bear to each other, it is logical that we should apply the same rules of evidence in each case.

The rules which Koch formulated for testing the evidence as to bovine infection are given below, with such brief comments as your committee feels they deserve.

"1. Certain proof of tubercle, and where possible the primary focus must be supplied."

To this condition no objection is raised, but it should be remarked that the location of the primary focus, which is made so much of, is of little value in determining the origin of the infection. It has been clearly shown by various investigators, whose work has been referred to in the preceding reports of this committee, that tubercle bacilli may pass through the walls of the intestine without producing any lesion at the point of entrance, and that their first point of lodgement and multiplication may be the mesenteric glands, the liver, spleen or even the lungs. On the other hand, Koch has told us that the location of the primary lesion in the intestine is of no significance because human as well as animal bacilli may be swallowed and may be the cause of such lesions. It is, therefore, not at all apparent that this is an essential point.

"2. Other sources of infection must be excluded with certainty."

This condition appears to exclude all clinical evidence bearing on the source of tubercular infection. How is it possible to prove that any given individual has not been exposed to the bacilli of human tuberculosis? And, for the same reason, how is it possible to prove that any given individual has not been exposed to the bacilli of animal tuberculosis? It may be said that this consumptive person had habitually been in a room with another consumptive patient and was infected from that patient. But how can you prove that this person never ate any tuberculous meat, never partook of any tuberculous milk, never ate any butter containing the tubercle bacillus, never had opportunity to be indirectly infected from the hands of cooks or from table utensils which had been in contact with tuberculous meat, milk, or butter, and was never exposed to the infection scattered in so many ways by tuberculous animals? It is impossible to exclude with certainty all these sources of infection, and if we apply the condition under discussion to the evidence on which Koch based the assertion that the main source of the infection of man is the sputum of consumptive patients, we would find no part of it that would stand the test. Now, is it logical to accept clinical evidence, as to the transmission of tuberculosis from man to man, by one set of rules, and to require an entirely different set of rules when considering evidence as to the transmission of the same disease from animals to man? Your committee is of the opinion that clinical evidence should be regarded as valuable in confirming experimental researches, or in indicating the probable facts where experimentation has been insufficient or is impossible, but that it is too much to expect that clinical evidence will be forthcoming as to the transmission of tuberculosis which will exclude all possible sources of error.

"3. In each case of alleged infection from milk affected with bovine tuberculosis the condition of the rest of the people who have taken the same milk should be borne in mind. These fellow consumers form to a certain extent a control experiment, and if of the numerous people who have drunk the suspected milk only a single one sickens, this weighs decidedly against the belief that this one person was infected by the common food."

This condition, also, is regarded by your committee as illogical and impossible of general application without discarding all clinical evidence on this question. If we apply it to the alleged cases of sputum infection, we find it is seldom, indeed, that the disease in more than one person can be traced with any probability to the same tuberculous patient, although scores of persons may have been exposed to that patient. Most people who escape tuberculosis have nevertheless been exposed many times to tuberculous patients, but this is not sufficient reason for concluding that others have not contracted the disease by similar exposure. Tuberculosis is a disease which is communicated with such difficulty among people under ordinary conditions of life, either by exposure to diseased persons or to tuberculous food, develops so slowly, and varies so much in the period which elapses before symptoms are observed, that it is only very rarely that groups of cases are observed which even appear to have originated from the same source. And yet, how erroneous it would be to exclude clinical evidence suggesting contagion because only one of those exposed to a certain consumptive had contracted the malady.

"4. The source of the milk should be attended to. Since in recent years it has become more and more evident that milk containing tubercle bacilli is yielded by such cows as suffer from tuberculosis of the udders, the general statement that some one has drunk milk from a cow suffering from tuberculosis no longer suffices to prove to us that bovine tuberculosis bacilli have really reached his digestive organs. It must be from a cow suffering from tuberculosis of the udder, and therefore a statement on this subject should not be wanting in a report on milk infection if it is said to be complete."

Your committee finds this statement of fact to be incorrect, since the tendency of recent investigations by competent persons is to make it more and more evident that cows with tuberculosis may yield milk containing tubercle bacilli when the udders present no signs of the disease. The argument is, therefore, antiquated. Of the many experiments that have been made to determine the proportion of tuberculous cows which yield infectious milk, the average results are about 15 per cent, while the cases of tuberculosis of the udder are about 2 per cent. In recent investigations made by Mohler of the Bureau of Animal Industry with 56 reacting cows, it was found that 12 of these, or 21.4 per cent., at one time or another during the experiment gave milk which contained virulent tubercle bacilli. Undoubtedly cows with tuberculosis of the udder yield milk containing a larger number of tuberculosis bacilli than do those in which the udder remains unaffected and are, therefore, more dangerous, but it has been clearly shown that other tuberculous cows may yield virulent milk.

So much for the conditions laid down by Koch for testing clinical evidence bearing on the transmission of tuberculosis from animals to man. The effort to rule out all such evidence by applying impossible tests does not meet with our approval, but fortunately clinical evidence is no longer necessary for deciding the question. The subcutaneous injection of cattle with pure cultures of the tuberculosis bacillus from human sources, which, according to Koch, "yields quite specially characteristic and convincing results," has proved, in the hands of the German commission no less than in those of independent investigators, that bovine tuberculosis is communicable to man. It will require much work to decide with even approximate accuracy the proportion of human tuberculosis caused by animal infection; but the fact that 25 per cent. of the cases in children investigated by the German commission, and 50 per cent. of similar cases investigated by De Schweinitz showed by this test that they were caused by animal infection, is sufficient to convince us that measures should be taken and enforced at once to guard against infection from this source.

In concluding your committee desires to express its appreciation of the prompt, intelligent and indefatigable work of those scientific investigators who took up this question immediately after it was brought to the front at London, and who, in the comparatively short period of two years, have furnished the material for definitely settling it, so far as the principal contention is concerned.

THE CONDITION OF THE BLOOD IN PATIENTS SUFFERING FROM PULMONARY TUBERCULOSIS.*

JOHN M. SWAN, M.D.
Demonstrator of Osteology, University of Pennsylvania; Pathologist, St. Mary's Hospital; Instructor in Clinical Medicine, Philadelphia Polyclinic.
PHILADELPHIA.

The study of the blood in the patients who furnished the material for this paper was made possible by the kindness of Dr. Julius L. Salinger, who placed his tuberculosis ward in the Philadelphia Hospital at my disposal. The paper is based on the counting of the erythrocytes, the counting of the leucocytes, the estimation of the hemoglobin, the differential count of the leucocytes and the search for the iodin reaction of the leucocytes in twenty-five cases of pulmonary tuberculosis, and one case of extensive cavity formation in the lung due to bronchiectasis.

In studying the results of these blood counts I shall adopt the classification of Grawitz,[1] who divides the disease into three stages. A first stage, in which there is a beginning affection of the apex, without cavity formation; a second stage, in which there are symptoms of cavity formation with slight fever or without fever; and a third stage in which hectic fever is present.

FIRST STAGE.

There is one patient (26) who represents the first stage of consolidation of the apex, without cavity formation. This patient showed a slight reduction of the erythrocytes to 3,980,000; a normal number of leucocytes, 10,000; and a moderate reduction of hemoglobin to 70 per cent. This patient improved very much under treatment, and was finally discharged without symptoms and with few physical signs. As his general condition improved there was a corresponding improvement in the blood picture; the erythrocytes rose to 4,580,000 and the hemoglobin increased to 82 per cent. With the improvement of the blood condition, the leucocytes rose to 16,600.

An examination of the differential leucocyte count of this patient shows that the relative proportion of the different cells was not changed. The treatment, under which the patient greatly improved, apparently caused an increase in the eosinophiles from 1.6 to 3 per cent.

SECOND STAGE.

There are eight patients (2, 4, 5, 6, 10, 14, 20, 22) representing the second stage of the disease. In these cases the erythrocytes were usually normal in number. In four instances they were present in greater numbers than 5,000,000 to the cubic millimeter, and in one instance they only numbered 3,680,000. The range of the erythrocyte counts was from 6,710,000, in a negro who had complained of cough for twelve years, to 3,680,000, also in a negro, who had been ill for two and one-half months, and who had albuminuria.

Seven of these patients showed a leucocytosis, varying from 34,000 to 11,120, and one showed a leucopenia of 7,100. The latter patient had carried a cavity in his right lung for a number of years and the disease was stationary.

In these patients the differential counts showed, as a rule, a percentage of polymorphonuclear cells above 80, the highest being 93.4. In three cases the polymorphonuclears formed 70.4 per cent., 73.6 per cent., and 78.8 per cent of the leucocytes, respectively. In one patient the first examination was made during an asthmatic paroxysm and showed 80.8 per cent of polymorphonuclear cells. A second examination was made about four weeks later, after the asthmatic paroxysms had ceased, and gave 78 per cent. of polymorphonuclear cells. Eosinophile cells were present in all of these patients except two, in proportions varying from 3 per cent. to 0.2 per cent. The two patients from whose blood these cells were absent left the hospital before a second examination could be made and their ultimate fate is unknown.

The hemoglobin varied from 90 per cent to 63 per per cent., although all patients showed some pallor of the skin and the mucous membranes. Indeed, in some instances the percentage of hemoglobin was at first thought to have been erroneously estimated until more than one trial showed the reading to be accurate.

THIRD STAGE.

There are fifteen patients (3, 7, 8, 9, 11, 12, 13, 15, 16, 17, 18, 19, 21, 23, 25) who may be placed in the third stage of the disease—that of hectic fever. In these patients the erythrocytes were usually reduced in number, although a normal number of these cells was occasionally found. The counts ranged from 5,710,000 to 2,890,000, with an average of about 4,019,130. The highest count was obtained from a patient who was rapidly improving under treatment; indeed, he might be placed in the second stage of the disease but for the fact that a former count was made while he was having marked hectic fever. The leucocytes were usually increased in number, giving a leucocytosis of from 247,000 in a very rapidly progressing case, to 10,080. Five patients gave a leucocyte count below 10,000; 8,480, 7,600. 7,600 to 9,600, and 6,733, respectively. The polymorphonuclear cells were usually above 80 per cent., varying from 97.6 per cent. to 80 per cent. In five instances these cells formed less than 80 per cent of the entire number of the leucocytes, varying from 78.8 per cent. to 69 per cent. The eosinophile cells were usually absent from the blood of those cases that proved fatal. The hemoglobin varied from 95 per cent. in a patient who was improving on treatment, to 35 per cent. A rise in the hemoglobin percentage was usually noted just before death, and was attributed to the sluggishness of the peripheral circulation as the end approached.

---

* Read before the Philadelphia County Medical Society.

[1] E. Grawitz: Deutsche med. Woch., 1893, No. 51, p. 1374.

In the case of a patient who failed rapidly and who died about forty-three days after admission, the erythrocytes numbered 3,800,000, 3,820,000, 3,020,000, and the day before death, 4,600,000. In this patient the leucocytes were always below 10,000; 7,600, 7,000, 6,300, rising the day before death to 9,600. The hemoglobin varied from 50 per cent., 55 per cent., 55 per cent. to 85 per cent. the day before death. The percentage of polymorphonuclear cells was 77.2 per cent., 80 per cent., 78.8 per cent. and 80 per cent., respectively. When the blood was first counted, there was 0.4 per cent. of eosinophiles, but twenty-four days later these elements had disappeared and were not again found in the peripheral blood.

COMPLICATIONS.

The series of cases comprising this study contains two cases of pulmonary hemorrhage, six cases of albuminuria, two cases of tuberculous diarrhea, five cases of pleurisy and one case of asthma.

HEMORRHAGE.

One patient (11) had been spitting blood for two weeks and had had two distinct hemorrhages, the last one a few days before the blood examination was made. The hemoglobin suffered a marked reduction (55 per cent.); the erythrocytes numbered 5,220,000; there was no leucocytosis (8,480). There were no nucleated erythrocytes, and the differential count showed nothing abnormal.

The second patient (23) had two hemorrhages on May 25. May 28 his hemoglobin was 55 per cent.; there was a leucocytosis of 15,800, but the erythrocytes numbered 4,380,000. The lymphocytes were reduced to 7 per cent., and there were 14.4 per cent. of transitional forms. The man had a third hemorrhage on May 30, and two days later the erythrocytes numbered 3,430,000, there was a leucocytosis of 20,700, and the hemoglobin was reduced to 55 per cent. There were no nucleated erythrocytes.

ALBUMINURIA.

Albuminuria seems to have little if any influence on the blood picture. Of the six cases (3, 10, 13, 16, 18, 20) in which this complication was noted, the erythrocytes varied from 6,710,000 to 2,890,000. The leucocytes varied from 24,240 to 7,600. The hemoglobin varied from 37 per cent. to 90 per cent. The polymorphonuclear cells formed more than 80 per cent. of the total number of leucocytes except in two instances. Eosinophile cells were absent from the peripheral blood in all except two instances.

TUBERCULOUS DIARRHEA.

Two patients (3 and 9) suffered from tuberculous diarrhea. In both of these patients the erythrocytes were reduced and the leucocytes were increased in number; the hemoglobin was markedly reduced and the polymorphonuclear cells formed more than 80 per cent. of the total number of leucocytes.

PLEURISY.

Of the five cases (3, 12, 16, 22, 25) of pleurisy, the most constant feature of the blood examination was the leucocytosis. One patient (16) did not show the reaction, his leucocytes only numbering 8,100. In the others the leucocytes varied from 10,600 to 34,000. The polymorphonuclear cells constituted the bulk of the leucocytes in these cases.

Case 24 presented non-tuberculous cavities in the posterior portions of both lungs. This patient's blood count was as follows: erythrocytes, 4,750,000; leucocytes, 15,400; hemoglobin, 70 per cent. The polymorphonuclear cells formed 81.2 per cent. of the leucocytes and there were 1.8 per cent. eosinophiles.

IODOPHILIA.

I did not succeed in demonstrating the iodin reaction in any of my specimens. Locke[2] has found this reaction absent in uncomplicated tuberculosis, but DaCosta[3] has found it present in septic cases.

EOSINOPHILIA.

As the study progressed, my attention was attracted by the fact that eosinophile cells were not to be found in many of the specimens, and it soon became apparent that the cases in which these cells were absent were fatal ones. There are five exceptions to this, however. Case 9 at the time of examination showed 0.4 per cent. of eosinophiles and he is known to have died, although how long after the examination I am unable to say. Case 12 showed 0.8 per cent. eosinophiles four weeks before death; but when a second examination was made, two weeks before death, no eosinophile cells were present. Case 17 showed 0.4 per cent. eosinophiles forty-two days before death, but examinations made seventeen, six and one day before death showed absence of eosinophiles. Case 24 showed 1.8 per cent. eosinophile cells, and the patient died after a surgical operation for the drainage of non-tuberculous pulmonary cavities.

Cases 6, 7 and 10 showed absence of eosinophiles when the blood was examined, but these patients left the hospital and their fate is unknown.

Cases 25 and 26 were under treatment, which apparently produced much improvement in the physical conditions of the patients. In these patients the eosinophiles increased as improvement progressed; in 25 rising from 0.2 on the first examination to 1.6 per cent. on the second; in 26 rising from 1.6 per cent. to 3 per cent.

I am inclined to believe that the presence or absence of eosinophiles in the peripheral blood of tuberculous patients, is a sign of some prognostic significance. Levaditi[4] makes the following statement: "Tuberculin, among the bacterial products, appears to have eosinophilous properties. Jürgens has already shown in tuberculous patients who succumbed in the course of treatment with tuberculin, an increase of the number of white cells of the blood. Tschistowitch, Grawitz, Bischoff and Botkin examined the blood during life and discovered quantities of eosinophiles much above normal. This oxyphilia appeared also, according to the more recent statements of Bettman, in the course of the treatment of tuberculosis with tuberculin and with cinnamic acid." Zappert[5] also found an increase of eosinophile cells after injections of tuberculin; but in four out of eight cases of pulmonary tuberculosis these cells were reduced in number, and in another of the eight cases they were absent. There is no note as to the ultimate fate of these five patients.

[4] C. Levaditi: Le Leucocyte et ses Granulations, Paris, October, 1902, p. 117.

Claude and Aly-Zaky[6] say that treatment of experimental tuberculosis in guinea-pigs produced changes in the blood formula as seen in control animals. In those animals in which treatment has resulted in deferring the fatal termination, the eosinophiles have been found increased, even as high as 12 per cent. in some cases, particularly in the period of initial reaction to the infection.

Cabot[7] says that in most cases associated with leucocytosis, eosinophiles are absent. They may be increased in cases with cavities in which possibly the individual inoculates himself with tuberculin manufactured in the cavities of his own lungs.

Brown[8] quotes Teichmüller's statement that an increase of the eosinophiles in the blood and in the sputum of tuberculous patients is a favorable prognostic sign. Brown himself agrees with the observation of Teichmüller that the percentage or absolute number of eosinophile cells present is of real value in the prognosis of tuberculosis. Teichmüller's[9] work was done on sputum which he stained by various methods, principally by eosin and methyl blue. He believes that in bad cases eosinophile cells are usually absent from the sputum, although an isolated cell may be found occasionally. He considers the study of the eosinophile cells in sputum an indispensable aid. It gives a method of estimating the resisting power of the patient, of determining the prognosis and of critically estimating the value of special therapy.

Ehrlich and Lazarus[10] account for the occurrence of a polymorphonuclear leucocytosis by the chemotactic influence of certain bacterial products. The neutrophile cells are the ones ordinarily drawn from their storehouse in the bone marrow by this chemotactic influence of substances circulating in the blood stream.

The majority of the bacterial products are positively chemotactic for the neutrophile cells, while only a few substances, among which tuberculin is included, according to the observations of the authors just quoted, are positively chemotactic for the eosinophile cells. The variation of the eosinophile cells in the circulating blood of tuberculous patients may be explained as follows: In cases of incipient tuberculosis eosinophile cells are present in the blood stream in about normal proportion, because there is not enough tuberculin manufactured in the lesions to produce a marked eosinophilia. When, however, the secondary infection with the organisms of suppuration occurs, the neutrophile cells are attracted by the chemotactic power of the products of their growth which circulate in the blood and the eosinophile cells are repelled, so that we find an excess of polymorphonuclear neutrophile cells in the peripheral blood. As the patient gradually becomes more saturated with the latter poisons and the fatal termination approaches, the eosinophiles progressively diminish in number and disappear from the peripheral blood. If, however, the progress of the case is influenced favorably by treatment, the symptoms of the secondary infection disappear and the chemotactic influence of the products of the pyogenic organisms is withdrawn, so that the tuberculin being produced in the lesions may exercise its chemotactic influence to attract the eosinophilous polymorphonuclear cells from the bone marrow into the blood stream.[11]

A summary of the cases follows:

Case 1.—W. T., aged 49 years, negro. March 3, 1902, 3:30 p. m.: Patient comatose, temperature 101.6. Erythrocytes, 4,437,500; leucocytes, 4,900; ratio, 1-905; hemoglobin, 95 per cent. Differential count, polymorphonuclears, 72.4 per cent.; lymphocytes, 16 per cent.; transitionals, 11.6 per cent.; eosinophiles, 0.0 per cent. Iodin reaction negative. Patient died two and a half hours after making blood examination.

Case 2.—C. K., aged 48 years, white. March 5, 1902, 3 p. m.: Temperature 98.4 per cent. Erythrocytes, 5,890,000; leucocytes, 16,160; ratio, 1-364; hemoglobin, 90 per cent. Differential count, polymorphonuclears, 78.8 per cent.; lymphocytes, 12.2 per cent.; transitionals, 7.8 per cent.; eosinophiles, 1.2 per cent. Iodin reaction negative. Discharged from hospital.

Case 3.—T. B., aged 46 years, white. History: Cough and expectoration for eight months. Diarrhea for seven weeks. Nine stools a day. Cavity at right apex. Right lung completely consolidated. Pleuritis extensive. Left lung many areas of consolidation. Appearance anemic. Much emaciated. Heart displaced to right by adhesions. Urine contained albumin and hyaline casts. March 17, 1902: Sputum contained tubercle bacilli, diplococci, streptococci, pus cells, alveolar epithelium. March 5, 1902, 4 p. m.: Temperature 102. Erythrocytes, 2,890,000; leucocytes, 24,240; ratio, 1-118; hemoglobin, 53 per cent. Differential count, polymorphonuclears, 88.8 per cent.; lymphocytes, 4 per cent.; transitionals, 7.2 per cent; eosinophiles, 0.0 per cent. Iodin reaction negative. March 14, 1902, 3:30 p. m.: Temperature 100. Erythrocytes, 3,200,000; leucocytes, 20,240; ratio, 1-158; hemoglobin, 37 per cent. Differential count, polymorphonuclears, 87.2 per cent.; lymphocytes, 6.6 per cent.; transitionals, 6.2 per cent.; eosinophiles, 0.0 per cent. Iodin reaction negative. Died March 20, 1902.

Case 4.—E. M., aged 72 years, white. History: Patient has been in the tuberculosis ward for a long time. Has a very slow tuberculous process. March 10, 1902, 2:30 p. m.: Temperature, 98. Erythrocytes, 5,260,000; leucocytes, 14,800; ratio, 1-355; hemoglobin, 90 per cent. Differential count, polymorphonuclears, 80.4 per cent.; lymphocytes, 8 per cent.; transitionals, 10.4 per cent.; eosinophiles, 1.2 per cent. Iodin reaction negative. May 8, 1902: Erythrocytes, 4,720,000; leucocytes, 11,500; ratio, 1-410; hemoglobin, 85 per cent. Differential count, polymorphonuclears, 77 per cent.; lymphocytes, 17 per cent.; transitionals, 3 per cent.; eosinophiles, 3 per cent. Iodin reaction negative.

Case 5.—B. McS., aged 42 years, white. History: Patient has been in the wards of the Philadelphia Hospital several times. Has frequent asthmatic paroxysms. March 10, 1902, 3:30 p. m.: Temperature 98.4 during an asthmatic paroxysm. Erythrocytes, 4,520,000; leucocytes, 29,760; ratio, 1-151; hemoglobin, 83 per cent. Differential count, polymorphonuclears, 80.8 per cent.; lymphocytes, 13.6 per cent.; transitionals, 2.6 per cent.; eosinophiles, 3 per cent. Iodin reaction negative. April 14, 1902, 3:30 p. m.: Patient recovered from his asthmatic attacks, is out of bed every day, and goes out into the yard.

Coles: The Blood; How to Examine and Diagnose Its Diseases, London, 1902. Rud. R. v. Limbeck: The Clinical Pathology of the Blood; English Translation by Arthur Latham and John Nachbar, New Sydenham Society, 1901. H. Strauss and R. Rohnstein: Die Blutzusammensetzung bei den verschiedenen Anäm., Berlin, 1901.

Temperature, 99; pulse, 92; respiration, 22. Erythrocytes, 4,610,000; leucocytes, 14,500; ratio, 1-318; hemoglobin, 80 per cent. Differential count, polymorphonuclears, 78 per cent.; lymphocytes, 12.4 per cent.; transitionals, 8.6 per cent.; eosinophiles, 1 per cent. Iodin reaction negative. Patient was finally discharged improved and was readmitted during the winter of 1902-03 for the same condition.

Case 6.—G. S., aged 41 years, white. History: Cavity formation. March 10, 1902, 4:30 p. m.: Temperature 99.8. Erythrocytes, 4,210,000; leucocytes, 11,120; ratio, 1-378; hemoglobin, 63 per cent. Differential count, polymorphonuclears, 80.2 per cent.; lymphocytes, 10.2 per cent.; transitionals, 9.6 per cent.; eosinophiles, 0 per cent. Iodin reaction negative. Patient refused to remain in the hospital.

Case 7.—H. T., aged 32 years, black. History: Cavity formation at right apex. March 12, 1902, 3:15 p.m.: Temperature 100.4. Erythrocytes, 3,730,000; leucocytes, 10,080; ratio, 1-370; hemoglobin, 35 per cent. Differential count, polymorphonuclears, 89.2 per cent.; lymphocytes, 6.6 per cent.; transitionals, 4.2 per cent.; eosinophiles, 0 per cent. Iodin reaction negative. Patient left the hospital of his own accord.

Case 8.—W. M. G., aged 47 years, white. History: Cavity formation both apices. March 12, 1902, 4:00 p. m.: Temperature, 100.2. Erythrocytes, 3,580,000; leucocytes, 20,240; ratio, 1-176; hemoglobin, 35 per cent. Differential count, polymorphonuclears, 76 per cent.; lymphocytes, 18 per cent.; transitionals, 5 per cent.; eosinophiles, 1 per cent. Iodin reaction negative. Patient subsequently left the hospital.

Case 9.—W. B., aged 34 years, white. History: Patient has been sick for 14 months complaining of cough, night sweats, loss of flesh and diarrhea. Six stools daily. Much expectoration. Consolidation of both apices with cavity formation. March 19, 1902: Sputum shows tubercle bacilli, cocci, alveolar epithelium and pus cells. 2:30 p. m., temperature 101. Erythrocytes, 4,240,000; leucocytes, 13,440; ratio, 1-315; hemoglobin, 42 per cent. Differential count, polymorphonuclears, 88.8 per cent.; lymphocytes, 6 per cent.; transitionals, 4.8 per cent.; eosinophiles, 0.4 per cent. Iodin reaction negative. Patient died.

Case 10.—W. T., aged 30 years, black. History: Patient has been sick 2½ months suffering from dyspnea, cough and expectoration. Consolidation of both apices. Albuminuria. History of chills and fever 2½ years ago. March 19, 1902, 3:30 p. m.: Temperature 97.8. Erythrocytes, 3,680,000; leucocytes, 23,760; ratio, 1-154; hemoglobin, 90 per cent. Differential count, polymorphonuclears, 85.4 per cent.; lymphocytes, 10.8 per cent.; transitionals, 3.8 per cent.; eosinophiles, 0 per cent. Iodin reaction negative. Patient left hospital.

Case 11.—D. W., aged 20 years, black. History: Complains of cough and expectoration of 4 months' duration with paroxysmal diarrhea and night sweats. Two weeks ago began to spit up blood, and has had 2 distinct hemorrhages. No chest pain. Consolidation at right apex. March 21, 1902. Sputum examination shows tubercle bacilli, pus cells and few cocci. 2:30 p. m., temperature 100. Erythrocytes, 5,220,000; leucocytes, 8,480; ratio, 1-615; hemoglobin, 55 per cent. Differential count, polymorphonuclears, 73.2 per cent.; lymphocytes, 20.4 per cent.; transitionals, 5.4 per cent.; eosinophiles, 1 per cent. Iodin reaction negative. Patient discharged improved.

Case 12.—R. C., aged 23 years, white. History: Influenza in February, 1902; this was followed by night sweats, cough at night and expectoration. Consolidation at right apex, no cavity. March 28, 1902: Sputum showed tubercle bacilli. 3:30 p. m., temperature, 99; pulse, 130; respiration, 26. Erythrocytes, 4,600,000; leucocytes, 20,480; ratio, 1-224; hemoglobin, 57 per cent. Differential count, polymorphonuclears, 85.2 per cent.; lymphocytes, 8.4 per cent.; transitionals, 5.6 per cent.; eosinophiles, 0.8 per cent. Iodin reaction negative. April 7, 1902, 3:00 p. m.: Temperature, 98.4; pulse, 124; respiration, 24. Consolidation of right apex; no cavity could be made out. Erythrocytes, 4,140,000; leucocytes, 25,600; ratio, 1-161; hemoglobin, 56 per cent. Differential count, polymorphonuclears, 91.8 per cent.; lymphocytes, 6 per cent.; transitionals, 2.2 per cent.; eosinophiles, 0 per cent. Iodin reaction negative. April 21, 1902: Diaphragmatic pleurisy developed, and patient died April 22.

Case 13.—P. M., aged 32 years, white. History: Complains of night sweats, cough and expectoration. Urine contains albumin. He was treated in the Pennsylvania Hospital from February 7 to March 19, 1902. Examination of sputum on February 8 showed cocci, but no tubercle bacilli; on February 14 tubercle bacilli were found. March 31, 1902, 3:00 p. m.: Temperature, 99; pulse, 80; respiration, 36. Erythrocytes, 4,620,000; leucocytes, 7,600; ratio, 1-607; hemoglobin, 73 per cent. Differential count, polymorphonuclears, 82.8 per cent.; lymphocytes, 14 per cent.; transitionals, 2.8 per cent.; eosinophiles, 0 per cent. Iodin reaction negative. April 14, 1902, 2:45 p. m.: Temperature, 99; pulse, 80; respiration, 24. Erythrocytes, 4,200,000; leucocytes, 10,200; ratio, 1-411; hemoglobin, 90 per cent. Differential count, polymorphonuclears, 77.6 per cent.; lymphocytes, 18.8 per cent.; transitionals, 3.2 per cent.; eosinophiles, 0 per cent. Iodin reaction negative. Patient died.

Case 14.—J. K., aged 44 years, white. History: Has had a cavity at the right apex for a number of years. The disease is non-progressive. March 31, 1902: Sputum contains tubercle bacilli and cocci. 4:00 p. m.: Temperature, 98; pulse, 84; respiration, 32. Erythrocytes, 4,440,000; leucocytes, 7,100; ratio, 1-625; hemoglobin, 75 per cent. Differential count, polymorphonuclears, 70.4 per cent.; lymphocytes, 20.4 per cent.; transitionals, 7.2 per cent.; eosinophiles, 2 per cent. Iodin reaction negative. Patient left the hospital improved, but still retaining the symptoms and signs of a cavity.

Case 15.—J. H., aged 33 years, white. History: Complains of cough, expectoration and great debility of 9 weeks' duration. Both apices involved; cavity at right apex; pneumonic area at left base. No diarrhea. April 15, 1902: Sputum contains tubercle bacilli and cocci. 2:30 p. m.: Temperature, 100.2; pulse, 150; respiration, 50. Erythrocytes, 4,200,000; leucocytes, 247,000; ratio, 1-17; hemoglobin, 60 per cent. Differential count, polymorphonuclears, 97.6 per cent.; lymphocytes, 2 per cent.; transitionals, 0.4 per cent.; eosinophiles, 0 per cent. Iodin reaction negative. Patient died at 2 a. m., April 16.

Case 16.—S. F., aged 29, black. History: Has been sick for 2 years. There is a cavity at the left apex; an area of consolidation at the right apex; pleuritis at both bases. General bronchitis, albuminuria, edema of the feet and laryngitis. No diarrhea. April 18, 1902: Sputum contains tubercle bacilli. 2:30 p. m., temperature, 102.4; pulse, 100; respiration, 22. Erythrocytes, 3,120,000; leucocytes, 8,100; ratio, 1-385; hemoglobin, 55 per cent. Differential count, polymorphonuclears, 87 per cent.; lymphocytes, 8 per cent.; transitionals, 5 per cent.; eosinophiles, 0 per cent. Iodin reaction negative. Patient died April 22.

Case 17.—E. F., aged 19 years, black. History: Patient has been sick for 3 months. Complains of cough, expectoration and chest pains. No diarrhea. Both apices involved; cavity of the right apex. April 21, 1902, 3:00 p. m.: Temperature, 102.6; pulse, 84; respiration, 44. Erythrocytes, 3,800,000; leucocytes, 7,600; ratio, 1-500; hemoglobin, 50 per cent. Differential count, polymorphonuclears, 77.2 per cent.; lymphocytes, 16 per cent.; transitionals, 6.4 per cent.; eosinophiles, 0.4 per cent. Iodin reaction negative. May 15, 1902. Patient has extensive pleuritis on right side. Bronchitis on both sides. 3:00 p. m.: Temperature, 101.4; pulse, 132; respiration, 34. Erythrocytes, 3,820,000; leucocytes, 7,000; ratio, 1-545; hemoglobin, 55 per cent. Differential count, polymorphonuclears, 80 per cent.; lymphocytes, 16.2 per cent.; transitionals, 4 per cent.; eosinophiles, 0 per cent. Iodin reaction negative. May 26, 1902: Patient is very weak and is confined to his bed. 3:30 p. m., temperature, 101.4; pulse, 132; respiration, 34. Erythrocytes, 3,020,000; leucocytes, 6,300; ratio, 1-479; hemoglobin, 55 per cent. Differential count, polymorphonuclears, 78.8 per cent.; lymphocytes, 19.2 per cent.; transitionals, 2 per cent.; eosinophiles, 0 per cent. Iodin reaction negative. June 1, 1902, 11:45 a. m.: Temperature, 98; pulse, 104; respiration, 28. Flow of blood sluggish. Patient very weak. Erythrocytes, 4,600,000; leucocytes, 9,600; ratio, 1-423; hemoglobin, 85 per cent. Differential count, polymorphonuclears, 80 per cent.; lymphocytes, 19.2 per cent.; transitionals, 0.8 per cent.; eosinophiles, 0 per cent. Iodin reaction negative. Patient died June 2.

Case 18.—J. P., aged 46 years, white. History: Complains of cough, hemorrhages, dyspnea and chest pain for 6 months. Involvement of both apices; cavity in posterior part of right apex. Hemorrhage on April 25, 1902. Has edema of the legs with albuminuria and casts. May 6, 1902, 2:30 p. m.: Temperature, 96.4; pulse, 108; respiration, 44. Erythrocytes, 4,010,000; leucocytes, 10,700; ratio, 1-375; hemoglobin, 75 per cent. Differential count, polymorphonuclears, 87.4 per cent.; lymphocytes, 7.4 per cent.; transitionals, 3.4 per cent.; eosinophiles, 1.8 per cent. Iodin reaction negative. Patient died.

Case 19.—A. R., aged 22 years, white, complains of cough and loss of strength of one year's duration. Consolidation of right apex and left base. May 8, 1902, 2 p. m.: Temperature, 101.6; pulse, 108; respiration, 40; erythrocytes, 4,280,000; leucocytes, 6,733; ratio, 1-635; hemoglobin, 70 per cent. Differential count, polymorphonuclears, 81.2 per cent.; lymphocytes, 12.4 per cent.; transitionals, 6.4 per cent; eosinophiles, 0 per cent. Iodin reaction negative. Died May 16, 1902.

Case 20.—W. C., aged 29 years, black. History: Complains of cough of 12 years' duration. Night sweats and free expectoration. Signs of cavity at right apex. No tubercle bacilli found, however. Sputum contains many cocci and elastic tissue. Urine contains a trace of albumin. May 13, 1902, 3:00 p. m.: Temperature, 98.6; pulse, 92; respiration, 24. Erythrocytes, 6,710,000; leucocytes, 12,400; ratio, 1-541; hemoglobin, 72 per cent. Differential count, polymorphonuclears, 73.6 per cent.; lymphocytes, 20.6 per cent.; transitionals, 5.4 per cent.; eosinophiles, 0.4 per cent. Iodin reaction negative. Patient left the hospital.

Case 21.—R. W., aged 35 years, white. History: Has had a cough for one year. Hemorrhage 7 months ago. Has locomotor *ataxia*. Cavity at right apex. Left lung not involved. May, 26, 1902, 2:30 p. m.: Temperature, 99.6; pulse, 120; respiration, 30. Erythrocytes, 5,240,000; leucocytes, 23,500; ratio, 1-223; hemoglobin, 85 per cent. Differential count, polymorphonuclears, 69 per cent.; lymphocytes, 22.6 per cent.; transitionals, 8 per cent.; eosinophiles, 0.4 per cent. Iodin reaction negative.

Case 22.—W. R., aged 38 years, white. History: Complains of cough and loss of flesh of 6 months' duration. Cavity at right apex, extensive pleuritis at left base posteriorly. Slight bronchitis. May 27, 1902: Sputum contains pus, epithelium, mucus, tubercle bacilli, diplococci, streptococci and bacilli. 11:45 a. m., temperature, 98.4; pulse, 108; respiration, 28. Erythrocytes, 5,420,000; leucocytes, 34,000; ratio, 1-156; hemoglobin, 65 per cent. Differential count, polymorphonuclears, 93.4 per cent.; lymphocytes, 3.6 per cent.; transitionals, 2.8 per cent.; eosinophiles, 0.2 per cent. Iodin reaction negative.

Case 23.—F. C., aged 44 years, black. History: Complains of cough and the expectoration of blood. Had two hemorrhages on May 25 and has expectorated blood since. No night sweats, no diarrhea. Signs of cavity at left apex. May 28, 1902: Sputum contains alveolar epithelium, pus, red blood corpuscles, cocci and bacilli. No tubercle bacilli found. 11:30 a. m., temperature, 98; pulse, 80; respiration, 20. Erythrocytes, 4,380,000; leucocytes, 15,800; ratio, 1-277; hemoglobin, 55 per cent. Differential count, polymorphonuclears, 78 per cent.; lymphocytes, 7 per cent.; transitionals, 14.4 per cent.; eosinophiles, 0.6 per cent.; no nucleated red cells. Iodin reaction negative. Patient had a hemorrhage on May 30, 1902. June 1, 1902, 10:40 a. m.: Temperature, 100.2; pulse, 80; respiration, 24. Erythrocytes, 3,430,000; leucocytes, 20,700; ratio, 1-165; hemoglobin, 55 per cent. Differential count, polymorphonuclears, 70 per cent.; lymphocytes, 20.8 per cent.; transitionals, 7.6 per cent.; eosinophiles, 1.6 per cent. Iodin reaction negative.

Case 24.—M. G., aged 21 years, white. History: Cavity diagnosed in posterior portion of left lung. Expectorates large quantities of foul-smelling material when he lies on his right side. Sputum contains cocci and bacilli, but no tubercle bacilli. An operation was done and a large pulmonary cavity was drained. At autopsy, the lower lobe of the left lung was found to contain a large number of cavities which contained a reddish material and which were due to the dilation of the bronchi. A similar condition was found in the posterior portion of the right lung. June 3, 1902, 11:30 a. m.: Erythrocytes, 4,750,000; leucocytes, 15,400; ratio, 1-308; hemoglobin, 70 per cent. Differential count, polymorphonuclears, 81.2 per cent.; lymphocytes, 16.6 per cent.; transitionals, 0.4 per cent.; eosinophiles, 1.8 per cent. Iodin reaction negative. Patient died.

Case 25.—A. A., aged 32 years, black. History: Illness of one year's duration. Complains of cough, expectoration, loss of weight, chest pain and night sweats. Dullness all over left chest with pleural frictions both in front and behind. Beginning cavity formation above left clavicle. Sputum contains tubercle bacilli. December 2, 1902, 3:30 p. m. Erythrocytes, 4,410,000; leucocytes, 15,200; ratio, 1-290; hemoglobin, 75 per cent. Differential count, polymorphonuclears, 81.6 per cent.; lymphocytes, 15.4 per cent.; transitionals, 2.8 per cent.; eosinophiles, 0.2 per cent. Iodin reaction negative. Jan. 3, 1903: Erythrocytes, 5,710,000; leucocytes, 10,600; ratio, 1-538; hemoglobin, 95 per cent. Differential count, polymorphonuclears, 58.6 per cent.; lymphocytes, 31.8 per cent.; transitionals, 7.2 per cent.; eosinophiles, 1.6 per cent.; myelocytes, 0.8 per cent. Iodin reaction negative. Cavity formation, on above date, had extended to third rib. Patient subsequently discharged from the hospital.

Case 26.—C. D., aged 38 years, white. History: Patient has been sick for 2 weeks with nausea, loss of appetite, pain in the abdomen, constipation, cough, expectoration and slight fever. Small area of consolidation at posterior portion of right apex, between the root of the neck and the spine of the scapula. Sputum contained tubercle bacilli. December 2, 1902, 3:30 p. m. Erythrocytes, 3,980,000; leucocytes, 10,000; ratio, 1-398; hemoglobin, 70 per cent. Differential count, polymorphonuclears, 67.6 per cent.; lymphocytes, 29.0 per cent.; transitionals, 1.8 per cent.; eosinophiles, 1.6 per cent. Iodin reaction negative. Jan. 3, 1902: Erythrocytes, 4,580,000; leucocytes, 16,600; ratio, 1-276; hemoglobin, 82 per cent. Differential count, polymorphonuclears, 62.6 per cent.; lymphocytes, 25.4 per cent.; transitionals, 8.9 per cent.; eosinophiles, 3 per cent.; myelocytes, 1 per cent. Iodin reaction negative. Patient left the hospital very much improved.

CONCLUSIONS.

1. The blood picture in pulmonary tuberculosis is not constant, and the conditions described by Grawitz[1] are by no means absolute. As can be seen by reference to the detailed results of the different examinations, there are cases in each of the three stages of the disease that are quite out of the limits of cellular and hemoglobin content described by him.

2. Omitting the exceptional cases from consideration, however, the average case in the first stage of the disease presents a slightly reduced number of erythrocytes, a moderate reduction of the hemoglobin and about a normal number of leucocytes. The average case in the second stage presents a varying degree of leucocytosis, due to an increase in the number of polymorphonuclear, neutrophile cells. The erythrocytes are present in about normal numbers, and the hemoglobin is often normal in percentage. The average cases in the third stage will show a reduction in the number of erythrocytes, a moderate leucocytosis composed of the polymorphonuclear, neutrophile cells and a high hemoglobin percentage.

3. Hemorrhage is usually followed by a marked reduction in hemoglobin, a slight reduction in the number of

erythrocytes. Leucocytosis is not an invariable feature of a post-hemorrhagic blood.

4. Albuminuria of itself appears to cause no constant change in the blood picture.

5. Tuberculous diarrhea is apparently attended by a reduction of the number of the erythrocytes and of the percentage of hemoglobin and by an increase of the leucocytes. The latter increase is due to the polymorphonuclear, neutrophile cells.

6. Pleurisy is usually accompanied by a polymorphonuclear, neutrophile leucocytosis.

7. There is no distinctive blood picture that will serve to differentiate between extensive cavity formation due to tuberculous degeneration and that due to other causes. Further, leucocytosis is not a constant feature of cavity formation.

8. The leucocytosis occurring in the course of pulmonary tuberculosis is due to an increase of the polymorphonuclear elements and not to an increase of the lymphocytes or of the transitional cells.

9. The absence of the eosinophile cells from the blood may be looked on as an unfavorable prognostic sign. The increase of these cells while the patient is under treatment may be taken as an indication that the progress of the disease has a tendency to become arrested.

THE PRESENT CONCEPTION OF THE PERIRENAL FASCIA

AND ITS RÔLE IN FIXATION OF THE KIDNEY.

D. D. LEWIS, M.D.
CHICAGO.

The introduction of cross sections into anatomic work has simplified to a marked degree the study of the fasciæ of the different regions of the body, and as a result we have at the present time accurate accounts of their osteal, muscular, vascular and visceral relations. Those fasciæ which are of the greatest surgical importance have received the greatest amount of attention, and the descriptions given of the cervical, axillary and pelvic fasciæ are fairly uniform. The fascia surrounding the kidney has not received the amount of attention that it deserves, and in the majority of text-books on anatomy and surgery no mention is made of it. In monographs devoted to renal anatomy and surgery, considerable space is given to the description of this fascia and the rôle that it plays in kidney fixation, but many who are interested in kidney work do not have access to these works, and of necessity remain unfamiliar with the attachments and visceral relations of the perirenal fascia.

The descriptions of this fascia that have been given vary considerably. These variations are dependent partly on actual variation of the fascia and partly on the methods employed in the investigation. With the introduction of improved technic for the preparation of cross sections, the descriptions have become much more uniform. It is hardly possible to conceive of the amount of patient study that has been devoted by a few investigators to this fascia, without giving the history of some of the earlier descriptions. The time at which a fatty capsule can be found surrounding the kidney and the part that it assumes in maintaining the kidney in its normal position, have not been definitely settled. An attempt will be made to give some of the late views concerning this subject.

THE PERIRENAL FASCIA.

Zuckerkandl first described, posterior to the fatty capsule of the kidney, a layer of fascia, which he considered to be derived from the lateral abdominal wall.[1] It is found anterior to the aponeurosis of the quadratus lumborum muscle, to which it is attached by fascial bands. If this fascia is traced toward the median line, it will be found to become continuous with the fibrous capsule of the kidney along its medial margin. Zuckerkandl did not describe any fascia passing over the anterior surface of the kidney, but states that after removal of the peritoneum an outer kidney capsule is found, which may become so condensed in emaciated subjects as to resemble a fascia.

Sappey[2] states that the kidney is surrounded by a fatty capsule and a fibrous sheath. This fibrous covering is derived from the subperitoneal fascia, which divides as it approaches the lateral margin of the kidney into an anterior and a posterior lamella. These two fascial lamellæ are attached to the fibrous capsule at the medial margin of the kidney and unite at its upper pole. The adrenal is excluded by this union from the special fascial compartment of the latter organ.

Nicolas[3] describes a fatty capsule, which surrounds the kidney on its anterior and posterior surfaces. The kidney is thus completely surrounded by fat, which is reflected at the hilus of the organ on the renal vessels.

Charpy[4] assigns to the fascia renalis an important rôle in maintaining the kidney in its normal position. He agrees with the other investigators in considering the fascia to be derived from the subperitoneal fascia, and describes the posterior and anterior layers as becoming continuous with the fibrous capsule of the kidney at its medial margin. From the point of attachment of the anterior layer of fascia to the fibrous capsule, a fascia is given off, which passes across the prevertebral vessels to become continuous with the corresponding fascia of the opposite side. According to this anatomist, intra-abdominal pressure and the peritoneum play an important secondary part in kidney fixation.

All the above descriptions differ somewhat as to the attachments of the layers of the perirenal fascia, and one makes no mention of a constant anterior layer. The latest description, as given by Gerota,[5] differs from all the preceding, and his findings can be verified on examination of cross sections passing through the region of the kidney. He agrees, however, with Sappey and Charpy as to the origin of this fascia. In the accompanying figures the origin and distribution of the fascia, as he has described it, can be easily seen.

As the subperitoneal fascia approaches the lateral margins of the kidneys, it divides into a prerenal and a retrorenal layer. The prerenal layer varies in consistency. In some cases it is quite firm and resistant, while in others it is represented by only a few strands of connective tissue. It covers directly the anterior surface of the kidney, and the fascial bands which are given off from it fuse with the kidney capsule proper. If this fascia is traced toward the median line, it will be found to pass anterior to the inferior vena cava and the abdominal aorta to become continuous with a corresponding fascia of the opposite side. This layer of fascia is so thin and varies so much in consistency that it is rather difficult to conceive that it alone could aid in the support of the kidney; but one must consider in this connection the

"fascia of fusion," to be described later, and the colon, which are intimately related to the anterior surface of the kidney.

The retrorenal fascia of Zuckerkandl lies posterior to the fatty capsule of the kidney and anterior to the aponeurosis of the quadratus lumborum and psoas muscles. Anteriorly it is connected to the fibrous capsule of the kidney by strong fascial bands. Its attachment to the aponeurosis of the quadratus lumborum and psoas muscles, posteriorly, is so firm that it is probably never detached. At the lateral margin of the psoas muscles a process is given off from this layer of fascia which passes into the base of the transverse process of the lumbar vertebræ. Medially to the psoas the fascia is attached to the lumbar vertebræ and to the anterior common ligaments of the spine. Gerota has found in some of his specimens a well-defined ligament, which passes off from the retrorenal layer of fascia to be attached to the fourth lumbar vertebra.

If tracings of the prerenal and retrorenal layers of the fascia are made in sagittal sections, the following arrangement will be found: These two layers fuse above and are attached to the diaphragm. They do not unite, as Sappey describes, at the upper pole of the kidney, thus excluding the adrenal from the special fascial compartment of the kidney. Below, these layers of fascia do not fuse, but gradually become lost in the fat and fascia of the iliac fossa. It will be seen from the above description that the kidney and adrenal are maintained in a fascial compartment. The retrorenal layer of fascia, being connected as it is by firm fascial bands with the fibrous capsule of the kidney anteriorly and with the aponeurosis of the quadratus lumborum and psoas muscles posteriorly, is a much more important factor in maintaining the kidney in its normal position than is the prerenal. These fascial bands may become relaxed and atrophic, and thus permit of displacement of the kidney within its fascial sheath.

"FASCIÆ OF FUSION."

Anatomists are indebted to Toldt for their knowledge of the series of changes by which the primitive straight intestine of the embryo becomes the convoluted intestine of the adult. In the embryo the anterior surface of the kidney is covered by parietal peritoneum and the future colon occupies a median position, attached to the vertebral column by a long primitive mesocolon. The future colon undergoes a series of rotary changes, passing from right to left, so that, finally, the cecum lies in front of the lower pole of the right kidney and the descending colon covers two-thirds of the anterior surface of the left kidney. At this stage in embryonic life there will be found anterior to the left kidney three superimposed planes of peritoneum. These layers are the primitive parietal peritoneum and the two layers of the mesocolon. The two layers of the mesocolon fuse and later fusion with the parietal peritoneum occurs. As the result of this fusion a fascia is formed to which Toldt has given the name of "fasciæ of fusion." The definitive parietal peritoneum represents, then, the original mesocolon and the primitive peritoneum remains as a "fascia of fusion."

The extent to which the kidney is covered by the fascia depends on how great an area of the kidney is covered by the colon. On the left side two-thirds of the anterior surface of the kidney will be covered by the fascia, and on the right side only the lower pole. This fascia may not be found in all cases, for in 26 per cent. of the cases on the right side and 36 per cent. of the cases on the left, the formation of this fascia does not occur, and in these cases the ascending and descending colons retain their peritoneal folds as a distinct mesocolon, attaching them to the posterior abdominal wall.

THE FATTY CAPSULE OF THE KIDNEY AND THE PARARENAL ADIPOSE BODY.

Anatomists differ as to the time that the fatty capsule of the kidney develops, to what extent it covers the kidney, and as to how much of a factor it is in fixing this organ. It seems to be the general opinion that the fatty capsule attains its greatest development along the lateral margin of the kidney and its lower pole. At the medial margin of the kidney it becomes continuous with the fat of the renal sinus and is reflected along the ureter and spermatic vessels downward into the pelvis. In the majority of cases no fat will be found on the anterior surface of the kidney.

Sappey states that the fatty capsule does not appear until the eighth or tenth year. Gerota and Tuffier have found a fatty capsule present at a much earlier date. The former has found a well-defined fatty capsule during the first and second years of life, and the latter states that it is present in the new-born.

Tuffier[6] does not assign to the fatty capsule any part in the fixation of the kidney. In some exhaustive animal studies he has found that the kidney undergoes movements isochronic with the pulse beat (movement of expansion) and movements isochronic with the respiration (movement of translation). He believes that the fatty capsule aids these movements and considers it as quite comparable to the fat surrounding the bulb of the eye, the rectum and the bladder. Gerota states that a moderate deposit of fat may have some influence in rendering the fascial septa passing from the retrorenal fascia to the fibrous tunic of the kidney stronger and keeping them tense. Gerota suggests that the fatty mass occupying the triangular space between the quadratus lumborum, the psoas and the iliac crest be known as the "corpus adiposum pararenale." It is derived from the subperitoneal fat. Its position and extent are well shown in the accompanying figures. It lies between the retrorenal and transversalis fasciæ. In perinephritic processes ending in pus formation, these fatty bodies may exercise some influence on the gravitation of the pus. In case the fatty capsule of the kidney is affected, the pus will gravitate along the ureter and spermatic vessels into the pelvis. Pus arising from inflammation of the pararenal adipose body will discharge at Petit's triangle or burrow downward into the iliac fossa.

As recently suggested by Professor Keen, the pararenal adipose body and the retrorenal fasciæ are important guides in kidney surgery. After incision of the quadratus lumborum and the anterior layer of the lumbar fascia, the pararenal adipose body will be exposed. Just anterior to this will be found the dense, shining retrorenal fascia, which lies just posterior to the fatty capsule of the kidney.

Gerota has demonstrated in his work that the adrenal assists in maintaining the kidney in position. This is especially so in children. In experimenting on the cadaver of a child he found that a traction amounting to between 750 and 1,000 grams must be exerted before the adrenal and the kidney separate. In the adult the kidney becomes so much larger than the adrenal that the latter probably has no influence whatever.

The perirenal fascia may be regarded as the most important factor in maintaining the kidney in its normal position, but we should never lose sight of the fact, however, that the neighboring organs, peritoneum, fatty capsule and intra-abdominal pressure are important accessories.

Harris[7] and Andrews[8] were among the first to realize the full surgical significance of this fascia and its importance in kidney fixation. The former attempts, after the removal of the perirenal fat, to diminish, by suturing, the size of the fascial compartment in which the kidney lies. If the pouch is very large and the peritoneum bulges to the medial side of the colon, a small opening is made into the peritoneal cavity to the outer side of the colon and sutures are passed through the mesocolon from within. This layer is then approximated to the posterior abdominal wall, diminishing the size of the compartment. Care should be exercised to avoid injury of the arteria colica dextra or sinistra, as the case may be. As a final step in the obliteration of the compartment, the prerenal fascia is sutured to the lumbar fascia posterior to the line of incision through the abdominal wall. Andrews, in his "reefing" operation, splits the fatty capsule of the kidney longitudinally. The retrorenal fascia is supposed to be included within the fat. These two flaps are pulled out through the line of incision and retained in this position, while mattress sutures are passed through the muscles and tied. The fatty flaps thus lie outside of the incision and are retained in position by the pressure of the coapted cut surfaces. Andrews devised this operation because he found that the fascia and fat were too friable to retain sutures. Harris and Andrews have reported a series of cases, and the results obtained from their operations are good.

The good results obtained from the Senn method of gauze packing are dependent on the broad bands of adhesions forming between the lower pole of the kidney and the retrorenal fascia. If, after removal of the fatty capsule of the kidney, the retrorenal fascia were exposed and sutured directly into the fibrous capsule of the kidney, good and lasting results should be obtained. This direct suture could be most easily combined with the Senn method. Direct suture would certainly be more advantageous than any of those methods by which the kidney capsule is retained against the retrorenal fascia by sutures passed through the kidney parenchyma.

We can not depend on sutures to hold these two in apposition long enough to insure a reaction leading to the formation of adhesions.

THE VALUE OF AN INJURY.*

L. SEXTON, M.D.
District Surgeon of the Louisville & Nashville R. R. and of the Illinois Central R. R.
NEW ORLEANS.

We all understand that compensation is both an underlying law of nature and also the law of the country *in fixing the amount* of damages, and it may be said that in fixing the value, cost or price, as you may choose to term it, of any injury, the law of compensation is the guiding star by which the measure of damages in the instant case is to be determined. The difficulty in the situation is to apply the rule of compensation to each individual case as it arises. We are told by the law books that "compensation is the basic principle of the law of damages, the measure thereof being limited and controlled, and the elements of recovery primarily determined by this fundamental consideration." We are also told by the books that "there are frequently elements involved so wholly insusceptible of money valuation that the measure of recovery must be left largely, if not entirely, to the discretion of the jury. This is noticeably the case in actions for damages for personal injuries where physical suffering has resulted, and likewise where mental distress has been a consequence of the defendant's act."

When we remember how difficult it is to fix any sort of estimate on physical suffering, and how much more difficult it is to measure mental distress by the standard of a dollar, we realize the difficulty of discussing the subject in hand.

As I have already indicated, the jury generally fixes the price in such cases, and unless the verdict is so excessive or so grossly inadequate as to indicate passion, prejudice or corruption, it will generally be allowed to stand, though the courts presiding in such cases have always asserted and exercised the right of setting aside such verdicts as, in their judgment, are so wholly disproportionate to the injury suffered as to indicate passion, prejudice or corruption on the part of the jury.

While this is true, we are told, to use the language of legal books, that "In no other class of cases does the amount of damages rest necessarily so largely in the discretion of the jury as in those involving a recovery for the infliction of personal injuries, and the courts are very loath to interfere with a verdict in such cases in the absence of plain evidence that the jury have abused the discretion vested in them."

It must be patent in the outset to every thinking mind that the value or cost of all injuries must, in the nature of the case, be extremely relative. The loss of one's eyes would not mean the same in dollars and cents, at least, to the day laborer and to the accomplished surgeon. The loss of life itself would not mean the same in dollars and cents to the family of a young, vigorous man who gave promise of many years to live, and of a man earning the same salary whose age and infirmity was such as to render it certain that his labors were almost at an end.

At the risk of appearing a little tedious, I shall now call the attention of my auditors to a few cases which have "passed muster" in the courts of the country, in which verdicts for various elements of injury have been rendered, and the judgments entered thereon have been approved by the courts of last resort.

In the case of Morgan vs. Southern Pacific R. R. Company, decided by the Supreme Court of California, the plaintiff was a woman and the injury was permanent, amounting practically to total disability, and the verdict, which was for $15,000, was sustained.

In the case of Chicago vs. Leseth, decided by the Illinois Supreme Court, the plaintiff suffered from a displaced womb, resulting in permanent injury to health. The verdict was for $15,000 and was sustained by the court.

In the case of Bennet vs. New York Central R. R. Co., an $8,000 verdict, in a case of curvature of the spine, was sustained by the Supreme Court of New York.

In the case of International R. R. Co. vs. Mulliken, decided by the Supreme Court of Texas, $4,000 was held to be a reasonable verdict for "incurable spinal disease."

In the case of Osborne vs. Detroit, reported in "32d Federal Reporter," $10,000 was held to be a reasonable verdict for an injury resulting in paralysis of one-half of the body; and in the case of Bishop vs. St. Paul City R. R. Company, the Supreme Court of Minnesota held that $15,000 was a reasonable verdict for the same injury.

The Supreme Court of Wisconsin held, in the case of McMahon vs. Eau Claire Water Works Co., that $5,000 was not an unreasonable verdict in case of an injury causing "paresis or progressive paralysis."

A very interesting case will be found in "86th Georgia Reports," which is styled Georgia Pacific R. R. Co., vs. Dooley, in which a $16,000 verdict was upheld for an injury resulting in the "displacement and enlargement of the heart."

The case of Dieffenbach vs. New York Central R. R. Co., presents a case of a very severe injury, not necessarily permanent, and the plaintiff, who was a young man earning more than $4,000 a year, recovered a verdict of $25,000, which was allowed to stand.

There is a case recorded in the "78th Federal Reporter," where a $5,000 verdict was allowed to stand for an injury resulting in the "impairment of muscular sense, feeling and partial loss of hearing."

The total loss of vision was the result of an injury, for which suit was brought in the case of Stearns vs. Reidy, reported in "105th Illinois Reports," and a verdict of $9,000 was held to be reasonable.

A $14,000 verdict was sustained in the case of Wallace vs. Vacuum Oil Company, decided by the Supreme Court of New York, in which the injury is described as "the loss of eye and other serious injuries."

A verdict of $100 was sustained by the Supreme Court of New York for an injury described as "a black eye."

The loss of a leg was held to justify a verdict of $2,300 in the William Branfoot case, reported in "52d Federal Reports," and the loss of both legs was held to justify a $15,000 verdict by the courts of Arizona, a $13,000 verdict by the courts of Colorado, and a $25,000 verdict by the courts of Illinois. The difference in amounts in these cases doubtless depended on the different state of facts presented in each case. The loss of both legs to a common laborer, earning a dollar a day, would be a very different thing, when measured by dollars and cents, to the loss of a leg by a civil engineer whose salary was $10,000 per annum. The loss of a foot was held to justify a verdict of $9,000 by the Supreme Court of Georgia in the case of Georgia Railroad, etc., Co. vs. Keating; and a verdict of $11,000 by the Supreme Court of New York in the case of Jordan vs. New York Central R. R. Co., and in the case of Commerford vs. Atlantic Avenue R. R. Co., the Supreme

---

* President's address before the American Academy of Railway Surgeons, Chicago, Oct. 1-2, 1903.

Court of New York sustained a verdict of $8,500 for the loss of several toes.

In the case of Chipman vs. Union Pacific Railroad Company, reported in "12th Utah Reports," the plaintiff was a child who had lost her foot and the recovery was $10,500, and the verdict was sustained.

In the case of the loss of an arm a $5,000 verdict was sustained in one case by the courts of Arkansas, an $8,000 verdict by the Supreme Court of Illinois, a $4,000 verdict by the Supreme Court of Iowa, and a $9,119 verdict was sustained by the Supreme Court of Texas in the case of Missouri, etc., R. R. Co. vs. Kirkland, while the Supreme Court of Wisconsin sustained a $10,000 verdict for the same injury.

The loss of a hand has been variously estimated by approved verdicts ranging from $1,250 to $5,000 in cases reported by various courts. The loss of fingers has been the prolific mother of many damage suits, and the verdicts have ranged all the way from a few hundred dollars to $8,500, which was the amount of the verdict in the case of Ridenhour vs. Kansas City Cable R. R. Co., in which case all the fingers on one hand were disabled.

For injuries resulting in death the verdicts which have been rendered and sustained by the courts of the country, in the nature of things, show the greatest possible variation, and it would serve no useful purpose to undertake to classify them. It would seem but natural that verdicts in such cases should run higher than in cases resulting in the loss of a limb, but it is a curious fact that such is not ordinarily the case, and the well-informed personal injury agent and railroad attorney would ordinarily prefer to defend a case of an injury resulting in death rather than one resulting in permanent disability. The reason is not very obvious, though it is sometimes accounted for by the fact that a jury has more sympathy for a permanent cripple than for the heirs or representatives of a dead man, whose injuries are covered by the grave. Like all other rules, this one has its exceptions, and a pretty widow and orphan children, as plaintiffs, have frequently caused verdicts to rise very high in the scale when compared with the earnings of the deceased.

It will be remembered that it is the province of the courts not only to set aside verdicts which are considered excessive and oppressive, but it is also their province to set aside such verdicts as, in their judgment, may be inadequate, and it will be of interest to the profession to know that, so far as my investigation has gone in the leading legal authorities on this subject the highest verdict which is reported to have been set aside was that in favor of a physician. I refer to the case of Phillips vs. London, etc., R. R. Company, reported in "29th Moak," on page 177, where a verdict of £7,000 for "injuries sustained by plaintiff through the negligence of the defendant," was set aside as inadequate on the ground that "the jury must have omitted to take into consideration some of the elements of damage." "The plaintiff, who was a physician in the prime of life, having a practice worth, perhaps, £7,000 per annum, was reduced by the injury to a condition of helplessness, with every enjoyment of life destroyed, and with the prospect of a speedy death."

While at first thought, it would seem that a verdict of $35,000 appears pretty large, and while any railroad company which was called on to pay that much for any of us would consider itself pretty unfortunate, still, when it is remembered that this amount only represented about one year's earnings of the plaintiff in the case, that his life was rendered a burden and greatly shortened by the accident, it is manifest that the verdict should have been set aside as utterly inadequate.

While some of our clients may not be able to appreciate the justice of some of the verdicts hereinbefore mentioned, and while some were doubtless influenced, to some extent at least by passion and prejudice, yet, after all, it is the duty of every good citizen to bow to the majesty of the law, ever remembering as has been said:

> Of the law there can be no less acknowledged than that her seat is in the bosom of God; her voice in the harmony of the world. All things in heaven and earth do her homage, the very least as feeling her care, the greatest as not exempted from her power, both angels and men and the creatures of what condition soever, though each a different sort and manner, yet all are with uniform concert, admiring her as the mother of their peace and joy.

The railroad surgeon can not prevent injuries, but he can very materially lessen the loss or damage thereto by careful and skillful attention to each case submitted to his individual care. In proportion as he lessens the cost of such injuries, will his services be valuable to the companies whose interests are committed to his care.

Clinical Reports.

MYCOSIS FUNGOIDES.

CASE REPORT WITH AUTOPSY AND HISTOLOGIC REPORT.

JOHN C. HANCOCK, M.D.
DUBUQUE, IOWA.*

The report of this case is offered in view of the comparatively rare occurrence of the disease, and the question as to whether the process is that of infection or neoplasm, the unfavorableness of the prognosis, and the futility of treatment.

History.—B. D. S., 39 years old, male, married, clergyman, was born in Missouri, but now resides in Iowa. He denies alcohol, tobacco and venereal history. I saw him June 29, 1899.

Family History.—Father died at 71 years and had "gravel"; mother living at 73 years and well; five brothers living and well, one brother died of typhoid; two sisters living; one sister died of "croup"; otherwise negative. Wife and five children are living and well.

Previous History.—Whooping cough at 4, chicken-pox at 5, scarlet fever at 6, measles at 10, pneumonia at 14, mumps and influenza at 30. During the 17 years preceding the present illness, patient had several varieties of skin lesions more or less obscure as to character. At 22 years he had an eruption on right side of trunk, left shoulder, thigh and groin. The spots were yellow to red, not elevated, irregular in shape and confluent, accompanied by burning and itching but without scaling. Arsenic internally and iodin locally caused this eruption to disappear. At the same time, and at intervals for thirteen years after, had cankers in mouth.

Present Illness.—This began six years ago with itching and burning on soles, palms, backs of knees and other joints, and was not accompanied by any visible eruption. The itching gradually increased, and the palms and backs of hands began to crack without any other signs of disturbance. About three years ago, with further increase of itching, flat areas bluish-pink or light purple, the size of finger nails, appeared. These areas were the seat of burning and itching, especially in presence of moisture. Slight thickening and fissuring of the discolored areas began, and line of demarcation from normal skin became distinct. The lesions on exposed parts were the most marked, and desquamation occurred. Nine to ten months ago in the center of these areas, pea-sized, round discrete elevated nodules appeared. These gradually increased in size, uniformly in most instances, but also irregularly, and became the centers of the most intense itching and burning. Some, after increasing in size, broke down, forming ulcers, while others, regardless of size or shape, became absorbed without breaking down. Still others showed absorption in segments of any shape or size, often leaving a furrow between the original segments. Sometimes one-half of a tumor absorbed while the other broke down or became absorbed later on. Absorption also started in the center and proceeded concentrically in some cases. Ulceration took place in the same irregular ways. After ulceration and healing the area became covered with skin, which, however, remained discolored. With the advent of the tumor masses and ulcers nine months ago patient began to have fever. The ulcers gave off a foul pus. Feb. 9, 1899, the patient consulted Dr. J. Nevins Hyde of Chicago, who made the diagnosis of mycosis fungoides.

Examination.—June 29, 1899, patient presented himself with the diagnosis of mycosis fungoides to Dr. G. A. Staples, who referred him to me for treatment. He was a man over six feet high, weighing 165 pounds, well built and still fairly well nourished. Examination showed extensive and marked skin lesions. These, as partially indicated by photographs, were at the outer canthus of the right eye, right angle of the mouth, both sides of neck beneath the lower jaw, back of neck, both shoulders and axillæ, extending from the left downward and inward over pectoral region toward nipple, both elbows, wrists and hands, palms and dorsum, both hips, external genitals, both thighs, but more particularly the left, both knees, and the left calf. The feet at this time were only slightly involved. These areas consisted of a plateau of indurated purplish-pink slightly scaling skin, sharply defined with reference to normal skin having without any system or regularity, either as to distribution or size, nodules varying in size from that of a large shot to that of half a pear. The elevated areas were not tender, but itched and burned. Fissures, especially on the exposed parts, were conspicuous and in the natural folds the skin was noticeably tough and thick. These areas changed slowly and seemed on the whole to advance. The tumors seemed to take origin in the skin, and were freely movable with it. For the most part, the base was broad, but in some cases the tumors were attached by pedicles. The tumors were solid, hard masses without fluctuation. In the course of their careers they grew slowly to the size of a hazel nut or larger, remained indefinitely, broke down in ulcers, or became absorbed. There seemed to be no rule or system governing their course. In breaking down to form ulcers or in absorbing, there was no uniformity in the same or adjacent tumors. Some absorbed across the center, leaving irregular masses to remain or be absorbed later or to ulcerate. The largest tumor to the right of and posterior to the scrotum was the size of a split pear. Ulcers formed in the same irregular way. On the outer and anterior aspect of the left thigh will be seen in the photos the largest ulcer. This measured 1½ by 2 inches. The ulcers presented elevated irregular thickened margins with uneven indurated centers covered for the most part with tough sloughs and pus. The ulcers were not tender to the touch. The pus was foul smelling and resembled ordinary pus in appearance. Beside this eruption there appeared from time to time, chiefly on the abdomen, the chest and the back, parts not much involved by the eruption described above, flat, discrete and confluent pink to purple lesions. These caused increased suffering from itching and burning. This eruption disappeared and recurred, but was present more than half of the time the patient was under observation. The superficial lymph glands were uniformly and slightly enlarged and not tender. Slight edema of the feet and ankles was present. Reflexes were normal. Heart and lungs and abdominal organs were negative. The urine in August, 1899, was 64 ounces in 24 hours, slightly acid; sp. gr. 1.012; slight possible trace of albumin; no bile or sugar; urea, 20.544 grams in 24 hours. In September, amount 31 ounces, pale, slightly acid; sp. gr. 1,011; one-eighth per cent. albumin, and urea 11.9 grams in 24 hours: sugar and bile absent.

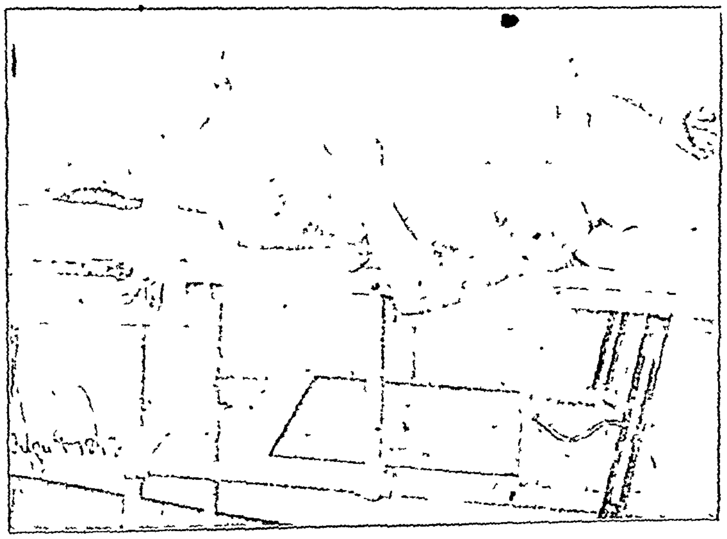

Fig. 1.- Case of mycosis fungoides, August, 1899

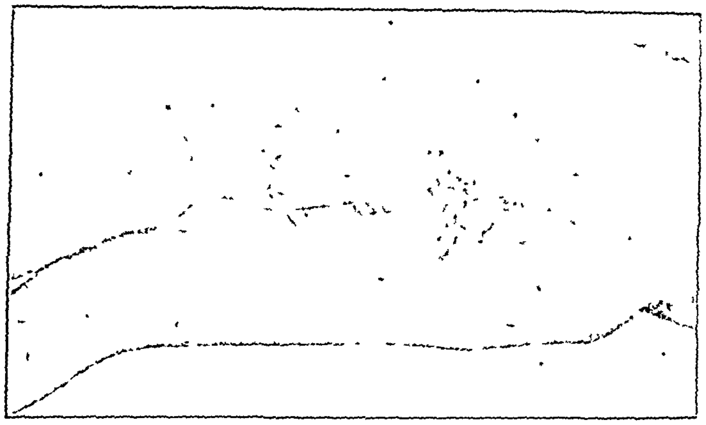

Fig 2 —Mycosis fungoides, August, 1899.

When the patient left for home, his weight had dropped to 152½ pounds. His subsequent history and the pictures were furnished by Dr. J. W. Kirkpatrick, Wyoming, Iowa, under whose care he remained until his death, in August, 1900. Dr. Kirkpatrick's report is as follows:

Course.—"Rev. B. D. S. came under my care in October, 1899. At that time he was able to be up and around the house all day, and did not suffer much pain aside from the itching and burning. The disease was present on the feet, legs, buttocks, hands, arms and one shoulder. The face and scalp did not become involved, excepting one ulcer at the corner of the mouth. The abdomen and chest were quite free from the disease. During the winter he began to have attacks of fever, which I believed to be septic, although every effort was made to keep the diseased parts scrupulously clean. At these times the temperature frequently went to 104 or 105 degrees, persisted three or four days, and then gradually subsided.

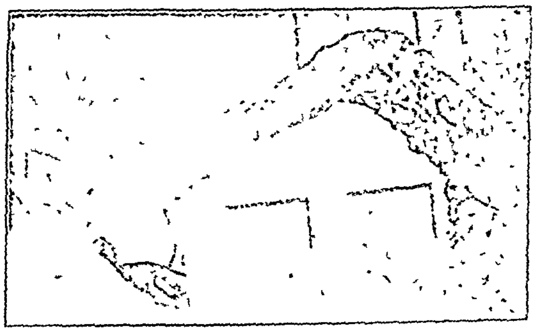

Fig 3 —View of leg later Figures 3, 4 and 5 are from photographs taken by Dr J. W Kirkpatrick, Wyoming, Iowa, some months later than Figures 1 and 2

Treatment.—"I used the Finsen light treatment on him for about six weeks, beginning in June. On the parts where the ulceration was not so deep, there was a very perceptible improvement. Many of the smaller ulcers on the feet healed entirely, but on the larger places it did not have the same effect, but rather made the parts more tender. I discontinued the treatment because it was evident that at best it could not have more than a palliative effect and the disease had already invaded the vital organs, and had sapped his vitality till it was very evident that the final issue could not be long delayed. I believe that this treatment in the earlier stages of this disease might be of utility."

The treatment of this disease as recommended by the authorities is both general and local, and from its variety seems to rest on no rational basis, and this goes to show that the relation of etiology, pathology and treatment leaves much to be determined. Practically all the remedies mentioned in works on diseases of the skin were tried at various times without any real or lasting effect being produced. The routine measures used to relieve the itching and burning and to secure cleanliness were warm baths of various kinds followed by the application of various ointments, powders and lotions, and the parts bandaged and dressed. These measures were but indifferently successful and sedatives were frequently necessary to secure rest and sleep. Arsenic internally was pushed to the limit of tolerance, with but slight and transitory effect. Subcutaneous injections of arsenic into the tumors caused sloughing of same, but other tumors appeared faster than those treated disappeared. Liq. iodi comp, as an injection was also tried Beta-naphthol and camphor combined were used internally and externally without effect. Thyroid extract internally produced no effect. Radiotherapy, as recommended by Hyde, was not tried, unfortunately, the patient having gone home. Finsen light, as mentioned by Dr. Kirkpatrick, produced no appreciable benefit.

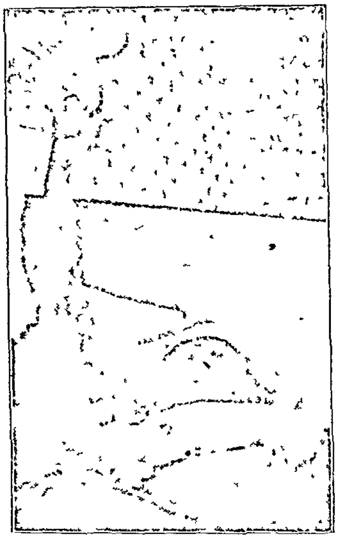

Fig. 4.—View of arm

Autopsy.—In August, 1900, the patient died, and by previous arrangement I was notified, and 18 hours after death performed the autopsy. The body had already been injected with formaldehyd. The conspicuous features were: (1) extreme emaciation, (2) skin eruption, (3) negative findings of the viscera. Emaciation had progressed to such an extent that no fat was to be made out macroscopically under the skin, in the mesentery, omentum, retroperitoneal or perirenal regions, or about the heart or other organs. On the surface of the body, more particularly on the buttocks, perineum, thighs, knees, ankles, feet, arms, hands, face, and back of neck were tumors varying in size from that of a pea to that of a small orange. Some, having broken down, had become large ulcers, presenting elevated, irregular, firm margins with uneven pitted centers, covered with sloughs and pus. Postmortem changes had reduced the tumors in size and consistency. The bases and the pedicles had their attachment in the skin entirely. Some tumors were easily detached, while others were firmly bound down to surrounding skin. About the tumors were areas of infiltration, brown in color, with free desquamation. On opening the abdominal cavity the viscera, except for absence of all fat, were normal. In the right pleural cavity the lung was extensively adherent to its parietes. Both lungs showed some hypostatic congestion posteriorly, otherwise the heart and the lungs were normal. The superficial lymph glands were enlarged, but the deep ones were not enlarged.

Histology.—The histologic report of the specimens is kindly furnished by Dr. J. H. Wright, director of the Clinico-Pathological Laboratory of the Massachusetts General Hospital, Boston. Since the case reported, Wright has examined two others and has found essentially the same pathologic conditions present.

"The material had been preserved in Zenker's fluid and in alcohol. It consisted of portions of skin, some of which presented tumor formations, and portions of lung, liver and spleen.

"Microscopic examination of sections of the material from the skin shows that the tumor formations are composed essentially of a very cellular tissue. In the sections the tissue has the appearance of being made up essentially of closely packed small cells among which a relatively small amount of connective tissue stroma as well as a fair number of capillary blood vessels are distributed. Over wide areas the stroma was only made easily visible in the form of a reticulum of fibrils by the use of Mallory's connective-tissue stain.

"The cells which make up the greater part of the tumors vary greatly in size and appearance. The prevailing cell has little or no cytoplasm, and usually has a very irregularly shaped, shrunken or wrinkled-appearing nucleus in which there are few or no nuclear granules. The size of these cells varies, some of them being smaller than lymphoid cells, but probably most of them slightly larger than lymphoid cells. Their nuclei are very different in appearance from the deeply staining, round or oval, granular nuclei of lymphoid cells. Another kind of cell has a large, pale-staining irregular nucleus and an indefinite amount of cytoplasm. Besides these cells there are other structures staining more or less deeply with nuclear stains and apparently representing degenerated nuclei. In places polynuclear eosinophilic leucocytes are scattered among the cells of the tumor. The epidermis over the tumors is more or less atrophic and distorted.

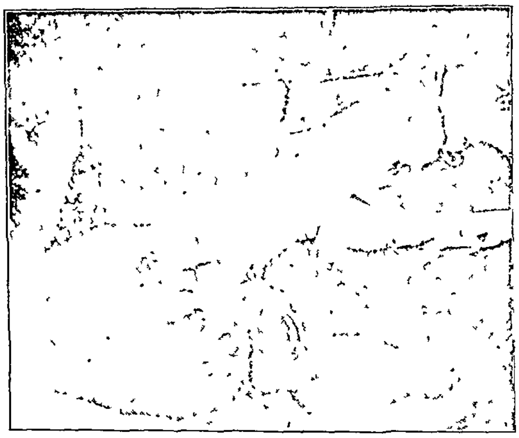

Fig. 5.—View of nates.

"In sections of the skin, in which no gross tumor formation was apparent, infiltrations and aggregations of the same cells as those described above in the tumors are present in the corium and around sweat glands.

"The study of the sections from the skin and from the tumors strongly suggests that the tumors have arisen as infiltrations in these situations.

"No bacteria or other parasites were observed in the sections.

"In general the histologic structure of the tumor tissue is very similar to that of the sarcoma originating in lymphadenoid tissue, that is lymphosarcoma. It also has some similarity to that of syphilitic lesions.

"In my opinion the neoplasm in this case should be classed as a sarcoma. If one accepts the widely spread belief that lymphosarcoma and similar neoplasms are caused by parasites, he will regard the new growth in the present case as also caused by a parasite. I do not hold this view, however.

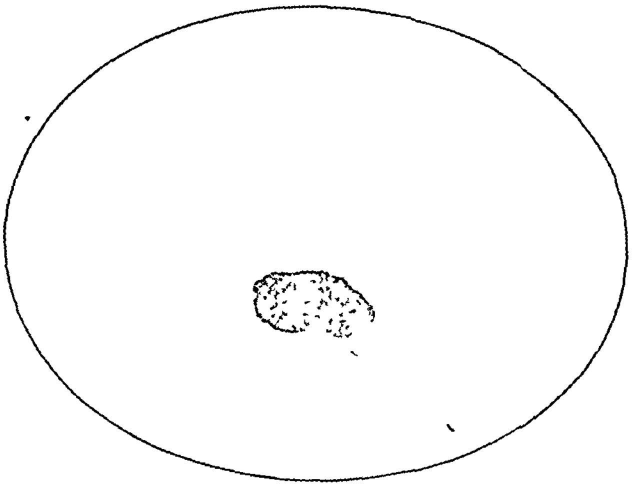
"Microscopic examination of sections of the liver, lung, spleen and kidney shows nothing worthy of mention."

URETERAL INJECTION OF OIL FOLLOWED BY THE SPONTANEOUS PASSING OF A URETERAL STONE.

LOUIS E. SCHMIDT, M.D.
CHICAGO.

Mrs. P., age 35 years, married 10 years. Family and previout history gives no information. Present sickness commenced in June, 1897, with a sudden colicky pain in the right iliac region and lancinating pains down the inner surface of the right thigh. This attack lasted 20 hours, and during this period Dr. Etheridge found a copious quantity of blood in the urine, and was obliged to give morphin hypodermatically to alleviate the pain. Since then the patient has had repeated typical attacks of renal colic; however, the pain was more or less localized in the right iliac region, and the attacks were never as severe as the first. A skiagraph taken in December, 1902, showed the outlines of a ureteral stone. The dull ache and tenderness always corresponded to this point.

Drs. Harvey and Paddock referred the case to me Jan. 5, 1904. I catheterized the right ureter and several centimeters from the ureteral orifice a slight obstruction was felt, but the catheter glided over it readily. To collect a sufficient quantity of urine to establish the sufficiency of the kidney in case of needed surgical interference, the catheter was left in place for two hours. At the end of this time 12 c.c. of sterilized albolene were injected into the pelvis of the right kidney, 8 c.c. were injected along the ureter as the ureteral catheter was gradually withdrawn. There immediately followed a dull ache in the right lumbar region and down the right iliac region. Although this was not as severe as any of her attacks, yet it was of such character as to necessitate her resting for some minutes before leaving the office.



The pains and the dull ache of which she had complained since the beginning of her present sickness became more severe than they had been for the past years. Finally, during the morning of January 12, the pains in the right iliac region became very severe. She became uneasy, and in order to distract her attention she sat down to the sewing machine. In a few minutes the patient, as she described it, "felt something give way." She was then obliged to urinate, and passed the stone which is here shown. Since then a skiagraph has been taken and the plate shows the absence of the stone, in contradistinction to the skiagraph taken in December, 1902. Since the passing of the stone the patient feels considerably better, especially mentally, as she knows the stone no longer exists in her ureter.

1003 Schiller Building.

A CASE OF EXFOLIATION OF THE ANTERIOR ARCH OF THE ATLAS.

RICHARD H. BROWN, M.D.
Associate Clinical Professor of Diseases of the Ear, Nose and Throat, Medical Department University of Illinois.
CHICAGO.

J. P., aged 30, a Bohemian, was employed in a carriage factory. He was extremely pale and emaciated, and the principal symptom that at once attracted attention was the fact that he carried his head and shoulders as rigidly immovable as though clamped in a vise. In expectorating, he would bend from the waist, shielding his neck in every movement. He complained of very severe pain in his throat and in the muscles of his neck.

Examination.—An angry ulcer was found, oval in outline, and about a centimeter in its longest diameter, on the posterior wall of the pharynx, a little above the level of the soft palate. There was a profuse purulent discharge and great inflammation of the parts around. Further examination showed marked enlargement of the glands over the entire body, with a mottled eruption, mucous patches in the mouth, and a low-grade fever. There was no difficulty in diagnosing the case as syphilitic.

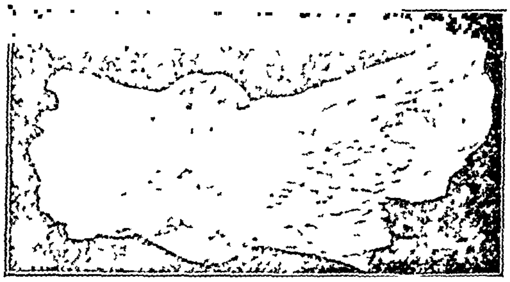


Fig. 1.—The exfoliated portion of the atlas, anterior view.

History.—The history in brief was as follows: The first sore came in October, 1896. The sore throat showed in December, and the eruption on the body and the ulcer in the pharynx came the next month. Some time during February, or only four months after the initial lesion, he began to have pain in the muscles of the neck and increasing stiffness. Immediately on the appearance of the chancre he began treatment, but it had little or no effect. He was in a pitiable condition when I first saw him, July 17, 1897. For six weeks he slept in a chair, as the pain on turning, or rising to expectorate, was intense. It was necessary to give him morphin frequently to ease his suffering. He came to the office daily for treatment of the ulcer. Improvement began to be noticeable in about ten days, and continued, gradually but slowly, until full recovery.

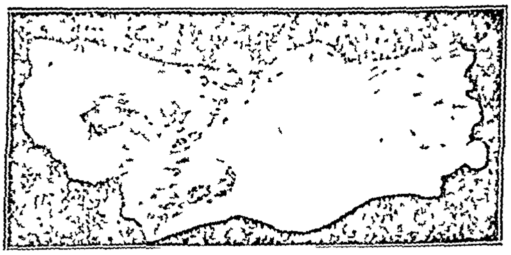

Fig 2.—Same, posterior view.

Treatment.—He was put on daily inunctions of mercurial ointment and increasing doses of protoiodid, beginning with ¼ grain, after each meal, and reaching finally as high as 2½ grains at a dose. With this was given a bitter tonic, with essence of pepsin. The food consisted principally of milk, egg-nog and soft-boiled eggs. Locally, the ulcer was washed out daily with an alkaline spray and peroxid, and filled with a mixture of papain and iodoform.

The extreme pain lessened and then disappeared, but the limitation of motion continued. Except for a rocking motion of the head on the condyles, all turning seemed to be from the waist. The ulcer did not entirely heal, and it was apparent that there was dead bone at the bottom. This was allowed to separate of itself, which it did early in October, and very much to my surprise, I found that nearly the entire anterior arch of the atlas had come away.

A few days later the patient told me that he hawked up a small piece of bone, shaped like a finger nail, smooth on the one side and rough on the other. This was doubtless the articular facet from the anterior face of the pin of the axis. This scale of bone was, unfortunately, not preserved.

The illustrations show the front and back views of the piece of the atlas exfoliated and are about one-half larger than the original.

Course.—After the sloughing off of the piece of bone, the ulcer quickly healed, and the patient, in a few weeks, was able to do light work. For some months afterward, a sharp pain warned him not to move the head too far backward, and the motion of rotation was limited about one-half.

A marked depression existed in the throat at the site of the injury, and the finger there could not detect any motion whatever between the atlas and axis.

The extent of rotation has increased somewhat during the past years, probably from increased mobility of the cervical spine, and, except for the slight stiffness of the neck, the patient shows no symptoms of his former trouble.

Other Cases.—I find recorded in the literature some eighty cases of caries and necrosis of the atlas or axis, the vast proportion being evidently tubercular. With but few exceptions, they ended fatally, and nearly all of those who survived were paralyzed in greater or less degree. I was able to find only five cases[1] of syphilitic exfoliation of parts of these bones, one reported from Germany, three from Great Britain, and one from this country. All recovered. Doubtless a good many other cases of this kind have occurred, which have not been reported, for this is a common place for a pharyngeal ulcer, and deep ulcers from syphilis are extremely frequent.

In the other five cases found, as well as in my own, there were no signs of inflammatory trouble of the medulla, despite the nearness of the disease to this vital point.

70 State Street.

ABDOMINAL PAIN AND PNEUMONIA.

G. H. SCOTT, M.D.
Assistant Surgeon, U. S. A.
BULAN, SORSOGON PROVINCE, P. I.

In connection with the instructive paper by Dr. Herrick in The Journal of the American Medical Association on "Abdominal Pain in Pleurisy and Pneumonia," I report the following case:

The patient, a native female, single, aged 20, of previous good health, suddenly was seized about 10 a. m. with a violent chill, followed by very severe pain in the umbilical region. This lasted for about an hour. About 5 p. m. the pain returned, and she had a sensation of "burning up," as she expressed it. I saw the patient for the first time about 9 p. m. The abdominal pain seemed to radiate downward and laterally from the umbilicus, but did not extend above that point. It was of a dull, aching character, although the first paroxysm had been of a sharp, stabbing nature. No evidence of tenderness was found, and there was no rigidity or tympany. Bowel movements had been natural. The temperature was 100, pulse 80, full and strong. Examination of the chest was negative, except that there was hurried breathing and a few coarse râles. Heart was normal.

The next morning, after a sleepless night due to the abdominal pain, which was but partially relieved by morphin, gr. ¼, the patient had a violent paroxysm of coughing without expectoration, which lasted about half an hour. When I saw her a little later, there was some cessation of pain, the temperature was 100, pulse 92, with no more physical signs of chest disease than on the previous evening. I decided the condition was one of acute bronchitis, but could not account for the abdominal pain. That evening the condition was precisely as in the morning, except that pain was less (no more morphin given) and a slight, dry cough had developed. Patient slept well that night. On the morning of the third day the pain had ceased entirely, the cough was slight, but now was accompanied with mucopurulent expectoration. On auscultation, numerous fine crepitant râles were heard, but the breath sounds, while increased in number, were otherwise normal. Temperature 100, pulse 90, respiration 22. Patient felt much better, but toward evening the abdominal pain returned in greater intensity after a slight but natural movement of the bowels, and vomiting set in, again directing my attention to the abdomen. There was, however, no evidence of abdominal disease. There were no additional signs in the chest, although the cough and mucopurulent expectoration had greatly increased. Patient passed a good night, due probably to a ¼ gr. of morphin, necessitated by the severity of pain.

The next morning (fourth day of illness) pain and vomiting had ceased, and physical examination gave all the signs of an acute lobar pneumonia, involving the upper lobe of the right lung, and for the first time the patient complained of pain and constriction in the chest and dyspnea, and curiously enough the pain was wholly on the left side, which remained normal. Temperature was now 102, pulse 90, full and strong, respiration 28.

The patient then ran a typical course of pneumonia, the temperature falling by crisis on the twelfth day after the original onset of illness. On the second day of the pneumonic process, the abdominal pain returned, and continued in a slight degree during the entire course of the disease, subsiding entirely at the crisis, never to recur. There were no other abdominal symptoms nor any abdominal signs.

Convalescence was rapid and perfect. However, four weeks after I had discharged the patient as cured, edema and pain of the extremities suddenly developed, and death resulted in eighteen days from acute beri beri, which is so common among the native population. The attack of beri beri evidently bore no relation to the pneumonia for three weeks after discharge the patient was well and strong as ever and enjoying perfect health.

New Instrument.

A NEEDLE TO CARRY THE McGRAW ELASTIC LIGATURE.

JOHN M. BELL, M.D.
DETROIT.

The accompanying illustrations show a needle which I have devised to carry the McGraw elastic ligature. The needle is one solid piece of steel, with a slot in the end, into which the ligature is placed after being put on the stretch.

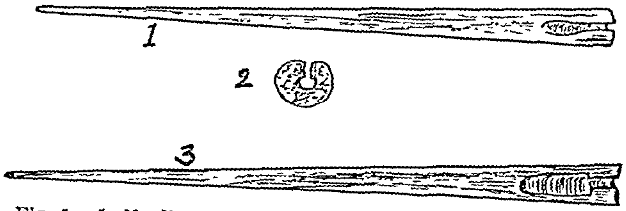

Fig. 1.—1, Needle to carry elastic ligature; 2, end view; 3, sectional view.

When relaxed the end of the ligature which lies in the groove expands sufficiently to hold it in place when being drawn into the stomach or intestinal wall. A large ligature can be used with a small needle by clipping a small piece from the side of the ligature near the end.

Alcohol.—Valentino has shown in the *Revue de Méd.* that the toxic effects of alcohol are due in part to its dehydrating power, as previously asserted by Dubois; the staggering gait to the toxic power of alcohol proper and the coma to the absorption of water from the nerve tissues.

THE BODY-WEIGHT CURVE IN CHRONIC DISEASES.

The significance of the temperature curve for diagnostic, prognostic and therapeutic purposes in the acute and subacute diseases, is generally recognized. The clinical thermometer is diligently used by every practicing physician, by the trained nurse, and often by the laity independently of physician or nurse.

It was Gerhardt who first emphasized the fact that the body-weight curve is as important for the study of the nature, progress and treatment of the chronic diseases as the temperature curve is for the study of the more acute maladies. Nothing is more true than Gerhardt's statement, and yet it is but rarely in hospital or private practice that the advantages of keeping accurately a body-weight record over a longer period are fully appreciated. Many elaborate methods have been devised for studying the "total metabolism" in health and in disease. The methods are extremely difficult in application; the composition of the food and its energy-value in calories has to be determined; the relation of the incoming to the outgoing nitrogen has to be studied; the amount of carbon burned and of oxygen absorbed must be ascertained. As a substitute for these metabolic analyses, the procedure of direct calorimetry may be resorted to in the manner so well carried out by Atwater in this country. The more rapid and less circumstantial method of studying oxidation processes introduced by Zuntz and Geppert, in which the so-called "respiratory-quotient" is determined while the patient is fasting and at rest, while it has yielded results of scientific value concerning the temporary effects of work, food and drugs on metabolism. can yield us no reliable information regarding the total metabolism over a longer period than a few hours, or, if any, only clues as to the coarsest kind of deviation from the metabolic normal.

For a complete judgment regarding the measure of the oxidation processes in the body and the questions as to whether the total metabolism is pathologically high or low, and as to whether a given regimen is sufficient, is overabundant or is deficient, it is necessary to keep the patient for at least twenty-four hours at a time in a respiratory apparatus or a calorimeter, and, beside carefully analyzing the food, to make quantitative estimations of the nitrogen and carbon given off in the urine and feces. It is obvious that the necessary data for such a judgment could be obtained only in hospitals with outfits especially adapted for the purpose (like that of Professor Jaquet's in Basel), and that in ordinary hospital and private practice such things can not be thought of.

These complete experiments, desirable as they are for rigid scientific investigations, are totally impracticable, and, beside, wholly unnecessary in general practice, where, as a matter of fact, an approximate estimation of the metabolic relations is all, in the present state of our knowledge, that the physician needs in this connection to guide him in advising his patient; and such an approximate estimation, provided the kind and amount of food be known, is afforded by the simple observation of the body weight over a certain period.

In studying the body-weight curve, as Fr. Müller[1] has emphasized, certain details must be considered, such as the temporary changes in the content of the bladder and intestine, and, especially, the variations in the amount of water in the body which take place when a patient changes from one kind of diet to another, or in fever, in profuse sweating, in diminished water-absorption (as in stenosis of the esophagus or pylorus) and in the accumulation or absorption of exudates and edemas. Taking these things into account, the observation for a considerable length of time of the body-weight curve is one of the best means we have of judging the metabolic activities of the body. When the patient takes an ordinary diet, it is easy to estimate the nutritional value (i. e., to determine the energy-value in calories) of the food eaten, with sufficient accuracy for clinical purposes, by referring to Schwenkenbecher's tables.[2] A healthy resting man needs daily 33 calories per kilo of body weight; if his occupation is sedentary, 35 calories; if moderately active, 41, and if involving hard labor, about 48.

Not infrequently in people who are losing flesh without apparent cause, an estimation of the energy-value of the food taken in reveals the fact that, though the patients believe they are taking enough food and of the right kind, they are really not doing so; in such cases a readjustment of the diet usually brings the body-weight curve back to normal. Or, again, when on a well-arranged diet, fully sufficient in energy-value for the maintenance of the body weight of a healthy individual, a patient continues to lose flesh, a consuming disease of some kind, even when no other symptoms are obvious, may be safely predicated. A man with latent tuberculosis, even in the afebrile stage, may lose weight on a diet, the energy-value of which exceeds 50 calories per kilo. In locomotor ataxia and certain other chronic affections, the patients usually remain thin and pale, in spite of an abundant food supply, while in Basedow's disease, a patient with ravenous appetite, consuming food with an energy-value of from 60 to 70 calories per kilo of body weight, may progressively emaciate.

DEMONSTRATION OF TUBERCLE BACILLI IN FLUIDS.

Inoculation experiments to prove the tuberculous or non-tuberculous character of fluids which contain bacilli in too small numbers to be detected by the microscope, have always been only partially satisfactory, because of the length of time needed before a result can be obtained. Several weeks must elapse before the development or non-development of tuberculosis in the inoculated animal decides the question. Now Marmorek[1] announces the discovery of a new method which he asserts will give prompt results and enable one to prove the tuberculous character of a fluid within a few hours' time. The value of such a method to clinicians is obvious, and great interest attaches to this statement. Marmorek's explanation of the tuberculin reaction differs from that usually accepted. It is generally held that this reaction will take place only in an organism in which the histologic lesions of tuberculosis are present, and, therefore, not until some time has elapsed since the infection has occurred. Marmorek, however, holds that the tuberculin reaction takes place between the tubercle bacilli and the tuberculin; the latter as it comes in contact with the bacilli causes them to secrete a toxin which gives rise to the fever and other symptoms which make up the tuberculin reaction. The presence of tubercles is not necessary for this reaction, and, therefore, it should be possible to bring it about immediately after an injection of bacilli without waiting until they have set up structural changes in the organism. Accordingly, Marmorek has found that the characteristic febrile reaction can be obtained by the injection of tuberculin a few minutes after the injection of a small dose of tubercle bacilli. One cubic centimeter of a slightly opalescent suspension of tubercle bacilli is injected under the skin of a guinea-pig, and then after the lapse of from fifteen to twenty minutes it is followed by the injection of 0.3 c.c. of tuberculin—a dose too small to have any effect on a control animal. The temperature of the animal begins to rise almost immediately, and by five hours it has reached 40 C., or even higher. If a stronger suspension of bacilli is used, the animal may die of intoxication in a few days; the same result may be obtained if a larger dose of tuberculin is used. The interval between the administration of the bacilli and the tuberculin should be not less than fifteen minutes nor more than an hour and a half. After this time the reaction grows more and more feeble, and by twenty hours it fails altogether, owing, as Marmorek thinks, to the fact that the leucocytes have by this time incorporated the bacilli, and act as a barrier between them and the tuberculin. The appearance of the tuberculin reaction at a much later period, as in the usual procedure, Marmorek explains by supposing that the bacilli have become free again as a result of the disintegration of the leucocytes.

In his most recent publication[2] he states that it is necessary to modify slightly the above method when the number of bacilli in the fluid injected is extremely small, as may often be the case in pleuritic or peritoneal effusion, cerebrospinal fluid, sputum, urine, milk, etc. In such cases it is necessary to inject the tuberculin directly into the substance of the cerebrum. Half an hour after the subcutaneous injection of the suspected fluid the skull of the guinea-pig is trephined and one-eightieth of a drop of tuberculin is injected into the brain. The temperature then rises two or more degrees centigrade, while that of a control animal—which has received the intracerebral dose only—rises not more than one and four-tenths degrees, usually much less. Marmorek considers this method simple, positive in its results, and of great value in demonstrating the tuberculous character of fluids, which, by the older method, could not be demonstrated until after the lapse of several weeks.

A much more cautious and less optimistic statement is made by Nattan-Larrier,[3] who has been working in the same field in Dieulafoy's laboratory since 1900. He also finds that it is unnecessary to wait for the development of the anatomic lesions of tuberculosis before obtaining the tuberculin reaction, but his method is not as rapid as that of Marmorek. He has obtained his best results by allowing four to six days to elapse between the injection of the suspected fluid and the injection of tuberculin. Nattan-Larrier uses pregnant guinea-pigs, and makes the injection into the fibrous tissue around the mammary gland. His results were all carefully controlled by inoculation experiments, and his statements are cautious and carry conviction to the reader. While believing that this method may be used to demonstrate the presence of tubercle bacilli in a fluid long before the usual inoculation experiments could do so, Nattan-Larrier utters a warning as to its employment. The fact that the diagnosis must depend entirely on the rise of temperature in the animal makes it a delicate and doubtful experiment unless every possible precaution is used. The temperature of the guinea-pig is naturally variable, and it is, therefore, necessary to ascertain the normal variations of each animal before use, to employ a very sensitive thermometer, and to insert it into the anus at the same depth each time, otherwise errors may easily arise. As we have already seen, there is a difference of only six-tenths of a degree between the maximum temperature given by Marmorek for a non-tuberculous reaction—one and four-tenths degrees centigrade—and the minimum temperature for a tuberculous one—two degrees centigrade.

We shall await with great interest the further publications on this subject promised by these experimenters. A sure and rapid method for the demonstration of tubercle bacilli, which are too few to be detected by the microscope, will be an immense aid to the diagnostician.

SUGAR METABOLISM THEORIES.

The number of theories advanced to explain a phenomenon or process in nature is often inversely proportioned to our understanding of that phenomenon. This is especially true in regard to the mechanism of sugar metabolism in the body, for we find here a long list of theories to explain it, while none of them is entirely satisfactory, and new ones are still being added. As early as 1886 it was observed that there are changes in the pancreas of patients who succumb to diabetes; and these observations led investigators to believe that the pancreas in some way regulates the consumption of sugar in the body. This view received a strong support in 1890 by the classical experiments of v. Mering and Minkowski. They removed the pancreas from dogs, and found that this operation is followed by marked glycosuria and other symptoms of diabetes mellitus. A partial extirpation of the gland was followed by a mild form of glycosuria, which, however, later passed into a severe form. On the other hand, de Renzi and Reale observed no symptoms of diabetes after extirpation of the pancreas; but their observations led them to believe that the sugar metabolism is controlled not only by the pancreas, but also by the salivary glands and the duodenum. This view they found substantiated by the fact that the removal of these organs was followed by glycosuria.

In view of the fact that a slight injury to the floor of the fourth ventricle of the brain, a brain tumor or concussion of the brain, often produce glycosuria, it has been held by some that the glycosuria following extirpation of the pancreas is not due to the loss of this gland, but to injury, during the operation. of the celiac plexus and other nerves of that region. The metabolism of sugar would, therefore, be under the direct control of the nervous system. A. and E. Cavazzani have demonstrated degenerative changes in the celiac plexus and in the nerves accompanying the hepatic artery, after removal of the pancreas, but it has been proven that these changes are not the cause of the glycosuria. If a portion of the pancreas of a dog is removed and transplanted under the skin, and the remaining portion of the gland then removed by a later operation, no glycosuria is produced by this operation, although the injury to the nerves is fully as great as when the pancreas is removed by one operation. The removal of the transplanted portion of the pancreas by a third operation is followed by glycosuria. These facts show that the pancreas in some way regulates the consumption of sugar, but how this is done is by no means clear.

Lepine then advanced the theory that the pancreas has an internal secretion of the nature of a glycolytic ferment, and that this secretion passes through the thoracic duct into the blood, where it is found in close relation to the white corpuscles. He asserted that he had found this ferment in diminished quantities in diabetic patients and in animals which had the pancreas removed by operation. This theory was vigorously attacked from all sides, and Arthus showed that the sugar in the blood, held in a vessel between two ligatures, does not disappear. If this observation is correct, there can be no glycolytic ferment in the blood. Many other objections to this theory have been brought forward, and Lepine himself has discarded it for a new one, according to which the pancreas (independent of an internal secretion) is supposed to destroy substances which prevent glycolysis in the tissues. It is still very widely held, however, that the pancreas has an internal secretion of the nature of a glycolytic ferment. Opie has shown that the islands of Langerhans are the chief structures concerned in human diabetes, and it may now be conjectured that they have an internal secretion which is necessary for the metabolism of sugar. Very recently Cohnheim[1] has shown that although extracts of either pancreas or muscle made by grinding up the frozen tissues and expressing the juices with a powerful press, are practically without glycolytic properties, yet a mixture of the two is capable of rapidly destroying relatively large quantities of sugar. He found also that blood serum, when mixed with the juices obtained from the pancreas and muscles, has an anti-glycolytic action, which would indicate that the oxidation of sugar does not take place in the blood but in the muscles, where it can furnish both heat and energy. It seems, then, that the islands of Langerhans of the pancreas have a secretion which, when mixed with a substance present in the muscles, forms a ferment that has the power of rapidly destroying sugar.

Cohnheim's views are, however, disputed by Blumenthal,[2] who claims to have made, from various organs, extracts which are capable of destroying large quantities of sugar. He states also that a dog can utilize sugar after total removal of the pancreas. Blumenthal favors the view that all tissues contain a glycolytic ferment, and that the liver may be of special importance in the oxidation of sugar. He admits, however, that a mixture of the extracts of pancreas and muscle destroys larger quantities of sugar than either extract alone, and it would seem, therefore, that Cohnheim's view is liable to be slightly modified as new facts are being discovered. In 1902, Croftan[3] published certain observations, from which it appeared that the destruction of sugar is promoted by the combined action of pancreas and albuminoid bodies, such as hemoglobin, which consequently would have to be wholly removed from the tissues employed in experiments like those mentioned in the foregoing to exclude definitely its action.

A TYPHOID FEVER CENTER.

Attention has been recently directed once more to the remarkable prevalence of typhoid fever in Pittsburg,

---

[1] See The Journal A. M. A., Dec. 12, 1903, p. 1480.

[2] Deutsche med. Woch., Dec. 17, 1903.

[3] Phila. Med. Jour., 1902, p. 143; Am. Jour. Med. Sc., 1902, p. 669.

Pa., by the discussion in regard to filtration which has been carried on during several months by the public press of that city. When one of the leading newspapers of Pittsburg is moved to print an editorial under the caption "Our Typhoid Pre-eminence," it is evident that the situation must be recognized as one worthy of concern. Just how serious the conditions are may be gathered from the fact that the typhoid fever death-rate of Pittsburg has for some years outranked that of any other large American city. It is stated that in 1903 there were 473 deaths in Pittsburg from typhoid fever, a figure that would signify a death-rate more than four times as high as that in the city of Chicago during the same period. In the census year 1900 Pittsburg recorded 465 deaths from typhoid, or a death-rate of 14.49, as compared with a death-rate in the same year of 1.81 for New York, 1.98 for Chicago, 2.55 for Boston, and 3.47 for Philadelphia. The report of the Filtration Commission of Pittsburg, published in 1899, shows that this pre-eminence is not a new distinction, but that there has been for many years a marked and deplorable excess of typhoid fever in the city.

These facts are by no means unknown to the inhabitants of Pittsburg. A movement to purify the water supply was set on foot some years ago, but the plan has failed of full fruition. It is now hoped that the arrangements for a comprehensive filtration system, which have so long been allowed to hang fire, will soon be put into execution. Since it seems to be true that the cities of Chicago and Philadelphia, long signal offenders in the matter of a pure water supply, are about to lose their unfortunate pre-eminence, Chicago, through the completion of its system of intercepting sewers, and Philadelphia, through the construction of an admirable sand filter plant, it is hardly to be supposed that a city so wealthy and ambitious as Pittsburg will allow itself to assume a rôle of such unenviable notoriety.

There is one feature in this connection which we believe has not received sufficient attention, namely, the intimate sanitary interdependence of communities geographically and commercially related. The section of Western Pennsylvania around Pittsburg and Allegheny has long been known to be grievously infested with typhoid fever. The recent outbreaks at Butler and Kittaning are still fresh in the minds of our readers. It does not seem unfair to assume that the extended diffusion of typhoid fever throughout this region must be laid in large part at the door of the city of Pittsburg. It is clearly impossible to calculate exactly how many persons may have contracted typhoid fever during visits to the metropolis of Western Pennsylvania, and have returned to their homes to furnish the material for fresh outbreaks. It needs no argument to show that the infected water supply of a large city may diffuse its baneful influence far beyond the limits of the community immediately responsible for its existence, and may serve to light up new foci of infection in scores of innocent towns and hamlets. The exceedingly mischievous character of a highly infected water supply in any great center of population and commerce can hardly be overestimated. The whole country is directly concerned in having the situation at such infected centers corrected promptly and effectively. The ever-widening circle of infection that spreads out from such a focus of typhoid fever as that at Pittsburg menaces the health of even far distant communities. It is almost a matter of national importance.

CONCERNING MERCURIAL EXANTHEMATA AND IDIOSYNCRASY TO MERCURY.

Considering the fact that, if all forms of the drug are included, mercury is one of the most frequently used medicaments in the Pharmacopeia, it is of great importance to recognize the skin lesions produced by it. It is only recently that we have appreciated that not only the use of mercury by the skin, but also its internal and subcutaneous administration, may lead to cutaneous lesions which closely resemble certain of the exanthemata or specific skin diseases.

In a recent article, Tomasczewski[1] reviews the question of the mercurial exanthemata, illustrating his points by cases of his own, and by others cited from the literature. His views regarding the importance of certain conditions underlying mercurial skin lesions are somewhat at variance with general opinion. He points out that the method of application of the mercury is of minor importance, and that exanthemata may be produced by the oral, hypodermic or dermic administration of the drug. He qualifies this statement by admitting that in applying the drug externally more of it is necessarily brought into contact with the skin than is the case when the oral or subcutaneous methods are used. It has been generally held heretofore that the internal administration of mercury did not cause exanthemata. In considering individual idiosyncrasies he follows Jadassohn in holding that there are two classes of individuals subject to toxic eruptions—those who have a general hypersensitiveness of the skin, in whom any irritating substance will produce skin lesions, and those who have a special or specific hypersensitiveness to certain drugs which are not necessarily of an irritating nature.

In this paper Tomasczewski discusses only the true mercurial exanthemata, which are to be distinguished from the ordinary acne mercurialis of the hairy surfaces, and the fugitive mercurial dermatitis most common in the axillæ and groins, both of which are associated with the local application of the drug. The true mercurial exanthem may occur after the administration of the drug in any form. The eruption in these cases is varied, and no less than seven types may occur. Tomasczewski cites cases resembling measles, cases resembling scarlet fever, those resembling purpura hemorrhagica, those resembling erysipelas, erythematous and urticarial eruptions, and eruptions simulating pemphigus vulgaris. The urticarial eruptions and those resembling scarlet fever are fairly common, the other forms rather rare. In the form simulating measles, all of the symptoms and signs of the disease, including a diazo-reaction in the urine, may be present, and scarlet fever may be mimicked as closely. The pemphigoid form is most difficult of diagnosis, but is infrequent. In discussing the diagnosis of mercurial skin lesions in general, the author lays stress on the tendency to extensive desquamation, and the peculiar violet-red color of the lesions. Needless to say, the history of the use of mercury, and the fact that recovery follows the discontinuance of the drug, is of great importance, as is also a recurrence of the lesions on the resumption of the mercury.

---

THE BUTLER EPIDEMIC.

With the closing of the emergency hospital February 25, the typhoid epidemic at Butler, Pa., may be fairly said to have come to an end. The total number of cases during the outbreak has been about 1,364, and the number of deaths 115. A noteworthy and deplorable feature of the epidemic has been the infection of some twenty of the nurses, amounting to nearly 10 per cent of the number employed.

THE ANTI-SPITTING CRUSADE.

At present there seems to be a revival of the anti-spitting crusade, and we hope it will be more effective and permanent in its results than have been previous endeavors along this line. In a number of cities active measures have been taken, and persons have been surprised at their arrest for what they considered the exercise of a natural right. The danger from sputa is a real one, though it may sometimes be exaggerated, but there is enough otherwise objectionable in the habit of itself to make it condemnable. As it has been permitted in the past, no one can question the fact of its having been a nuisance. There is, of course, a certain hardship to persons who have to expectorate, and the habit of carrying pocket cuspidors will be very slowly acquired, and perhaps never will become a general one. But the disgusting practice of spitting on sidewalks, in street cars and on floors generally, is not an excusable one under any circumstances, not even on the ground of necessity.

THE EXPLOSION OF CURRENT BELIEFS.

One of the results of the ceaseless investigation which characterizes the medical world of the present, is the retesting of many of the theories, which, on account of their age, or their apparent rationality, have almost assumed the finality of facts. Most of us can remember the time when the idea that appendicitis was generally caused by foreign bodies was current, an idea which still exists in the minds of most of the laity. And now comes an article by Prettin and Leibkind[1] which shatters our current belief regarding the prevalence of emphysema in glass blowers. If ever a theory seemed rational and well grounded, that which regarded wind-instrument players and glass blowers as particularly prone to emphysema would seem to have been one. The examination of two hundred and eighteen glass blowers by the authors mentioned showed only five cases of emphysema, a result which is decidedly destructive to the current belief on this point. Fischer's article[2] of two years ago showed almost identical results so far as wind-instrument players were concerned, as he found that in five hundred military musicians there was no case of emphysema, even in individuals over fifty. Thus another idol is shattered.

MEDICAL INFLUENCE AND JAPAN'S DEVELOPMENT.

In a recent interview, a rather prominent Japanese resident of New York, Dr. Takamine, whose name is well known in medicine in connection with adrenalin, taka-diastase and other preparations, is reported to have given his opinion as to the methods by which Japan was opened to the world and so successfully induced to adopt the methods of western civilization. According to him, even under the old régime when intercourse with outsiders, save in a limited way with the Dutch, was forbidden, western medicine had made its way into Japan and was exerting its influence, not only in a sanitary way, but as a general civic factor introducing occidental methods of thought and life. He points out that the personnel of the ministerial cabinets that have existed under the mikado's rule in Japan in the last thirty years, or thereabouts, have all been more or less influenced by western medicine; a very large proportion of their members, 40 to 60 per cent., were either medical men or sons of medical men, or else had been in direct contact with medical practitioners of the west. Marquis Ito, the "grand old man" of Japan, came from a family, almost every man of which has been connected with the medical profession. As the *Chicago Tribune* says, this showing is equally complimentary to the vigor of medical science and to the intelligence of Japan. It is possible that Dr. Takamine overestimates the influence of medicine in the progress of his country, but that it has been an important factor seems evident enough from the facts he adduces.

THE NEW YORK STATE MEDICAL ASSOCIATION.

Step by step the details are being completed in making the medical profession of New York one united body, which shall press on to greater achievements for the honor and triumph of medicine. The change is a great one, and perhaps—as the details have worked themselves out—it becomes more of a change to the members of the New York State Medical Association than to those of the Medical Society of the State of New York. The latter body has approved of the plan of union, and its county societies are rapidly following its lead and approving the action. On the 21st of this month the association will meet to ratify the action. This appears to some, and no doubt is in truth from one point of view, a termination of the career of the New York State Medical Association. Its name ceases, and its separate existence ends, but in a far broader and more practical sense it now enters into a new life. The New York State Medical Association has an enviable history of over twenty years which requires no apology. Organized through staunch loyalty to the national body at a time when discord rent the New York profession, it has maintained the principles of the American Medical Association these years without discredit. Through circumstances over which there appears to be almost universal congratulation, the sources of the discord have been removed. Having served faithfully as the representative of a portion of the medical profession of the State of New York, the association now steps out into the wider sphere and represents the whole profession. By remarkable liberality and courtesy, it relinquishes its own name to take another, but it is the spirit of the association which lives on. It is a noble act, one fitting to close such a twenty years' record as is now about to be handed down to history as a finished product. It is not easy to surrender the traditions of even twenty years without some pangs, and it is only natural that the members of the association—some of them more than others—feel that the sacrifice they make in this reunion is very great. It is a feeling that all will respect; but the purposes and ends of all this labor seem thus far to triumph over lesser considerations. The spirit of loyalty and of sacrifice shown by the members of the association is one of the grandest legacies which they can bequeath to the new organization. The medical profession of the whole country owes its thanks to the members of the New York State Medical Association, a body which will always have its honored place, and none the less for what sacrifice it has made, in the medical history of our country.

HEALTH BOARDS AND POLITICS.

Boards and departments of health are generally supposed to be institutions for the protection of the public against disease and not merely political machines. This fact is recognized in some municipalities, but unfortunately not in all, as some recent experiences demonstrate. The San Francisco Board of Health, during the Gage administration in California, was a body of officials in whom the people of the country had confidence as a defense against a possible epidemic of plague and its extension from the focus that existed in the city under its sanitary control. Now matters have changed; the present mayor has at last succeeded in changing the whole personnel of the board, supplanting the former members by those who can be expected to be more subservient to his commands regardless of their duty as conservators of the public health. As an evidence of what they are willing to do at his behest, we have the general discharge of the tried employes of the former board, as shown up editorially in the February issue of the *Occidental Medical Times*. There were six cases of plague reported in San Francisco by the Public Health and Marine-Hospital Bulletin during February. The infection still exists in that city, but we have the assurance that a political partisan board, appointed in the place of the one discharged because it did its duty, has now the responsibility of the protection that the city can afford itself and the country against the scourge. Is it a legitimate assumption that they will efficiently perform the duty for the doing of which their predecessors were ousted? This is not a matter that concerns San Francisco alone; it is one for the whole country to consider. If we had to depend on the San Francisco Board of Health, appointed by and presumably in full sympathy with a mayor whose whole object and aim has been apparently to deny the existence of the plague and obstruct all efforts against its spread, we should be in a bad way indeed. Another instance of the removal of a tried official for political reasons is noted in another of our contemporaries, when the principal officer of a board of health was removed for the reason, as given by one of the politicians, that "this plum should be passed on." We might multiply examples of this sort of malfeasance in office by politicians prostituting charitable institutions to the demands of party politics and unscrupulous partisans *ad nauseam*, but it is unnecessary. That such things can occur is one of the disgraces of our times, and we would be remiss in our duty if we neglected to utter our protest. It is not the individual who suffers in these cases; it is the people as a whole, and that they do not suffer more is due to the unthanked and often gratuitous efforts of honest members of our profession to counteract the evils that follow.

SANITARY RELATIONS OF THE PANAMA CANAL.

Panama Canal problems are numerous enough, but one complicates them all, namely, the question of sanitation. It was one of the arguments used in favor of the Nicaragua route that it is comparatively healthful, and it certainly has no such record as that of the Panama isthmus. It was said that when the railroad was built across the isthmus every tie cost a human life, and the French Canal Company, which our government proposes to succeed, had a history not much more encouraging as regards the healthfulness of the work. There is no doubt that much of the mortality that went with the work of the past can be avoided in the future; that is, if the sanitary arrangements be under the absolute control of some one who understands what preventive measures are needed, and who will see that those measures are adopted. Our knowledge of tropical disorders has greatly advanced within the past few years, and the two most formidable ones to be fought on the isthmus—malaria and yellow fever—are practically under medical control. To a very great extent, the same is true of the other less serious tropical disorders; nearly all are parasitic, and may be avoided by the observance of due sanitary precautions. The isthmus itself is not so essentially unhealthy for a tropical region; the greater part of the work is in a region several hundred feet above the sea, and with good natural drainage, where the conditions are certainly as good as could be looked for in any non-mountainous tropical country subject to the rainfall that occurs at Panama. The immediate vicinity of the Caribbean terminus of the canal is low and marshy and furnishes perhaps the most serious problem of sanitation of the whole route. The region near Panama is also low but drier and more easily brought under sanitary control. In both these regions a considerable portion of the work is already done, and what remains is but a very small fraction of the whole; the bulk of the excavation, therefore, is in the higher and healthier uplands. Thus, so far as the natural conditions are concerned, there is reason to hope for a decided improvement on the record of the past. It is in the policing and control of the personnel and the enforcement of sanitary regulations, both in the canal force and among the native population, that we must look for most aid in reducing the excessive mortality of the past. With our experience in Cuba and the Philippines we ought to be better able than heretofore to satisfactorily meet the conditions, especially if the digging the canal is under military control that was elsewhere so successful. We can not expect to escape a certain amount of mortality and disability from diseases incident to a tropical climate, but there is reasonable hope that sanitary measures will reduce them to a minimum.

THE CIRCULATING MEDICAL ARTICLE.

Some months ago we commented[1] on the remarkable performance of one Plympton of Brooklyn, who succeeded in having an article on "Septicemia and the Curette" published in over a score of journals. Plympton now has a rival in this sort of notoriety. We recently were offered, by Dr. H. John Stewart or, according to some papers, John H. Stewart, an article entitled "The Finsen Light Cure"—a nicely worded advertisement for a Finsen light cure institute in Chicago. We did not accept, but we have been interested to note that the bait has been taken in different parts of the country, for already twenty journals have published the article as original. It is interesting to note that this Finsen light company is following up the free advertising accorded it in the medical journals by large displays in street cars and lay magazines, and by sending out circulars in which its confidence in the panacean qualities of the light is touching and sublime. The *Memphis Medical Monthly* notices that the article referred to has appeared in several journals, and says:

> While we can not blame an author for wishing to secure wide circulation for an article, and can see no harm in simultaneously securing publication of a deserving contribution in a local medical journal and in one of the larger weeklies, yet we must deprecate the practice which we see occasionally indulged in, as did this author. It is not that the medical journals care very much about this imposition, but it would seem to indicate that the author's fund of information is too limited to permit his adding greatly to the stock of medical literature, so he must make the most of what little he does write, however indifferent it may be in quality.

Apparently this editor had not discovered the gentleman of color in the woodpile, but the editor of the *Medical Council* had his eyes open. Under the heading of "Sold Again," he comments on the light-cure article thus:

> The same article was sent to us for publication, but we saw the nicely disguised advertisement contained in it, and suspected that it was another attempt to palm off a "multiple copy" on the medical journals as original.

The editor of the *Medical World*, when he received his manuscript of this remarkable publication, "had a suspicion that all was not straight," so he wrote to the author asking if he had sent or intended to send the article to any other journal for publication. He says he received the following letter in reply:

> You need not hesitate about printing this article, for the same article will not appear in any other journal, you having received the original and the carbon copy being still in my possession.

Perhaps it would be charitable to say that the author's typewriter answered this letter inadvertently without referring it to him. The editor of the *Medical World* apologizes to the readers of that publication for having been misled into thus imposing on them by printing the article. He gives the names of nine other journals which printed it. We had thought of doing the same with the twenty, but we forbear. Although we are ourselves by no means infallible, we may be allowed to say that in view of the fact that among the journals which have published this article were a number of the better journals of the country and three weeklies, the comment with which the editor of the *Medical Council* concludes his remarks appears to us exceedingly appropriate: "Doctors, we beseech you to examine more closely manuscripts submitted to you."

Medical News.

ILLINOIS.

Diphtheria.—Several deaths are reported to have occurred at Marquette, a village near Spring Valley.——Schools at Gilman have been closed on account of the prevalence of the disease.

Heavy February Mortality and Morbidity.—Deaths in Springfield numbered 96 for February, 60 more than for the corresponding month of last year. In February, 1903, there were 12 cases of scarlet fever, with no deaths; in February, 1904, 51 cases and 2 deaths; there were 5 cases of diphtheria and 2 deaths last month, and in the same month of 1903, 9 cases and one death; of smallpox 4 cases and one death were reported in February, 1903, while in February, 1904, only one case was reported.

Chicago.

Personal.—Drs. Herman A. White and G. Morgan Clarke have returned from Europe.——Dr. Lucy Waite has returned from Tahiti.

Assistant Superintendent Johnston Dies.—Colonel William James Johnston, a confederate veteran, and for many years assistant superintendent of St. Luke's Hospital, died March 1, from Bright's disease, aged 59.

The Week's Deaths.—The death rate for the week ended March 5 was equivalent to an annual mortality of 16.71 per 1,000. Pneumonia caused 165 of the 625 deaths; consumption, 54; heart diseases, 51, and violence, 38. The death rate for the corresponding week of 1903 was 16.45 per 1,000.

Crusade Against Spitting.—The anti-spitting ordinance is suffering its first enforcement. Many careless spitters have been arrested, and some have been fined. A few pleaded ignorance, and one of the pioneers in the anti-spitting movement is alleged to have been one of the first offenders arrested.

February Mortality.—Pneumonia caused 686 deaths; consumption, 278; heart diseases, 195; Bright's disease, 165; bronchitis, 141, and violence, 148, out of a total of 2,705 deaths, equivalent to an annual mortality of 17.92 per 1,000. This is a lower rate than for February, 1903, which was 18.30 per 1,000.

Pneumonia in Excess.—With 56 days of the pneumonia season to come, the prediction of the department of health that deaths from pneumonia would exceed 2,100, the estimated number is already passed. Up to March 5, a total of 2,186 deaths from the disease have been reported, and if the daily average be maintained, the number at the close of the season will be about 2,800, or one-third more than was estimated.

---

[1] The Journal A. M. A., Nov. 22, 1902, p. 1327.

Again in Trouble.—Dr. A. W. Van Bysterveld, a practitioner said to be unlicensed, who has two offices in Chicago and one in Grand Rapids, Mich., was shot in the leg, March 8, by the father of a patient, an epileptic girl, aged 15, whom he is said to have wronged. This is apparently the "miracle-worker" of the same name who was noted in The Journal of March 21, 1903, as having been fined $100 and costs, at Grand Rapids, for practicing medicine without a license.

Free Antitoxin For Poor.—The Chicago Department of Health, in its current bulletin, makes the following announcement:

> 1. Physicians may obtain antitoxin free from the antitoxin stations of the department for the gratis treatment of their charity cases.
>
> 2. Physicians may have their prescriptions for antitoxin to use in their paid practice filled by any antitoxin station at the following (present) prices:

No. 1 (1000 units)	$0.75
No. 2. (2000 units)	1.25
No. 3 (3000 units)	2.25

The physician obtaining free antitoxin receipts for it, and the receipt contains the following certificate:

> I hereby certify that the family of this patient is unable to pay for the antitoxin; that the case is urgent; that I am attending without fee and that I will report the termination of the case on the postal-card form of the Health Department furnished by the druggist.

All cases in which free antitoxin is furnished will be investigated by the Bureau of Charities, but the antitoxin will be furnished first; the investigation will follow.

MARYLAND.

Personal.—Dr. James Bond, Westminster, who has been in Europe for the past year, has returned home.

Bills Drafted and Offered.—Bills have been drafted for presentation to the legislature for the granting of a charter to the Washington County Hospital Association, Hagerstown, for an annual appropriation from the state of $6,000 to enable the county commissioners and mayor and council of Hagerstown to levy annually for certain sums for the support of the hospital. ——Appropriations are also asked from the state for the Baltimore Eye, Ear and Throat Hospital, $10,000 for the Hospital for Consumptives near Baltimore, instead of $2,000 annually as now, and the Franklin Square Hospital, Baltimore.——A bill has been offered in the legislature prohibiting the use of wood alcohol in compounding flavoring extracts.

Appeal for Library.—In reference to the bill introduced into the legislature for an appropriation of $100,000 for purchase of a lot and erection of a fireproof building for the library of the Medical and Chirurgical Faculty of Maryland, the committee in charge has issued a circular in which occurs the following:

> ' It has taken a great many years to get this library together, and its destruction by fire would be an irremediable loss to the entire people of the state as well as to the medical profession. The grounds on which we base an appeal are that the library is an educational factor of the greatest importance; that though vested in the state medical society, it is to all intents and purposes a public medical library, being accessible to all physicians of good standing and to all students of medicine. Should this library be destroyed no amount of money could replace it, for there are many valuable works now out of print and extremely important sets that can not be duplicated anywhere.

Baltimore.

Personal.—Dr. Thomas J. O'Donnell, resident physician of St. Joseph's Hospital, was operated on for appendicitis on March 3.

February Mortality.—The mortality in February was unusually large, pneumonia, la grippe and consumption predominating. There were 203 deaths from pneumonia, against 153 for last February, and 142 from tuberculosis, against 91 for last year. The total deaths were 1,024, as compared with 862 for 1903; 750 births were reported.

Heavy Mortality for Week.—The total deaths for the week ended March 5 reached the high figure of 302, which is 100 more than the corresponding week of last year. This is equivalent to a rate of 27.97 per 1,000, or separating whites and blacks, of 24 per 1,000 for whites and 49.52 per 1,000 for blacks; 75 died from pneumonia and 90 from other affections of the respiratory organs.

Literary Fire Losses.—Among losses by the Baltimore fire were the entire unsold remainder of Professor Ashby's work on gynecology, Dr. Hubert Richardson's work on the thyroid gland, which would have been out the following week, and the current number of *American Gynecology*. All these were in the printing and publishing establishment of Williams and Wilkins, which was entirely destroyed. Dr. Richardson fortunately has the proof of his work, and thus the arduous labors he expended on it through the past several years will not be entirely lost. The Johns Hopkins Press fortunately escaped.

Johns Hopkins Losses.—At the annual meeting of the Johns Hopkins Hospital trustees, held March 3, it was definitely announced that John D. Rockefeller had sent an agent to investigate the needs of the hospital. Nothing definite, however, in the way of an offer of assistance was made. The announcement was made that $60,000 of the annual income of the hospital had been cut off by the fire. This is the nearest approach that can be made at present to the loss; committees have been appointed to investigate the exact figure and also the insurance. Dr. Hurd, superintendent, stated that the needs of the institution had been presented to Mr. Rockefeller by Dr. William H. Welch. Sixty-four buildings belonging to the hospital were destroyed, on which only 80 per cent. of the total amount of insurance carried can be gotten. "There is a disposition on the part of the trustees," said Dr. Hurd, "to go ahead with the work of the hospital in spite of the loss incurred." Judge Henry D. Harlan was re-elected president of the board.

MASSACHUSETTS.

Personal.—Dr. A. Everett Austin, Boston, of the faculty of Tufts College Medical School, will spend the next seven months in study in Ludwig's bio-chemical laboratory at Vienna.

Thousands for Crippled Children.—The fair held at Hotel Somerset, Boston, by the Back Bay ladies on March 3 and 4, netted the Industrial School for Crippled and Deformed Children $7,000.

Senate Kills Bill.—The senate has voted not to pass a bill which had the approval of the house but the opposition of the public health committee, to further regulate the examination of bodies before embalming and burial.

Pauper Institutions Need Money.—The trustees of pauper institutions in Boston, in support of their pleas for an appropriation of $187,000 for this year, state that they have now under their care 830 sick or destitute people, 80 per cent. of cases admitted during the last year having been sent directly to the hospital, which must soon be enlarged.

Embezzlement Cripples Consumptive Home.—St. Luke's Home for Consumptives, Roxbury, is seriously embarrassed by reason of the embezzlement of at least $34,000 of its funds, and probably many thousands more, by its treasurer, Wallace H. Ham, who also took almost $200,000 from the American Surety Company. This home has done a good work in caring for this class of patients for which the city of Boston officially does so little.

Against Restriction of Animal Experimentation.—Vigorous efforts to introduce in the legislature a bill to further restrict animal experimentation in Massachusetts were combated before the committee on probate and chancery by the able arguments of Prof. H. C. Ernst, who represented officially Harvard Medical School, Tufts Medical School, Boston University Medical School, the Massachusetts Institute of Technology, Clark University, and various other educational institutions in the state and also local boards of health. He presented a protest signed by thirty-one of these boards in cities and towns.

NEW YORK.

Smallpox has again appeared at North Tonawanda and Niagara Falls.

Three More Ratifications.—In addition to the fourteen county societies mentioned last week, the Montgomery, Orange and Rockland county medical societies have ratified the plan of union of the New York State Medical Society and the association.

Personal.—Dr. Joseph A. Lanahan, Albany, has been made a member of the staff of the State Hospital for Insane Criminals, Dannemora.——Dr. Warren L. Ayer has been made health officer of Owego.——Dr. Martin S. Reed has been reappointed health officer of Coeymans.

For Study of Defectives.—A bill to establish a laboratory for the study of the criminal pauper and defective classes is proposed to be introduced in the legislature. Such a bureau would have for its purpose the gathering of data of sociologic, pathologic or abnormal conditions.

Crippled Children's Hospital Report.—The New York State Hospital for the Care of Crippled and Deformed Children, Tarrytown, recently has sent out its report for the year ended September, 1903. Dr. Newton M. Shaffer of New York is surgeon-in-chief of the hospital, and Drs. Roswell Park and Charles G. Stockton of Buffalo are on the consulting staff. The board of managers express the wish that the names and addresses of poor children who are crippled and deformed be sent to the surgeon-in-chief at Tarrytown.

Buffalo.

Personal.—Dr. Harvey R. Gaylord has returned from Europe. ——Dr. Albert H. Briggs was appointed grand state medical examiner of the A. O. U. W.——Dr. Chauncey P. Smith recently fractured his left leg by slipping on an icy sidewalk.

Report on Cancer Research.—The fourth annual report of the work of the cancer laboratory of the New York State Board of Health conducted at the Gratwick Research Laboratory University of Buffalo for a period beginning in 1902 and ending in 1903, was transmitted to the legislature. It contains the report of the director, Dr. Roswell Park, and several scientific papers, all pertaining to investigations bearing on the question of cancer. Many of the papers are illustrated with microphotographs.

Oppose Optometry Bill.—The Buffalo Academy of Medicine has been informed that a number of physicians have signed postal cards circulated by opticians favoring the passage of their bill now before the legislature as Senate Bill No. 378. A closer examination of this bill shows that it is a permission to practice medicine. It has been condemned by resolutions of the New York State Medical Society, by the Buffalo Academy of Medicine, and by the medical press. The Buffalo Academy of Medicine has recommended that the medical profession write personal letters to their representatives at Albany in opposition to this bill.

New York City.

Personal.—Dr Joseph Brown Cooke has been appointed adjunct professor of obstetrics in the New York Polyclinic.

German Hospital Bequest.—By the will of John Schultheis, who died February 4, $1,000 is bequeathed to the German Hospital, Williamsburg.

Pneumonia Season Mortality.—During the current pneumonia season, from November 1 to March 5, New York reported 26,195 deaths, 5,506 being due to pneumonia, and 2,908 to tuberculosis.

Club Rooms and Library Opened.—The Eastern Medical Society of the City of New York opened its library and club rooms March 1. Addresses were delivered by Drs. Abraham Jacobi, Kenneth W. Millican and Joseph D. Bryant, and a concert and supper followed.

Pneumonia and Consumption.—For the week ended March 5, 1,800 deaths were reported, 460 of which, or 25.5 per cent., were due to pneumonia, and 188, or 10.4 per cent., to consumption. Bellevue Hospital has about 300 cases of pneumonia, and other hospitals have a proportionate number. At Bellevue the influenza bacillus was found in about 70 per cent. of the respiratory cases.

May Remove Consumptives' Home.—On the complaint of neighboring property holders that the Consumptives' Home, Brooklyn, is a menace to their health, Assemblyman Remsen has introduced a bill authorizing the commissioner of health to investigate the conditions at the institution, and, if he sees fit, to provide for the removal of the inmates to some other place provided by the trustees.

Regret Dr. Weir's Retirement.—On the retirement of Dr. Robert F. Weir from the chair of surgery, which he had held for ten years, the faculty of the College of Physicians and Surgeons unanimously passed resolutions setting forth the eminent services rendered to his alma mater by Dr. Weir, during the thirty-six years of his official connection with the institution, and eulogizing him as teacher, surgeon, and man.

Dinner to Dr. Roosa.—On March 1 about 400 physicians, representing the cis-Mississippi division of the United States, met at a dinner at Delmonico's in honor of Dr. D. B. St. John Roosa, and to commemorate the twenty-one years since the inauguration of postgraduate medical instruction in this country. Dr. William Osler, Baltimore, presided, and at the speaker's table were seated Drs. Roosa, William T. Bull, New York; Clarence J. Blake, Boston; William M. Polk, New York; William J. Mayo, Rochester, Minn.; John H. Musser, Philadelphia; Maurice H. Richardson, Boston; Edward G. Janeway, New York; William W. Keen, Philadelphia; Robert F. Weir, New York; William H. Welch, Baltimore, and John A. Wyeth, New York. A massive silver loving-cup was presented to Dr. Roosa, Rev. Dr. Vincent making the presentation address. Dr. Osler reviewed medical progress for the last twenty-five years, and suggested the following steps in advance which ought to be taken: Third and fourth year students should have the right to pursue their studies in hospitals; a better equipment and more schools for scientific investigation should be provided; interstate reciprocity of medical licensure is essential, and consolidation and unification in medical teaching is the fourth improvement needed. He prophesied that in ten years there would be only one medical school in New York. Dr. Clarence J. Blake, Boston, introduced as a "special specialist," spoke on the need of postgraduate instruction for the specialist, and suggested that the present practice of specialties contained an element of danger to the public by reason of the lack of a proper standard of instruction. Dr. William W. Keen, Philadelphia, in his address on "The Necessity for Increased Endowment for Medical Institutions," referred to the increased commercial value to the people at large of the work of the physician and cited as examples modern sanitation in Cuba, with its practical abolition of yellow fever; the diminution of susceptibility to bubonic plague, smallpox and malaria. He referred to the work of the profession in the direction of preventive medicine, and gloried in the fact that the medical profession was the only one on the earth which was bending its energies toward self-destruction. He called attention to the fact that the endowment for theological schools amounts to $2,250 for each student, while the endowment for medical schools amounts to only $83 per student. Dr. William M. Polk, New York, called medical teaching as it exists in most institutions an absolute farce, because in many of its branches it is conducted solely for the benefit of the teacher. The public should be made to appreciate that it is absolutely necessary to use the human body to obtain the very essence of that knowledge necessary to make medicine a perfect work. Civic pride in medical institutions did not exist, because the institutions had not yet reached the requisite condition of efficiency. Dr. Roosa, in conclusion, said:

> To men of great affairs in trade, commerce and politics the medical profession sometimes may seem inferior. We may perhaps be thought mere hewers of wood and drawers of water to the priests and Levites who minister at the great temples of the world, but not so. We can very properly compare ourselves to the engineers and stokers of a great man-of-war, or better, a great transport of passengers and freight.
>
> We are not seen, we are grimy and often worried with the struggle, but it is we who keep down the epidemics, who prevent cholera from coming to our shores, who stamp out yellow fever, and who are planning that that day shall come foretold by the prophet 2,000 years ago, "when no man shall say that I am sick," but, like the one-hoss shay, shall finally, in the fruition of his days, pass into the other life by a general breaking up, no one part failing before the other, and so cease to exist.

OHIO.

Personal.—Dr. Samuel S. Wilson, Xenia, president of the Greene County Medical Association, has gone to Cuba for a month.——Dr. S. D. Clayton, Cincinnati, has been appointed to the Board of Pension Examiners to fill the vacancy caused by the death of the late Dr. Spencer. Dr. P. S. Connor, Jr., Cincinnati, has been appointed district physician in place of Dr. Harry Thomas, resigned.

Typhoid in Cleveland.—On March 1 51 cases of typhoid fever were reported, the largest in any one day in the history of the present epidemic. During February 465 new cases were reported, with 45 deaths. The epidemic is believed to be due to polluted lake water, the new tunnel not being as successful in supplying pure water as was expected. The health officer favors a filtration plant, but is opposed by the city officials and council.

Medical Semi-Centenary.—Dr. Benjamin R. McClellan, Xenia, entertained the Greene County Medical Association and a number of invited guests from other cities at a dinner given in honor of the fiftieth medical anniversary of his father, Dr. Harvey B. McClellan. Dr. Clark M. Galloway, Xenia, officiated as toastmaster. Drs. Starling Loving, Columbus; Isaac Kay, Springfield; Hudson B. Stevens, Columbus; John C. Reeve, Dayton, and Thad A. Reamy, Cincinnati, responded to toasts, and the guest of honor was the last speaker.

Jewish Hospital Improvements.—Plans are being drawn for a number of improvements to be added to the Jewish Hospital, Cincinnati. These consist of a nurses' home, a large power plant, which will supply the energy for heat and light to the hospital and its supplemental buildings, as well as for the Home of the Jewish Aged and Infirm situated near the hospital. The most important of the new buildings will be a children's hospital of large size. The cottage plan of building will be the one used. This work will all be done by private subscription, and already large sums have been donated by the wealthy residents of the city.

PENNSYLVANIA.

Philadelphia.

Quarantine Lifted.—The quarantine on the medical department of the Episcopal Hospital established several weeks ago has been lifted, and general work in this department is again established.

Small Fire in Hospital.—On March 5 a fire occurred in the drying room of the laundry in the Kensington Hospital for Women. The flames, however, were early controlled, and little damage was done.

Wholesale Vaccination.—Dr. Thomas J. Beattie, assistant medical inspector, accompanied by a corps of 42 vaccination physicians, recently raided the foreign quarter of the city and vaccinated over 600 persons, mostly children of school age.

Will Not Sue for Water Pollution.—There is no foundation for the report that proceedings were instituted in behalf of Philadelphia against Norristown and other municipalities which are believed to pollute the Schuylkill River by emptying drainage into it. Dr. Alexander C. Abbott, chief of the bureau of health, has advised that no steps be taken in this direction.

Baby-farmers Arrested.—During the past week three more proprietors of the so-called "baby farms" were arrested in this city. During the past year 60 infants have been found on doorsteps, or dead in vacant lots. The authorities believe that many of these foundlings come from these dens and not from individual homes, as was formerly supposed. It is also believed that many of these infants are used for blackmailing purposes, while others are disposed of by different means.

Reception to Ridlon.—The Epsilon Chapter of the Alpha Kappa Kappa of Jefferson Medical College, gave a reception in honor of Dr. John Ridlon, Chicago, at their chapter house, February 29. The members of the faculty of Jefferson Medical College and men prominent in the medical profession of the city were present. On March 1 Dr. Ridlon held a clinic in the Jefferson Medical College Hospital before a large audience. He performed an operation for congenital dislocation of the hip by the Lorenz method.

Against Tuberculosis.—Dr. Lawrence Flick, head of the Phipps Institute and the White Haven Sanitarium for Consumptives, addressed the Civic Club at the College of Physicians. He urged the necessity for the registration of tuberculosis, and the necessity for disinfection for both the incipient and advanced stages, and said that Philadelphia is the only city of its size in the world which has not entered as a municipality into the efforts of stamping out the disease. He said that Philadelphia was the chosen rostrum from which the world was taught how to combat tuberculosis, but yet the municipal government had never appropriated one penny toward the advancement of the work. The Civic Club has promised to advance the cause of the crusade against consumption by legislation and by advancement of public spirit in its favor.

Personal.—Dr. Charles B. Penrose was unanimously elected a member of the governing body of the Academy of Natural Sciences, to fill the vacancy caused by the resignation of Charles Cramp.——Dr. Max H. Bochroch, chief demonstrator of neurology in the Jefferson Medical College, has been elected chief in the neurological department in St. Joseph's Hospital.——Dr. Edward E. Montgomery held a public clinic at the Philadelphia Hospital, February 27, before a large audience. He performed the Doyen operation of hysterectomy for multiple fibroid tumors of the uterus. This was Professor Montgomery's first appearance before the class since he resigned ten years ago. It was stated in his introduction that he performed the first successful public ovariotomy in Philadelphia in 1879, and the first ovariotomy performed in the Philadelphia Hospital.

Health Report.—Typhoid fever still prevails throughout the city to an alarming extent; 195 new cases have been reported during the week ended March 5. This is the largest number recorded for several years. Every ward of the city, except three, is infected. The source of infection is said to be due to the disturbance of the water supply by the recent freshets. The health authorities have issued bulletins advising that all water be boiled. The figures reported show an increase of 47 over those of last week. The deaths from the disease were 19. The reports of contagious diseases for the week are: Diphtheria, 62 cases, 10 deaths; scarlet fever, 89 cases, 8 deaths; smallpox, 33 cases, 6 deaths; typhoid fever, 195 cases, 19 deaths. The total number of deaths from all causes was 628, a decrease of 65 from those of last week, and an increase of 14 over the corresponding period of last year. Pneumonia heads the list with 116 deaths; consumption caused 64 deaths; heart disease, 50, and Bright's disease, 40.

GENERAL.

Anniversary of First Demonstration of Cystoscope.—The twenty-fifth anniversary of the first demonstration of the cystoscope by Prof. Max Nitze, Berlin, occurred March 9 and was celebrated appropriately by Dr. Nitze's confrères in Berlin. An address was presented, signed by appreciative practitioners in the line of genito-urinary diseases. A cablegram was sent from New York, congratulatory to Professor Nitze, and because of the lateness of notification, the names of those who wish to sign the congratulatory address are to be forwarded to be appended *post festum*. Dr. Ferd. A. Valentine, 31 West 61st Street, New York City, has accepted the invitation of the Berlin committee to forward the names of American pupils and friends which shall be sent to him for that purpose.

CANADA.

Outbreak of Smallpox.—Twenty-three cases of smallpox are reported in Kingsey township, near Sherbrooke, Quebec.

New Hospital Wing.—A new wing has been added to the Charlottetown, P. E. I., hospital, fully equipped for surgical operations, and also for the care of patients with infectious diseases.

Demonstrator of Anatomy at Queen's University.—A special demonstrator in anatomy will be appointed to devote his whole time to the work. He will have the standing of lecturer and will in time be given a professorship.

Jeffrey Hale Hospital, Quebec.—The annual report for the year 1903 shows in the private and public wards 147 surgical, 221 medical, and 135 ophthalmic cases treated; total 503. In the outdoor departments 1,800 patients were treated.

Personal.—Dr. A. D. Blackader, Montreal, has returned from Bermuda, where he spent two months. He is much improved in health.——Dr. George N. Murphy, St. John's, Newfoundland, and his brother, Dr. Charles R. Murphy, Windsor, N. S., have gone to New York for postgraduate work.

Results with Marmorek's Serum in Montreal.—Some time ago Dr. Marmorek's serum was given a trial in the Notre Dame Hospital, Montreal, on one surgical case and on one of tuberculosis of the lungs. The results in the first case were nil, there being noticed neither good nor bad effects. In the lung case the results were bad; the patient received in all nine injections. The sputa were weighed every day during the injections and showed a daily increase up to two ounces on the ninth day. At the beginning of the treatment the patient weighed 118 pounds. After the ninth injection there was a loss of three pounds, and the cough increased and was more harassing. The treatment was then discontinued at the patient's own request.

Dissecting Material in Ontario.—A bill came before the Ontario legislature last week of more than ordinary moment to the medical student body. It was designed to prevent the handing over of the bodies of people who die in houses of refuge to the medical colleges for dissecting purposes. As the law now stands bodies must be claimed by friends within twenty-four hours or else they go to the dissecting table. The promoter of the bill stated that the lives of the inmates were rendered anxious over the disposal of their bodies in case of death, and he wanted the matter left in the hands of the warden of each county and the manager of each institution. The medical men in the legislature opposed the bill on the ground that it would cut off from 40 to 50 per cent. of the dissecting material, and that if the bill became a law, it would be sure to be productive of the former practice of stealing bodies. At present the bill is before a committee.

FOREIGN.

Money to Oxford.—A studentship in pathology in Oxford University, England, is to be established with $6,000 given by Mr. Philip H. Walker.

New Buildings at Cambridge.—A number of new buildings were opened for use at Cambridge University, England, March 1, including the new medical school building.

Official Inspection of the Paris Hospitals.—Nine inspectors have been appointed who are to be delegated to spend ten days each in the Paris hospitals in turn to inspect the working of the establishment and suggest measures for retrenchment of expenses, as well as other points to which attention should be directed.

Sanitary Reforms at Madrid.—The Spanish government has appropriated nearly half a million dollars for reforms at Madrid. The committee entrusted with the task of deciding the measures to be adopted reports in favor of establishing a disinfecting plant, repairing the pavements and improving the water-bringing plant and "East park," and devoting half the sum to the construction of three public school buildings.

Exhibition at International Congress of Ophthalmology.—Prof. A. Siegrist of Berne, Switzerland, has charge of the preparations for the appropriate exhibition of all scientific apparatus, instruments, and the various appliances for instruction, which will be sent to the Tenth International Congress of Ophthalmology, to convene at Lucerne, Sept. 18, 1904. He, therefore, requests all colleagues, as well as all scientific, optical, and mechanical firms who wish to exhibit any objects at the congress to apply to him before July 1, 1904, giving an exact statement of the object to be exhibited, of the space demanded, and of the kind and strength of electric force which may be required. Articles announced later can be accepted only so far as the space at disposal will still allow at that late date.

Health in Word and Picture.—This is the title of a new German ten-cent monthly magazine recently founded at Berlin which proposes to supply the reading public with popularly written articles on scientific medicine. The first number contains articles by Kassowitz of Vienna, on children's diseases, by Pelman of Berne, the psychiatrist, and by Casper of Berlin, the urologist. The title in German is *Gesundheit in Wort und Bild.* The periodical is founded by Drs. Weissbein and Lipliawsky, who already issue the *Russiche med. Rundschau* at Berlin and *Therapia* at St. Petersburg. They have also founded at Berlin a "consulting institute" for Russians. Persons arriving at Berlin wishing to consult physicians but unacquainted with any language but Russian, apply to this institute for information and advice. They are thus saved from falling into the hands of charlatans.

Student Riots in Paris.—The medical students of Paris are making an energetic protest against the proposed abolition of the age limit for university professors, and also against the changing about of professors from one chair to another. They have refused to allow a single professor to lecture since the senate adopted a resolution in favor of abolishing the age limit. After first informing the professor that the manifestation is not against him personally, they proceed to make such a noise, hooting and yelling, that he is unable to proceed. These scenes of violence have been repeated in every amphitheater, and have been followed by several acts of vandalism. Their motto is "Room for the young"; and they proclaim that they do not want driveling old men for their instructors. In regard to the frequent changing of chairs they mention as an instance that Chantemesse, who has been studying serums for ten years, has just been abruptly transferred to the chair of anatomy. This custom of "permutations" is peculiar to France, we understand, and the students consider it a disgrace to science, as no man can be equally eminent in and devoted to more than one specialty at a time. They do not want a teacher whose heart is not in his work.

Homage to Professor Bouchard of Paris.—Nearly the entire number of the *Presse Médicale* of February 24 is devoted to the ceremonies connected with the presentation to Professor Bouchard of a portrait medal. He is regarded as a typical example of all that there is of beautiful, noble, useful and beneficent in the science and art of medicine at the opening of the twentieth century. The manifestation of homage to him thus corresponds, the editor remarks, to one of the most beautiful periods in the history of medicine, and the addresses made are full of interest to all practitioners of medicine at home and abroad. Bouchard has been the representative of France at numerous foreign congresses and delegates from the various countries had assembled with his friends and those who had felt his influence in their professional career. His tact and prudence, his luminous and sound opinion on medical matters and his farsightedness and kindliness were extolled. In the closing words of his acknowledgment of all this homage, he summarized his "medical faith" in the six maxims: "Seek truth. Discover causes. Learn how they disturb life, and how order is re-established. By science and persuasion preserve men. By science, gentleness and firmness combat death and reduce suffering. Guide, encourage and console in a brotherly and tolerant spirit. C'est la Médecine."

Correspondence.

Duration of Life After Fatal Injuries.

Madison, Wis., March 5, 1904.

To the Editor:—In The Journal, March 5, a letter by Dr. H. D'Arcy Power of San Francisco brings to mind the following: At the time of our capitol disaster I was early on the scene; one of the first of the injured to be brought out was the foreman. He was immediately removed to a building nearby. On examination, I found his injury a fatal one, the entire calvarium being fractured and cleanly driven through the brain to the base of the skull. Respiration was normal, the respiratory center being uninjured. On endeavoring to raise the fragments respiration ceased, to be immediately resumed when left undisturbed. He lived three hours after receiving his injury.

J. A. Mack.

Eyestrain as a Cause of Headache and Other Nervous Symptoms—A Question of Precedence.

New York City, March 3, 1904.

To the Editor:—In your issues of Jan. 16 and Jan. 23, 1904, Dr. George M. Gould publishes an interesting article concerning the dependence of "Migraine" on eyestrain. In this article he goes extensively into the history of the literature relating to this distressing and extremely common malady.

In this connection he makes the most remarkable statement regarding a contribution of a French oculist to this field. He says (italics are my own):

> In 1888 Dr. G. Martin (*Ann. d'Oc.*), a French oculist, published an article which *some time will be recognized as truly epoch-making.* But two writers, as far as I have noticed, have even mentioned Martin's magnificent and daring attempt to bring the medical world to its senses.

A compiler should certainly have shown more care than Dr. Gould appears to have shown in reviewing medical literature, before he ignores the work of his own countrymen and gives credit for "epoch-making" to a French author who simply confirmed observations that had been made many times before, and who supported views that had been fought for for years in America by myself and others.

If Dr. Gould had simply taken the trouble to look up medical literature on this subject prior to 1888, he would have found in the *New York Medical Journal* of 1886 an article by myself entitled "The Eye as a Factor in the Causation of Some Nervous Symptoms," and in the *Medical Bulletin* of September, 1887, an article by myself entitled "Eyestrain in Its Relation to Functional Nervous Diseases"; and in the *New York Medical Journal* of April, 1887, an article by myself entitled "Eyestrain in Its Relation to Neurology." Had he looked over the text-books on nervous diseases, he would have found that my large work entitled "Lectures on Nervous Diseases" (F. A. Davis, Phila., 1888), antedated Dr. Martin's article. This work contained the first résumé of eyestrain ever published; as a factor in causing not only migraine, but other equally common nervous symptoms, such as sleeplessness, neuralgias, chorea, epilepsy and insanity. At least one hundred pages in total were devoted by me to the eyestrain directly or indirectly.

From 1880 to 1883 I made my early combats for the eye treatment of headache before the New York Academy of Medicine and the Neurological Society of New York. During the same period of time (which antedates Dr. Martin's article by some years), I also made this subject an important part of the courses of lectures delivered by me each year before the students of the Postgraduate Medical School and Hospital of New York and also before the classes of the University of Vermont. I based these lectures and discussions on my own remarkable restoration to health from a condition of hopeless physical collapse through the detection and correction of latent hypermetropia. This had escaped recognition by means of the ophthalmoscope in the hands of three of the leading ophthalmologists of that period. As careful refractive work was done by me for headaches as early as 1880 as is done to-day.

Again, Dr. Gould can not be unaware of the fact that the prize offered by the Royal Society of Belgium for the best original essay on the treatment of epilepsy was awarded in 1886 to Dr. George T. Stevens of New York for a contribution by him, in which eye treatment alone was employed in that disease, and in which the relationship of eyestrain to headache was mentioned, if my own memory serves me correctly, on several pages. The essay was published in English by D. Appleton & Co. of New York in 1887.

In closing, I would say that I deem it a proper time to raise my voice in earnest protest against the method (too commonly in vogue to-day) of giving undue credit to foreign authors for pioneer work in new fields to the exclusion of Americans, who have sounded the first keynote in many of the great discoveries in medicine. It is not only unpatriotic, but it is unjust to forget or to ignore the early struggles that were made to establish on its present footing the view that "eyestrain is one of the most prolific sources of functional nervous derangements." A. L. RANNEY, M.D.

345 Madison Avenue.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

ALKALINE TREATMENT OF HYPERACIDITY.

A TOLEDO, OHIO, CORRESPONDENT, whose language indicates that he is not a physician, writes with enthusiasm of a physiologic discovery he has made of a self-curative process in his own nature. His method is "simply to excite and swallow a copious flow of saliva, by mechanical compression and self-suction of lips and gums, whenever 'rising of the bile' causes sudden nausea and disposition to vomit; that is, in all cases of 'biliousness' as commonly designated." He is over 60 years of age, and for more than thirty years has been "troubled often with sudden sick spells of rising bile—biliousness—that would last for hours or even days, and would necessitate treatment with alteratives, purges, emetics, etc." "Scarcely a month would pass without one or more of such attacks, until about eighteen or twenty months ago, when this discovery was first made and utilized." Since that time, he says, every attack is dispelled as suddenly as it appears, there are no ill effects and no [other] medicine is required, "no matter how extreme the sudden sickness or how apparently overwhelming the disposition to vomit." Our correspondent's trouble may be hyperacidity of the stomach; he says the "spells come on some time after eating, on an empty stomach, often at night in bed before going to sleep, and sometimes awakening me from sleep." The alkaline treatment of hyperacidity is certainly "physiologic" and "natural," for the alkaline saliva neutralizes the acid secretions of the stomach, but the method is not new. Physicians make use of a dilute solution of bicarbonate of soda—a most efficacious remedy for the symptoms described—but some practitioners suggest the chewing of gum, which increases the flow of the alkaline saliva into the stomach.

THE CHRISTIAN HOSPITAL AGAIN.

HOLLINGER, ALA., March 3, 1904.

To the Editor:—Please inform me about the Christian Hospital membership. Is it any good, or is it only a fake to make money? They have sent me a skeleton certificate with a formidable array of signatures. I would like to have one if it is any good. Eight, ten and twelve dollars are the fees quoted. J. N., M.D.

ANNISTON, ALA., March 4, 1904.

To the Editor:—I enclose some circulars recently received. There may be some gullible enough to be taken in by this kind of an institution. ALLEN A. GREEN.

ANSWER.—We respectfully refer the above and others to THE JOURNAL, May 23, 1903, p. 1443, June 6, 1903, pp. 1587 and 1591, where this scheme was exposed. Evidently these people are "hard at it" again, for every mail is bringing us communications similar to the above, and usually we are favored with the circulars, including those which show the beautiful diplomas that are supplied so cheaply. We note that Dr. John B. Murphy's name is prominent on the diploma, although another name is substituted with a rubber stamp.

MADSTONES.

SNYDER, OKLA., March 1, 1904.

To the Editor:—Will you give some information of the madstone, which so many of the laity believe to be a cure-all for hydrophobia? What is it? M. A. J.

ANSWER.—Madstones are simply porous stones without any special powers excepting those of absorption. Perhaps in some cases they may be like the snake stones of India, as shown by Faraday, and still more recently by Watkins-Pitchford (*Br. Med. Jour.*, Feb. 20), occasionally composed of calcined bone and thus may have a little of the absorbent action of animal charcoal. As the great majority of the persons bitten by so-called mad dogs are not likely to have hydrophobia, they can get up a certain amount of reputation for madstones very easily and the psychic or suggestive action may in some cases be of value in nervous people.

LITERATURE ON HOUSE SEWERAGE.

ALLENTOWN, PA., Feb. 29, 1904.

To the Editor:—I am associated with some friends who are about to ask our city for a franchise to build a house-sewerage system here. Where can I obtain the desired information how to educate the masses through the public press, i. e., what books, writings, etc., are to be had? I. F. H.

ANSWER.—Two of the best books on sewage disposal are "Sewage and Bacterial Purification of Sewage," by Samuel Rideal, John Wiley and Sons, New York, $3 50; and "Sewage Disposal Works," by Santo Crimp, London, C. Griffin & Co., $6.00. Other useful works are "Sewerage," by A. Prescott Folwell, John Wiley and Sons, $3.00, and "Sewage Disposal," by Wynkoop Kiersted, John Wiley and Sons, $1.25. Most of these books have gone through several editions and the latest issued should be obtained.

THE N RAYS A NEW MEANS OF DETERMINING DEATH.

VERA CRUZ, MEXICO, March 2, 1904.

To the Editor:—Do only living bodies emit N rays? In this case shall we not have in that property a new and decisive proof to ascertain the death? CARLOS MANUEL GARCIA.

ANSWER.—Some of the investigators have so asserted. It may be, however, that in the state of "trance," with all functions almost entirely suspended, the production of N rays will also be suspended and the test fail. Those who wish to read about N rays are referred to THE JOURNAL, Jan. 23, 1904, p. 275, abstract 59, and Feb. 6, 1904, p. 404, abstract 14, where articles are referred to. See also foreign abstract No. 34 next week.

PRACTICE IN INDIAN TERRITORY.

CARROLLTON, KY., March 1, 1904.

To the Editor:—Will you let me know through THE JOURNAL the requirements of the laws that govern the practice of medicine in the nations of the Indian Territory? M.D.

ANSWER.—In the Creek nation an authentic diploma or examination is required; in the Cherokee and the Choctaw nations an examination.

THIOSINAMIN FOR REMOVING SCAR TISSUE.

DR. L. F. GULDNER, Davenport, Iowa, asks how much value there is in thiosinamin applied hypodermatically and locally to remove scar tissue, such as the induration remaining after a boil.

ANGLO-AMERICAN MEDICAL ASSOCIATION, BERLIN.

L. A., Atlanta, Ga., writes for the address of the above, and is referred to THE JOURNAL, Jan. 30, p. 320, and Feb. 20, 1904, p. 545.

Marriages.

WILLIAM HERBERT GRANT, M.D., to Miss Edith A. Borchardt, both of Boston, February 22.

JOSEPH H. BOGLE, M.D., Fyffe, Ala., to Miss Eula Whorton, of Centre, Ala., February 25.

GLENN HENLEY, M.D., to Miss Margaret May James, both of Fairmount, Ind., February 26.

DAN HAZEN MOULTON, M.D., to Miss Flora Meister, both of Sacramento, Cal., February 24.

GEORGE S. MURRAY, JR., M.D., to Miss Jennie E. Haight, both of Crescent, N. Y., February 24.

GEORGE A. PAZDRAL, M.D., to Miss Julia Sladek, both of Fayetteville, Texas, February 16.

FRANK A. BATTON, M.D., Clarksville, Ohio, to Miss Otta Smith of Milford, Ohio, February 23.

JAMES WILSON CROFT, M.D., Corning, Ohio, to Miss Mary C. Glick of Columbus, Ohio, February 23.

ELWOOD ROBISON, M.D., Rossville, Ind., to Miss Zella Van Why of Michigantown, Ind., February 17.

FRANCIS SEALS BELCHER, M.D., Mansfield, Ga., to Miss Rena Maude Starr of Starrsville, Ga., February 24.

Deaths.

Ogden Curtis Ludlow, M.D. New York University, 1883, a member of the American Medical Association, and section reporter for several years; a member of the New York State Medical Association; secretary of the New York County Medical Association; a member of the Society of Alumni of St. Luke's Hospital, died March 2 at his home in New York City, from typhoid fever contracted while in attendance on the meeting of the New York State Medical Society in Albany, last January. The immediate cause of death was hemorrhage from a perforating ulcer. Dr. Ludlow was the New York correspondent of The Journal, and had filled this position acceptably for a long time. He possessed to an unusual degree the faculty of extracting the pith of articles and discussions.

Jefferson Cushing Gallison, M.D. Boston University, 1875, College of Physicians and Surgeons, Boston, 1888; Tufts College, Boston, 1894; Harvard University Medical School, Boston, 1895; a member of the legislature; demonstrator of anatomy at the College of Physicians and Surgeons from 1889 to 1892; lecturer on surgical pathology at Tufts Medical College, 1893; member of the Massachusetts Medical Society and of the Thurber Medical Society, died from heart disease at his home in Franklin, Mass., February 22, aged 62.

Dallis M. Wick, M.D. Chicago Medical College, 1874, a member of the American Medical Association; second vice-president of the Iowa State Medical Society; member of the Iowa State Association of Railway Surgeons, and the Austin Flint and Blackhawk county medical societies, one of the prominent physicians of northwestern Iowa, died at his home in Cedar Falls, March 1, after an illness of several months, aged 63.

William Rankin, Jr., M.D. College of Physicians and Surgeons, New York, 1871, for many years secretary of the Newark Charitable Eye and Ear Infirmary, a member of the American [illegible] Association, the American Otological Association, [illegible] Society of New Jersey, and the Essex District Medical Society, died at his home in Newark, N. J., February 25, after an illness of one week, aged 53.

Guy B. Case, M.D. University of Wooster, Cleveland, 1873, a member of the American Medical Association; professor of dermatology and venereal diseases at the Cleveland College of Physicians and Surgeons; one of the prominent physicians of Cleveland, died at his rooms in that city, February 26, from pneumonia, aged 52.

Arthur Collis Gibson, M.D. Medical School of Maine, at Bowdoin College, Brunswick, 1885, member of the Maine Medical Association, and of the Penobscot County Medical Association, died from septicemia, due to an ulcerated tooth, February 21, after an illness of eight days, at his home in Bangor, Maine, aged 43.

David L. Wallace, M.D. Bellevue Hospital Medical College, New York, 1875, a member of the American Medical Association; for many years secretary of the Newark Board of Health, died at his home in Newark, N. J., February 29, from eumonia, after an illness of four days, aged 48.

William W. Highlands, M.D. Medical College of Ohio, Cinnnati, 1850, the oldest physician in Hamilton County, Ohio, died, February 29, at his home in Newtown, aged 81. He served as surgeon in the Civil War, and in 1883 was a member of the Ohio State Legislature.

Thomas S. Galbraith, M.D. Medical College of Ohio, Cincinnati, 1866, formerly superintendent of the Central Indiana Hospital for the Insane, Indianapolis, and of the Oklahoma Insane Hospital, Norman, died at his home in Seymour, Ind., February 23.

Howard C. Russell, M.D. University of Pennsylvania, Philadelphia, assistant surgeon U. S. P. H. and M. H. Service, stationed at New York, died at the Marine Hospital, Stapleton, Staten Island, from pneumonia, after a short illness, March 2.

John H. Bledsoe, M.D. Memphis (Tenn.) Medical College, 1896, secretary of the Chambers County Medical Society, and a member of the Medical Association of the State of Alabama, died at his home in Lafayette, Ala., January 4, aged 29.

Elbridge G. Hard, M.D. Cleveland Medical College, 1850, surgeon to the First Ohio Light Artillery in the Civil War, died at his home in Medina, Ohio, February 28, from malignant disease of the neck, after a long illness, aged 77.

William F. Buchanan, M.D. University of Pennsylvania, Philadelphia, 1862, assistant medical director in the Civil War, and afterward in the regular establishment until 1867, died at his home in Philadelphia, February 16.

James E. Magee, M.D. Western Pennsylvania Medical College, Pittsburg, 1892, of Seneca, Pa., died recently. The Oil City Medical Club furnished pall-bearers for the funeral and drafted resolutions of regret.

William M. Burgess, M.D. Louisville Medical College, 1882, of El Paso, Texas, was, it is feared, one of the unidentified victims of the Iroquois Theater fire in Chicago, Dec. 30, 1903.

Jacob Allen Hall, M.D. Physio-Medical Institute, Cincinnati, 1870, of Palatka, Fla., died in Indianapolis, March 1, aged 81.

Robert J. Wilding, M.D. Apothecaries' Hall, London, England, 1856, secretary of the Franklin County Medical Society, died suddenly at his home in Malone, N. Y., February 24, from heart disease, aged 67.

Enoch Lewis, M.D. Cleveland Medical College, 1867, died at his home in Oskaloosa, Iowa, March 2, from pneumonia, after a short illness, aged 67. He had been an invalid from paralysis for seven years.

Tobias J. Butler, M.D. Faculty of Medicine of Queen's University and Royal College of Physicians and Surgeons, Kingston, Ont., 1895, of Chicago, died in January, 1903, from tuberculosis, aged 48.

W. S. Ruby, M.D. Homeopathic Medical College of Missouri, St. Louis, 1878, while despondent from protracted ill health, shot and killed himself at his home in Riverside, Cal., February 22.

Coit H. Kendall, M.D. Bennett College of Eclectic Medicine and Surgery, Chicago, 1878, died at his home in Barrington, Ill., February 21, after an illness of two weeks, from pneumonia, aged 45.

Theophilus Smith, M.D. Jefferson Medical College, Philadelphia, postmaster of Wausau, Wis., from 1868 to 1876, died at his home in Wausau, February 27, after an illness of a week, aged 87.

Frank E. Baker, M.D. College of Physicians and Surgeons, New York, 1882, died at his home in Newark, N. J., March 1, as the result of injuries sustained in a fall, February 8, aged 47.

Theodore Young Kinne, M.D. Albany (N. Y.) Medical College, 1862, assistant surgeon of volunteers in the Civil War, died at his home in Paterson, N. J., March 4, from heart disease, aged 65.

Frank M. Severson, M.D. College of Physicians and Surgeons, New York, 1889, died at his home in Seneca Falls, N. Y., March 1, from pneumonia, after an illness of one week, aged 40.

Peter Arnold, M.D. Washington University, St. Louis, 1895, a member of the American Medical Association, died at his home in Wellsville, Mo., February 25, aged 35.

Thomas B. Cosford, M.D. Trinity Medical College, Toronto, 1876, of Lockport, N. Y., died in Redlands, Cal., from consumption, February 26, after a long illness, aged 57.

Hermann Moter, M.D. University of Giessen, Germany, 1847, who retired from active practice in 1891, died at his home in Reading, Pa., February 22, aged 83.

Charles B. Pillsbury, M.D. Hahnemann Medical College, Chicago, 1879, died at his home in Duluth, Minn., March 2, from an abscess of the throat, aged 52.

Abraham Hicks Price, M.D. University of Maryland, Baltimore, 1861, died at his home near Towson, Md., March 1, after an illness of ten years, aged 64.

Orton Woodruff Peterson, M.D. Hahnemann Medical College, Philadelphia, 1859, died at his home in Waterloo, N. Y., February 27, from heart disease.

David B. Hale, M.D. Eclectic Medical Institute, Cincinnati, 1869, died at his home in West Liberty, Ohio, February 26, from epithelioma of the face.

William C. Mills, M.D. McGill University, Montreal, 1893, died suddenly at his home in Chateaugay, N. Y., February 23, from heart disease, aged 38.

J. A. Huntsman, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1875, was found dead at his home in Austin, Nev., February 23, aged 72.

Marcus Henry Slosson, M.D., formerly dean of Pulte Medical College, Cincinnati, died at his home in that city, February 23, from heart disease, aged 85.

Garland Hurt, M.D. St. Louis Medical College, 1863, died at his home in Newport, Ark., Dec. 9, 1903, from pneumonia following influenza, aged 83.

Fred Vernette, M.D. Physio-Medical Institute, Cincinnati, 1865, died from paralysis at his home in Hannibal, Mo., after a long illness, aged 62.

McKendree F. Driscoll, M.D. Starling Medical College, Columbus, Ohio, 1876, died in Chicago from heart disease, January 17, aged 48.

Clinton Toy, M.D. Memphis (Tenn.) Hospital Medical College, 1897, died at his home in Mineral, Texas, from consumption, February 24.

O. Perry Collings, M.D. Tennessee, of Thomas, Okla., died recently in Mexico, where he had gone to spend the winter.

Job Bell, M.D., retired, formerly representative from McNairy County, Tenn., died at his home in Henderson, Tenn., February 25.

William D. McClees, M.D. University of Pennsylvania, Philadelphia, 1885, died at his home in Wichita, Kan., February 25, aged 42.

James P. Richardson, M.D. Columbian University, Washington, D. C., 1868, died at his home in San Francisco, February 9, aged 84.

George W. Gillette, M.D. Tufts College Medical School, Boston, 1902, died at his home in Dorchester, Mass., February 21, aged 25.

William G. Taylor, M.D. Hahnemann Medical College, Philadelphia, 1870, died at his home in Columbia, Pa., March 4, aged 58.

John K. Woods, M.D. Cincinnati College of Medicine and Surgery, 1865, died at his home in Van Wert, Ohio, March 3, aged 77.

Amasa Ward, M.D., died at his home in Hardwick, Vt., from paralysis, after a long period of invalidism, February 20, aged 80.

William E. Schlemm, M.D. University of Pennsylvania, Philadelphia, 1854, died at his home in Reading, Pa., February 23, aged 79.

Asa R. Silvey, M.D. St. Louis College of Physicians and Surgeons, 1890, died at his home in Murphysboro, Ill., recently, aged 47.

Charles W. Newton, M.D. Medical College of Ohio, Cincinnati, 1891, of Toledo, Ohio, died at Phoenix, Ariz., February 2, aged 36.

Anna E. Mills, M.D. Denver, 1903, died at her home in Denver, February 21, from tuberculosis of the intestines, after a long illness.

J. N. Ramsay, M.D. University of Pennsylvania, Philadelphia, 1859, died at his home in Seaboard, N. C., February 26.

David Prescott Merritt, M.D. McGill University, Montreal, 1881, died recently at his home in Elmira, N. Y., aged 63.

Samuel L. Johnson, M.D. 1888, died at his home in Pittsburg, Pa., February 21, after an illness of ten days, aged 77.

John Ashe Mayer, M.D. Atlanta (Ga.) Medical College, 1856, a retired physician of Scarboro, Ga., died February 23.

Wilson Reed, M.D. Hygeio-Therapeutic College of New York, 1861, died recently at his home in Indianapolis.

F. A. Stevens, M.D., of Berwyn, I. T., died from pneumonia at the Gainesville Sanitarium, February 26.

A. F. Pattison, M.D., died at his home in Plattsburgh, N. Y., March 3, aged 76.

Book Notices.

BIOGRAPHIC CLINICS. Volume II. The Origin of the Ill Health of George Eliot, George Henry Lewes, Wagner, Parkman, Jane Welch Carlyle, Spencer, Whittier, Margaret Fuller Ossoli and Nietzsche By George M. Gould, M.D., Editor of American Medicine. Cloth. Pp. 392. Price, $1.00. Philadelphia: P. Blakiston's Son & Co. 1904.

In a previous volume Dr. Gould attempted to convince the medical world—but, as he himself admits, with slight success—that the ill health of De Quincey, Carlyle, Darwin, Huxley and Browning was mainly due to defective eyes. In the present volume a similar line of argument is pursued, but we fear the same jury will also render a Scotch verdict in the case of the fourteen personages under discussion. Postmortem diagnosis is the most valuable of all single methods with a complete *sectio corporis* in evidence, but notoriously misleading, and, may we not add, unscientific when it is based, as in these instances, on quotations from diaries, biographical sketches, incomplete medical reports and occasional letters. It is like diagnosticating and prescribing through the medium of the postoffice or telephone; most of us shrink from it, especially when we have never seen the patient. Naturally, then, we hesitate to agree with Dr. Gould, in whose mind, nevertheless, there seems no shadow of doubt. The fourteen exhibited eyestrain, and should have been treated for it (with glasses), after which their sufferings would have disappeared like mist before the rising sun. In all candor, we believe the author would have roundly denounced any German or any Englishman who might have had the temerity and the misfortune to make such an unscientific use of his imagination.

From our reading of Dr. Gould's book we would be content to say that all of the fourteen presented some symptom or symptoms referable to the ocular apparatus, and that a moiety of them—perhaps eight—might have been helped by treatment of their eyes or they might not. We do not know what the exact defect was in any of these cases, as there was no report published of a proper examination having been made of their eyes, and we can not, therefore, speak with any authority or any real satisfaction. Not so with Dr. Gould. *Ladet Alles in ein Schiff*—they were all, he is convinced, ametropic or heterophoric, or both, and what they needed was just one oculist.

In the case of Parkman, if we were to hazard a guess, we would suggest that his ocular disease was a neurasthenic asthenopia not dependent on ametropia, and not curable by lenses alone. Of course, this guess is of little or no value, but it strikes us as being quite as free from objection as Dr. Gould's guess.

We are, however, less concerned with the assertion that certain illustrious workers in the various departments of intellectual endeavor have suffered with "eyestrain" than with the arraignment of the medical profession, the motif that runs through all the chapters of the book, for its alleged neglect of this "morbid factor" in the production of disease. The prefatory matter in Dr. Gould's book is largely composed of denunciations of his confrères for their astounding ignorance and prejudice in this regard. Evidently speaking as an *amicus curiæ* in this particular, he tells us that (page vi) "the profession must be made to realize the enormity of the mistake it has made in ignoring the truth for the past thirty years. It is more than strange that this professional crime—for such it is—should be most grievous precisely in those medical specialists from whom one would naturally expect the speediest and frankest acceptance. I allude to the neurologists and ophthalmologists. From the former class no word of consent or consideration has reached me, and from the oculists I know of but few who have assented even with qualification." The position occupied by the author in the literary world and his standing as a physician demand that we should at least examine this new doctrine and decide whether we have, unwittingly or not, been guilty of the sins laid at our professional door.

At the outset it is to be noted that several of these fourteen victims of ill health suffered from *migraine*, that this disorder was certainly the chief cause of their disability, and that Dr. Gould regards this form of "sick headache" as essentially of ocular origin. "A few drops of a mydriatic in the eyes will cure it—temporarily, of course, and non-use of the eyes will prevent it; a wrong pair of glasses will cause it and right ones will cure it. Thousands have been cured by the right ones. . . . This mystery and opprobrium of medicine can easily be cleared up whenever any 'scientist' may wish." "Each day of sixteen years and many thousands of patients have convinced me that eyestrain is the almost sole cause of the awful disease sick headache." Dr. Gould may easily understand why the enthusiasm of the neurologist and the ophthalmologist is stilled as he reads these sentences. If there is one fact that has hitherto appeared easy of demonstration in the conduct of cases of migraine it is that the ocular element in them is generally small and that the correction of the ametropia and heterophoria present exerts but a feeble influence on the attacks, and that a complete cure is the exception (perhaps not in 10 per cent. of the cases) by any form of ophthalmic therapeusis. Moreover, almost every neurophthalmologist regards the immediate eye symptoms—phosphenes, scintillating or fortification-scotomata cloudiness of vision, hemiopia, aching of the eyes, etc., as only incidentally related to the visual apparatus.

The distinguished author would also have us believe that quite a respectable percentage of the "night terrors," "bad dreams," and restless sleeping in children are due to eyestrain, and that serious and repeated subconjunctival hemorrhages, biliousness, indigestion, nervousness, insomnia, constipation, irritability and other disorders have been directly induced by the ametropic eyes of the adult, but he refrains from telling us what proportion of these troublesome symptoms are of ocular origin. In his opinion, also, cancer, rheumatism, influenza, coryza, partial paralyses of the hands and arms, erysipelas, pneumonia, tuberculosis and even suicide may result, at least indirectly, from the disturbing influences of this morbific agent. If his contentions are well grounded, we readily admit that Dr. Gould has reason to sound as loudly as possible the eyestrain tocsin if his brethren in the light are to be sufficiently aroused against this hydra-headed monster!

The author, while giving a foremost place to eyestrain in the causation of these symptoms, has little or nothing to say about the production of asthenopia by extraocular agents. Surely the organ of sight is sometimes functionally disturbed by, for example, metabolic disorders, nervous diseases and affections of the neighboring cavities. Are we not to be on the lookout lest we prescribe glasses or oculomuscular gymnastics for the relief of eye symptoms that flow from vices of the digestive, nervous or upper respiratory tract? What about the various infections of the lids and globe, the hyperemia, the chronic conjunctivitis, the blepharitis and the other infections of the anterior segment of the globe? Do they not produce much discomfort when the eye attempts to functionate, and are they not worthy of consideration?

The assumption that the evil results of eyestrain are not well understood by the profession is, in our opinion, entirely unwarranted. Why should we be accused of shutting our eyes to the iteration and reiteration of the main facts of ametropic and heterophoric viciousness that diligent and energetic ophthalmologists have paraded before graduates and undergraduates for the past twenty years, not only in this country, but (Dr. Gould to the contrary notwithstanding) in England and the Continent also? Innumerable articles in medical journals, papers before medical societies uncountable, reprints sent broadcast by the thousand, chapters in all the text-books—what more can Dr. Gould ask? Without prolonging this argument unduly, let us quote from a very elementary text-book for students—the nearest to hand. The statement first made is that the *commonest* symptoms induced by ametropic eyes in their attempts to see normally are "headaches, ocular pains and a sense of fatigue." The manual then adds, as less frequent sequels, "frontal or occipital 'neuralgia,' vertigo, insomnia, nervousness, spots or specks in front of the eyes (muscæ), car sickness, nausea, burning in the eyes or lids, smarting, 'drawing' and foreign body sensations, lachrymation and 'hot eye,' not to mention actual organic alterations in the ocular tissues (ametropic choroiditis, cataract, granular lids, conjunctival hyperemia, styes and blepharitis), due to the chronic vascular changes set up by long-continued efforts on the part of the muscular apparatus to bring about normal vision. *Occasionally* this constant irritation of the central system is responsible for attacks of chorea, epilepsy, migraine, neurasthenia, 'nervous' indigestion, 'biliousness,' and other disorders of the sympathetic system—symptoms that disappear when proper glasses are worn." If we add the blurring of print and mixing of letters and lines in reading, it seems a fair statement of the truth about the matter—doctrine that has been steadily, persistently and uniformly preached in medical journals any day these twenty years. To this array we do not believe that Dr. Gould has added anything new.

There are few propositions in the appended sixty-eight reasons "why glasses did not fit" that most ophthalmologists are not perfectly familiar with, or that they will call in question, except, perhaps, a few statements like this: "No optician ever prescribed a scientifically correct pair of lenses." We are no more in favor of the "oculist-optician" than we are of the druggist who prescribes over the counter, yet we would hesitate to make the assertion that neither had *ever* guessed correctly—because it would not be true.

Again, in his comments on "reasons" 5 to 14, and elsewhere, Dr. Gould insinuates that competent, alert and well-trained ophthalmic surgeons are so rare and the accurate determination of the refractive condition of patients so unusual that a long-suffering public must continue to suffer until his particular methods are more widely adopted. In our slight experience, we have come to a different conclusion, and we shall believe that the average American ophthalmologist is as painstaking, as judicious, as experienced and as successful in his dealings with ametropic and heterophoric patients as are the practitioners of any other branch of medicine.

One more word relative to the comment on "reason number 9." The author says: "The work [of the refractionist] demands too severe and continuous absorption of energy to permit of other interests. Science is too extensive in any one branch, and especially in this one, for the 'universal specialist.' Mastery is not attainable in more than one department. Good refraction prevents the ocular surgical diseases, and it will largely do away with the ophthalmic surgeon." If Dr. Gould had not, under "reason 1," already told us that "the 'eyestrain crank' of to-day not only does not ride his hobby hard, but does not ride it nearly hard enough," we would have reminded him that the chief danger to the specialist is the narrowing effect of his specialty. He is prone to think that *his* microcosmos rounds the whole world of medical science, and he is apt, if all his interest lies in one little corner of that world, to believe it to be the pivot on which the whole universe swings. Already the profession, as well as the laity, are beginning to look askance at the wonderful claims of some pent-up specialties. Let us expand and not contract.

Although the truth, as we see it, does not permit us to agree with Dr. Gould's estimate of the enormous evils of eyestrain, we most willingly and cordially pay him tribute justly his due for the amazing industry he has displayed in gathering the materials for "Biographic Clinics," and for the adroit use of a most eloquent pen. The personal history of his fourteen patients furnishes exceedingly interesting reading. We trust that if there is to be a third volume he will give us more biography and less eyestrain.

FUNCTIONAL DIAGNOSIS OF KIDNEY DISEASE. With Especial Reference to Renal Surgery. Clinical [illegible] Investigations. By Dr. Leopold Casper (Privatdocent [illegible] and Dr. Paul Friedrich Richter (Assistant der [illegible] Berlin). Translated by Dr. Robert C. Bryan, Adjunct Professor Genito-Urinary Diseases. University Medical College, Richmond, Va., and Dr. Henry L. Sanford, Resident Surgeon Lakeside Hospital, Cleveland. Cloth. Pp. 233. Price, $1.50 net. Philadelphia: P. Blakiston's Son & Co. 1903.

This is an excellent little work on the newer methods of determining the functional activity of the kidneys. In all diseases of the kidneys affecting one or both organs, in which surgical methods are under discussion, the necessity of examining the urines obtained directly from each kidney separately is very forcibly and properly emphasized. The attempt, however, to show that no methods of examining the urine are of any value save cryoscopy, and the quantitative estimation of sugar eliminated during a phloridzin-glycosuria, is anything but convincing. That both of the methods mentioned are of great value is true, but that they are the only methods of any value is just as certainly not true, and this can easily be demonstrated by an analysis of the very cases reported to show the contrary. The translators have followed the text closely, at times even to the extent of awkwardness of expression. The work is of great value to all who are doing advanced kidney surgery.

Miscellany.

Objectionable Advertisements in the Lay Press.—A few clear-headed and high-minded managing editors in eastern cities have taken the step of excluding objectionable advertisements, but the example has not seemed to be pleasing to the great majority of their fellows. In justice it must be said, however, that many of the sinners are such through sheer, though inexcusable, ignorance. No one about a newspaper office knows anything about medical matters, and the harm done by such advertisements is not realized.—*Cleveland Medical Journal.* Here is more work for the public press committee of the county medical society.

The Pure Food Bill.

This bill, which is now before the senate, and which has passed the house, provides for the change of the Bureau of Chemistry in the Department of Agriculture into the Bureau of Chemistry and Foods, and its enlargement to meet the needs of the law as hereby enacted. It provides that the shipment or introduction of any article of food or drugs which is adulterated or misbranded into any state or territory from another or from any foreign country is to be prohibited. If anyone shall sell or offer for sale such product he shall be guilty of a misdemeanor and fined not exceeding $200 for the first offense, and not exceeding $300 for every subsequent one or be imprisoned not exceeding one year, or both, at the discretion of the court.

No article shall be considered adulterated or misbranded when packed or prepared for export to any foreign country according to the directions of the foreign purchaser when such packing or preparation is not in conflict with the laws of the foreign country to which it is shipped, but if it is sold or offered for sale for domestic use or consumption it shall not be exempt from the operation of all the other provisions of the act.

The director of the Bureau of Chemistry and Foods shall make such examination as may be required of the specimens of foods and drugs under the regulation of the Commissioner of Agriculture, and it shall be the duty of every district attorney to whom the Secretary of Agriculture shall report any violation of this act to cause proceedings to be commenced and prosecuted without delay for the fines and penalties provided.

Definitions of adulterations, misbranded and of the terms drugs and foods are given in detail. The exceptions are that an article of food which does not contain any added poisonous or deleterious ingredients shall not be deemed to be adulterated in the case of mixtures or compounds now or from time to time hereafter known as articles of food under their own distinctive names and not specially included under definition 4 of this section; that is, if it be not an imitation of or offered for sale under the distinctive name of another article. 2. In case of articles labeled, branded, or tagged so as to plainly indicate that they are mixtures, compounds, combinations, imitations or blends provided the labels show the character and constituents thereof, and nothing shall be construed as requiring proprietors or manufacturers of proprietary foods which contain no unwholesome ingredient to disclose their trade formulas except in so far as it may be necessary to secure freedom from adulteration or imitation, and provided further that no dealer should be convicted under the provisions of this act when he is able to prove a written guarantee of purity, in a form approved by the Secretary of Agriculture, signed by the manufacturer or party or parties from whom he purchased such article; provided also that said guarantor or guarantors reside in the United States. Such guaranty shall contain the full name and address of the party or parties making the sale, and they shall be amenable to the prosecutions, fines and other penalties which would attach in due course to the dealer under the provisions of this act. When in the preparation of food products for shipment they are preserved by an external application applied in such a way that it is necessarily removed before use, the provisions of this act shall be construed as applying only when such products are ready for consumption. The Secretary of Agriculture is directed to fix the standard of food products when advisable, and every manufacturer or seller must be able to furnish within business hours and on tender and full payment of the selling price a sample of such drugs or article of food to any person duly authorized by the Secretary of Agriculture to receive the same. Any manufacturer, producer or dealer who refuses to do this shall be guilty of a misdemeanor, and on conviction shall be fined not exceeding $100, or be subject to imprisonment not exceeding 100 days, or both. Any one convicted is also liable to have to pay the costs and expenses of analysis, etc., beside the penalty imposed.

This act does not interfere with commerce wholly internal in any state nor with the exercise of police powers of any state, but foods and drugs fully complying with all the provisions of the act shall not be interfered with by the authorities of the several states when transferred from one state to another as long as they remain in the original unbroken package, except as may be otherwise provided by the statutes of the United States. Proceedings in case of any violation can be held in any district court in the United States. The proceedings in such a libel case shall conform as near as may be to the proceedings in admiralty except that either party may demand trial by jury in any issue of fact and all such proceedings shall be at the suit of and in the name of the United States. The Secretary of Agriculture is authorized to investigate the character and extent of the adulteration of foods, drugs and liquors whenever he has reason to believe that articles are being imported from foreign countries which by reason of such adulteration are dangerous to the health of the people of the United States, or of kinds which are forbidden entry into or forbidden to be sold or restricted in sale in the countries in which they are made or from which they are exported or which shall be falsely labeled in any respect. The Secretary of the Treasury is authorized to open such original packages and deliver specimens to the Secretary of Agriculture for the purpose of examination, giving due notice to the owner or consignee of such articles, who may be present and have the right to introduce testimony. The Secretary of the Treasury shall refuse delivery to the consignee of any such goods which the Secretary of Agriculture reports to him have been inspected and analyzed and found to be dangerous to health, or of kinds which are forbidden entry into or forbidden to be sold or restricted in sale in the countries in which they are made or from which they are exported or which shall be falsely labeled in any respect either by omission of the name of any added ingredient or otherwise or in regard to the place of manufacture or the contents of the package. This act is to be in force from Sept. 1, 1904.

The Loss of Life in 1903.

Statistics gathered during the year 1903 show that the loss of life in the United States from various violent causes was as follows:

RAILROAD DISASTERS.

The loss of life by railroad accidents during 1903 was 4,090, as compared with 3,165 in 1902, 3,699 in 1901, and 1,409 in 1900. In addition to the loss of life on the steam roads 573 have been killed on electric roads.

MARINE DISASTERS.

In wrecks at sea and on inland rivers and lakes, the total loss of life was 1,935, as compared with 4,200 in 1902, and 2,255 in 1901.

OTHER ACCIDENTS.

The following table gives the loss of life resulting from other disasters of various kinds:

Fires	1,792	Electricity	156
Drowning	2,471	Mines	788
Explosions	736	Cyclones, storms	487
Falling buildings, etc.	474	Lightning	139

Some disasters which caused the largest loss of life were: Cyclones and rock slides in April, 127 persons; cyclones and the Missouri River floods in May, 266; a cyclone at Gainsville, Ga., in June, 80; a South Carolina flood in June, 58; a cloud-burst in Arizona in June, 31; a cloud-burst in Heppner, Oregon, in June, 200; and finally December 30 about 576 lives were lost in the burning of the Iroquois Theater, Chicago.

MURDERS.

During the year there were 8,976 crimes resulting in death by various forms of violence. In 1902 there were 8,834, and in 1901, 7,852. The number killed by burglars, thieves, etc., was 406, while in 1902 it was 333, and in 1901, 193. During 1903 only 53 highwaymen were killed. The causes of these crimes were as follows:

Quarrels	4,952	Resisting arrest	78
Unknown	2,451	Highwaymen killed	53
Liquor	302	Riots	38
Jealousy	228	Self defense	21
By highwaymen	406	Strikes	35
Insanity	140	Outrages	12
Infanticide	254		

In contrast to the 8,976 cases of murder and homicide are the few legal executions, which numbered 123. In 1902 there were 144, in 1901, 118, and in 1900, 119. In Alabama, Missouri and New York there were 11 executions each, in Virginia 10, in Georgia 9, in Mississippi and Pennsylvania 8, and lesser numbers in other states.

LYNCHINGS.

In 1903, 104 persons were lynched, while in 1902 there were 96, in 1901, 135; in 1900, 115, etc. The number has gradually decreased, in 1885 lynchings numbered 184; in 1892, 235. In 1903 18 persons were lynched in Mississippi, 14 in Louisiana, 13 in Arkansas, 12 in Georgia, etc. Illinois and Montana each had 3, the largest number of any northern state. Of the total number of lynchings 12 occurred in the north and 92 in the south, 86 were negroes, 17 were white persons, and 1 a Chinaman; 2 were women. The alleged crimes were as follows:

Murder, 47; criminal assault, 11; attempted criminal assault, 10; murderous assault, 7; unknown offenses, 5; race prejudice, 5; complicity in murder, 5; arson, 4; suspicion of murder, 3; mistaken identity, 3; insults to whites, 2; making threats, 1; refusing to give information, 1.

SUICIDE.

Suicides during 1903 numbered 8,597, as compared with 8,291 in 1902, 7,245 in 1901, 6,755 in 1900, and 5,340 in 1899. Carbolic acid was the most common poison used and poisoning the most common method. This calls attention to the ease with which carbolic acid may be procured and gives emphasis to the agitation for the lessening of this possibility. Altogether 4,050 persons took poison, 3,627 killed themselves by shooting, 370 by hanging, 185 by railroad trains, 54 by jumping from windows and roofs, 15 by fire, 18 by stabbing, 7 by dynamite and 4 by starving. Of the 8,597 cases of suicide in 1903, 5,385 were men and 3,212 women. Among professional men, physicians headed the list, numbering 35, ministers 5, lawyers 4, artists 4, college professors 2, bank officials 12. The causes of suicide were as follows:

Despondency	4,561	Domestic infelicity	628
Unknown	1,454	Liquor	519
Insanity	401	Disappointed love	299
Ill health	384	Business losses	351

These facts concerning the violent causes of death are full of meaning, but the deductions to be made are not essentially different from those of previous years. The physician would be glad to see statistics of epidemics of disease, but these are stated to be not ascertainable with exactness. The above statistics are gathered from various sources. We add the statistics we gathered and published (The Journal, Aug. 29, 1903) of the number killed in Fourth of July casualties: By tetanus, 406; by other injuries, 60; total, 466.

State Boards of Registration.

COMING EXAMINATIONS.

Maine Board of Registration of Medicine, Portland, March 23. Secretary, A. K. P. Meserve, M.D., Portland.

Regular Board of Medical Examiners for Georgia, Atlanta, March 30. Secretary, I. H. Goss, M.D., Athens.

Arizona Board of Medical Examiners, Phoenix, April 4. Secretary, Wm. Duffield, M.D., Phoenix.

Utah State Board of Medical Examiners, Salt Lake City, April 4. Secretary, R. W. Fisher, M.D., Salt Lake City.

Board of Medical Examiners of Montana, Helena, April 5. Secretary, Wm. C. Riddell, M.D., Helena.

North Dakota State Board of Medical Examiners, Grand Forks, April 5. Secretary, H. M. Wheeler, M.D., Grand Forks.

Board of Medical Examiners of the State of California, City Hall, San Francisco, April 5. Secretary, Geo. G. Gere, San Francisco.

Idaho State Board of Medical Examiners, Boise, April 6. Secretary, R. L. Nourse, M.D., Hailey.

Minnesota State Board of Medical Examiners, State Capitol Building, St. Paul, April 5-7. Secretary, C. J. Ringnell, M.D., Minneapolis.

Illinois State Board of Health, Chicago, April 6-8; April 25-27, and East St. Louis, May 4-6. Secretary, J. A. Egan, Springfield.

Rhode Island State Board of Health, State House, Providence, April 7-8. Secretary, Gardner T. Swarts, M.D., Providence.

State Medical Board of the Arkansas Medical Society, Little Rock, April 12. Secretary, J. P. Runyan, M.D., Little Rock.

Missouri State Board of Health, Kansas City, April 12-14. Secretary, W. F. Morrow, M.D., Kansas City.

West Virginia State Board of Health, Clarksburg, April 12-14. Secretary, Hugh A. Barbee, M.D., Point Pleasant.

Vermont State Board of Medical Censors, Y. M. C. A. Building, Rutland, April 13-14. Secretary, S. W. Hammond, M.D., Rutland.

Board of Medical Supervisors of the District of Columbia, Washington, April 14. Secretary, Wm. C. Woodward, M.D.

Board of Medical Examiners for the State of Texas, Austin, April 21-23. Secretary, M. M. Smith, M.D., Austin.

Iowa January Report.—Dr. J. F. Kennedy, secretary of the Iowa State Board of Medical Examiners, reports the written examination, held at Des Moines, Jan. 26 and 27, 1904, as follows: Subjects, 8; questions, 80; percentage required, 75; applicants, 20; passed, 12; failed, 8.

PASSED.

Association News.

WORK OF MEDICAL LEGISLATION COMMITTEE.

The Panama Canal Commission and the Medical Profession.

Many of our readers are aware of the work done by the Committee on Medical Legislation of the American Medical Association to secure the appointment of a medical member on the Panama Canal Commission. The committee sent out a "referendum," February 24, but, as it developed later, too late to be of service. The committee, March 4, sent out a circular letter referring to the matter, which is as follows:

COMMITTEE ON MEDICAL LEGISLATION.

Office of the Chairman: Cincinnati, March 3, 1904.

To the National Auxiliary Congressional and Legislative Committee:—The Committee on Legislation begs leave to report, relative to General Referendum No. 1, that at the time of the meeting of the National Legislative Council at Washington, information was received that appointments on the Panama Canal Commission would not, in any probability, be closed until after March 1. The President was accordingly addressed and a referendum issued February 24. The appointments were, however, promulgated the next morning—too soon for the referendum to have become effective, even if the appointments had not been previously agreed on. That the latter was, however, the case is shown by the letter of the President, as follows:

White House, Washington, Feb. 27, 1904.

Dr. Charles A. L. Reed, American Medical Association, Cincinnati:

The President directs me to state that before receiving your letter of the 24th the commission had been made up. The President had already given the fullest and most careful consideration to the proposal to put a medical member on the commission, and would have been delighted to have met a delegation from your body if the application had been made in time, exactly as he did meet Dr. Osler, Dr. Welch and others, who came before him on this same subject. Of course it was not possible for him to make arrangements to meet such a delegation after the commission had actually been appointed The President assures you that he is in hearty sympathy with the purposes of your Association, and believes that the commission as appointed will conduct its business in a way which will satisfy the medical experts of this country.

Very truly yours, (Signed) WM LOEB,
Secretary to the President

The foregoing letter, so far as the attitude of the President is concerned, must be accepted as entirely satisfactory. The fact remains, however, that the Panama Canal Commission, in its composition, violates the principle that the medical profession must recognize as vital to its own proper status in the community, viz.: Just representation on any and every commission of mixed membership dealing in a large way with the application of medical science to the general welfare. The present circumstance, however, is to be charged to the congress which, by the terms of the law, left but a single appointment in the seven to the entire discretion of the President. It has been deemed best to recognize the situation simply as another example of the forgetfulness of legislative bodies relative to the civic relations and political importance of the medical profession, and to await the organization of the commission and the promulgation of rules governing medical and sanitary administration, before determining whether or not an amendment to the law, making a commission of nine instead of seven members, two of them physicians, ought to be made the subject of a referendum . . .

CHARLES A L REED, Chairman

Philadelphia Clinics in June.

The medical colleges and hospitals of Philadelphia are preparing a series of clinics and demonstrations complimentary to the members of the American Medical Association. These clinics will be given the week preceding and the week following the Atlantic City session.

New Members.

New members for the month of February, 1904:

The Public Service.

Army Changes.

Memorandum of changes of station and duties of medical officers, U. S. Army, for the week ending March 5, 1904:

Moseley, E. B., deputy surgeon general, granted thirty days' leave about March 1, with permission to apply for an extension of three months and to go beyond the sea.

Patton, I. W., asst.-surgeon, extension of leave revoked.

Bourke, James, asst.-surgeon, relieved from temporary duty as attending surgeon and examiner of recruits, Chicago, and ordered to Fort Sheridan, Ill., for duty.

La Garde, Louis A., surgeon, relieved from duty in Washington, D. C., and ordered to the Philippine Division for duty.

Harvey, Philip F., asst.-surgeon general, left Chicago on thirty days' leave, with permission to apply for thirty days' extension.

Chambers, William H., contract dental surgeon, reported February 19 at Atlanta, Ga., for duty in the Department of the Gulf. He was assigned to station at Fort McPherson, Ga., but February 24 went to Camp George H. Thomas, Ga., for a temporary tour of duty.

Sorber, Ord M., contract dental surgeon, having completed his temporary duty at Fort Bliss, Texas, reported February 25 at Fort Clark, Texas, for temporary duty.

Mills, Frederick H., Patterson, Edwin W., Springwater, Samuel A., Burkart, John L., MacDonald, Charles E., Miller, William G., Newton, Ralph W., and Graves, Leonard K., contract surgeons, sailed on the *Sherman* March 1 for service in the Philippine Division.

Mabry, William C., contract surgeon, granted leave of absence for ten days from Columbus Barracks, Ohio.

Ferguson, James B., contract surgeon, left Boise Barracks, Idaho, February 27 for San Francisco, to assume duty as transport surgeon of the *Dix*.

Stoney, Randell C., contract surgeon, relieved from further duty at Fort Screven, Ga., and assigned to permanent station at Fort Hamilton, N. Y., where he has been on temporary duty for some time.

Navy Changes.

Changes in the medical corps of the Navy, week ending March 5, 1904:

Spratling, L. W., surgeon, ordered to report for special temporary duty in the Bureau of Medicine and Surgery, Navy Department.

DeVries, J. C., A. A. surgeon, detached from duty with recruiting party No. 2 and ordered to Recruiting Station, Baltimore.

Janney, W. H., A. A. surgeon, detached from the Naval Recruiting Station, Baltimore, and ordered to duty with recruiting party No. 2.

Taylor, J. S., P. A. surgeon, detached from the Naval Hospital, New York, and ordered to accompany a marine battalion to San Francisco, and thence to the U. S. S. *Relief*.

McCullough, F. E., P. A. surgeon, ordered to the Asiatic station, sailing about March 9.

Strine, H. F., asst.-surgeon, detached from the Naval Station, Olongapo, P. I., and ordered to the *Annapolis*.

Murphy, J. F., asst-surgeon, detached from the *Wisconsin* and ordered to the *Isla de Cuba*.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the period from February 26 to March 5, 1904:

SMALLPOX—UNITED STATES.

Arkansas: Fort Smith, Feb. 13-20, 5 cases.
California: San Francisco, Feb. 14-21, 9 cases.
Colorado: Denver, Dec. 26-Jan. 30, 18 cases.
Delaware: Wilmington, Feb. 20-27, 1 death.
District of Columbia: Washington, Dec. 20-27, 7 cases.
Florida: Jacksonville, Feb. 20-27, 1 case.
Illinois: Belleville, Feb. 6-27, 7 cases; Feb. 20-27, Chicago, 2 cases; Danville, 1 case.
Maryland: Baltimore, Feb. 20-27, 2 cases.
Michigan: Detroit, Feb. 20-27, 1 case; 83 localities, Feb. 13-20, present.
Missouri: St. Louis, Feb. 20-27, 9 cases, 1 death.
New Hampshire: Manchester, Feb. 20-27, 3 cases.
New Jersey: Trenton, Feb. 20-27, 3 deaths.
New York: Buffalo, Feb. 20-27, 1 case.
Ohio: Bucyrus, Feb. 20-27, 3 cases; Cincinnati, Feb. 12-26, 9 cases, 1 death; Cleveland, 20-26, 1 case; Toledo, Feb. 20-27, 1 case.
Pennsylvania: Feb. 20-27, Allentown, 1 case; Johnstown, 2 cases; Philadelphia, 26 cases, 12 deaths; Pittsburg, 2 cases imported; Williamsport, Feb. 13-27, 7 cases, 2 deaths.
South Car[illegible] Feb. 20-27, 6 cases, 1 death.
Tennessee [illegible] 35 cases; Nashville, 15 cases.
Virginia: [illegible] 7 cases.
Wisconsin: Milwaukee, Feb. 20-27, 4 cases.

SMALLPOX—FOREIGN.

Africa: Dec. 1-31, Cape Town, 1 case; Green and Sea Point, 1 case.
Austria: Prague, Jan. 30-Feb. 13, 11 cases.
Belgium: Jan. 30-Feb. 13, Antwerp, 9 cases, 2 deaths; Brussels, 2 deaths.
Brazil: Rio de Janeiro, Jan. 24-31, 29 cases, 19 deaths.
Canada: Quebec, Feb. 13-27, 6 cases.
China: Jan. 9-16, Hongkong, 2 cases; Shanghai, 20 deaths.
France: Nantes, Jan. 1-31, 2 cases; Rheims, Feb. 7-14, 1 case.
Great Britain: Feb. 6-13, Edinburgh, 19 cases, 1 death; Hull, 3 cases, 1 death; Manchester, 1 case; South Shields, 2 cases, 1 death; Jan. 30-Feb. 13, Leith, 5 cases; London, 11 cases.
India: Bombay, Jan. 26-Feb. 2, 10 deaths; Karachi, Jan. 24-31, 1 case.
Java: Batavia, Jan. 16-23, 15 cases, 2 deaths.
Malta: Jan. 16-30, 4 cases.
Mexico: City of Mexico, Feb. 14-21, 16 cases, 8 deaths.
Netherlands: Amsterdam, Feb. 6-20, 7 cases, 1 death.
Russia: Moscow, Jan. 23-Feb. 6, 15 cases, 5 deaths; St. Petersburg, Jan. 30-Feb. 6, 2 cases, 2 deaths.
Spain: Santander, Jan. 8-15, 3 cases.
Turkey: Constantinople, Jan. 31-Feb. 14, 23 deaths.

YELLOW FEVER.

Brazil: Rio de Janeiro, Jan. 24-31, 5 cases, 1 death.
Mexico: Feb. 13-20, Merida, 1 case; Vera Cruz, 1 case.

CHOLERA—INSULAR.

Philippine Islands: Provinces, Jan. 9-16, 219 cases, 163 deaths.

CHOLERA—FOREIGN.

India: Calcutta, Jan. 23-30, 27 deaths; Madras, Jan. 16-22, 2 deaths.

PLAGUE—UNITED STATES.

California: San Francisco, Feb. 8, 1 case bacteriologically confirmed February 27.

PLAGUE—INSULAR.

Philippine Islands, Manila, Jan. 9-16, 5 cases, 4 deaths.

PLAGUE—FOREIGN.

Africa: Port Elizabeth, Jan. 9-16, 2 cases, 2 deaths.
Brazil: Para, Jan. 28-30, 9 cases; Rio de Janeiro, Jan. 24-31, 8 cases, 5 deaths.
India: Bombay, Jan. 26-Feb. 2, 384 deaths; Calcutta, Jan. 23-30, 17 deaths; Karachi, Jan. 24-31, 11 cases, 10 deaths.
Mauritius: Jan. 21-Feb. 4, 45 cases, 32 deaths.

Society Proceedings.

COMING MEETINGS.

Medical Society of the Missouri Valley, Lincoln, Neb., March 24.
Medical Association of the District of Columbia, Washington, April 5.
Tennessee State Medical Association, Chattanooga, April 12.
South Carolina Medical Association, Darlington, April 13.

CHICAGO MEDICAL SOCIETY.

Regular Meeting, held March 2, 1904.

The President, Dr. R. B. Preble, in the Chair.

Hereditary Syphilis.

Dr. Hugh T. Patrick presented a woman 41 years of age, whose trouble dated back to 1899. He saw her in 1901 for the first time. She suffered from dizziness, failure of vision, intense headaches, and considerable mental and physical hebetude. Following this she developed double vision, which lasted for a few months. Acuity of vision diminished rapidly. Some time later she fell and was unconscious for a short time. When she regained consciousness she vomited. A month later she had another fall, and was also unconscious for a short time. During all this time the severe headaches continued. After several months of these headaches, mental hebetude, double vision, and two unconscious attacks, she was removed to St. Luke's Hospital, and on the day following her arrival became unconscious, and remained so for twenty-four hours. She vomited just before she became unconscious. When she regained consciousness, everything looked blurred, and the left side was paralyzed. The arm became weak first, then the leg, and later the face became involved. With the left hemiplegia there was marked sensory disturbance; marked anesthesia, which continued for a considerable time. Two years after the attack, when patient had regained very good use of the left side, there was still considerable subjective trouble on that side, but very little objective trouble. Patient uses the left hand for practical purposes, but it is not as dexterous as it was, and it feels queer. She has complete homonymous hemianopia. The visual field is normal on one side, but gone on the other. As the result of her trouble, the patient has permanent hemianopia, although she has nearly recovered from her left hemiplegia. The patient is absolutely ignorant of any specific infection.

Dr. Patrick presented another case, a woman 21 years of age, whose mother is at present suffering from tabes, with optic atrophy. The oldest child, a son, died about two years ago from general paresis. The next child, also a son, is at present suffering from tabes, with optic atropny. Patient is the third and only remaining child, who, as an infant, had snuffles, and later developed mucous excrescences. Two and a half years ago she had a typical interstitial keratitis, but up to three years ago, aside from the trivial ailments of childhood, she was well. One day, while sitting on the step, she had a sort of stroke without loss of consciousness; became weak on one side, more especially in the face. The next morning she had another stroke which involved all of the right side. This attack was transient. A month later she had another attack of right hemiparesis, which was a little more severe, and three months later a fourth attack, which was very severe, which left her completely hemiplegic on the right side with aphasia. First the face, then the arm and leg became involved. A year and a half ago patient developed typical jacksonian fits. These fits started with twitching and drawing in of the right side of the face, which extended to the arm, then to the leg, after which she had a general epileptic attack. Sometimes the spasm does not go so far. The face and arm may be convulsed, with no loss of consciousness. Sometimes she has a severe attack which terminates in a general convulsion. Attention was called to the defective teeth of the patient. She also has a disseminated choroiditis. Patient showed unmistakable signs of hereditary syphilis, and Dr. Patrick said the question arose whether the two boys inherited syphilis or had it communicated to them as children. Either was possible; but the family showed the relation between specific disease, tabes and general paresis.

Dr. L. Blake Baldwin showed a Chinaman with syphilis. He had treated eleven cases of this disease in Chinamen. He brought the case for diagnosis. As it was difficult to get a history of such cases, he ventured to say that 90 per cent. of the cases of Chinamen who consult physicians have this disease. With this thought in mind he had given all of them iodid of potassium with good results in most cases. When these patients presented themselves with facial paralysis, paralysis of the arm and leg, with large ulcerations on the leg, it was wise to give them iodid of potassium. The patient denied any initial lesion. Dr. Baldwin also showed several other cases.

Dr. Frederick Menge showed three cases. One was a boy 12 years of age who had hereditary syphilis. Patient had an active proliferating gumma in the nose, springing from the septum on both sides, filling the interior meatus and occluding both nostrils. He had also complete erosion of the uvula.

The second case was a young man who had large syphilitic eschars on the soft and hard palates. The uvula was almost obliterated from syphilitic erosions. In this case the infection occurred thirteen years ago, while the erosions caused the scars three years ago.

Dr. George F. Suker showed a boy who had a typical syphilitic head. He had the tripod of Hutchinson; interstitial keratitis, otitis media, and saddle nose, as well as syphilitic rhinitis, bilateral dacryocystitis and stenosis of the lachrymal duct. Patellar tendon reflex was not lost. Patient had what is called the Darier tooth; atrophy of the upper jaw and of the hard palate. Patient had had these affections since the second week of birth. Attention was called to the typical Hutchinson teeth. The boy was a typical example of inherited syphilis.

Dr. E. A. Fischkin presented a patient who gave a history of having had a primary lesion some twelve years ago, the nature of which was not definitely known. Patient said he did not have secondary lesions, but did have mucous patches, and was free from other manifestations of syphilis for twelve years. Patient had been married five years, and had healthy children. About fourteen months ago purpuric spots began to appear on the lower extremities. Three months ago tubercles appeared on the side of the nose, which were circinate in form, gradually enlarged, and finally ulcerated. Patient was put on iodids and given inunction treatment. Soon the whole leg was covered with purpura, but the spots were closer together, particularly on the surface where the ointment was rubbed in. The question arose in the author's mind as to whether he was justified in calling the case purpuric syphilis, or was the purpura due to the toxic effect of the treatment. Against the latter, it should be said that the patient had purpura twelve weeks ago without treatment.

The second case was a girl 15 years of age who presented a typical tertiary, ulcerating syphilid on the leg. Patient also presented syphilitic scars of the type represented by atrophy and pigmentation. The history was entirely negative. The disease was of two years' duration. If she had acquired syphilis, the primary infection must have occurred when she was 12 or 13. There were a number of scars on the leg and a general adenopathy.

Dr. George F. Suker showed two cases of syphilitic iritis. In one the eye was very painful, while in the other there was scarcely any pain. One had a small corneal ulcer. The patient admitted having had syphilitic infection about a year ago, but now had the secondary manifestations of the disease, with marked adhesions of the iris, and excessive proliferation of the pigmentary layer of the posterior surface of the iris, with a large portion of the anterior surface of the capsule of the lens being involved. There was great reduction of sight, with pupillary adhesion. The corneal ulcer was situated toward the nasal side.

Dr. David Lieberthal showed a case of secondary syphilis, and discussed the differential diagnosis between this disease and lupus vulgaris.

Dr. W. L. Baum showed a patient on account of the anomalous action of some scar tissue of syphilitic origin. The man was under treatment at his clinic a number of years ago. At that time he presented himself with a history of specific infection, followed by ulcerations and keloid-like scars. These were hard and firm and projected beyond the surrounding skin. They appeared under treatment, but a feature of unusual interest was that repigmentation had started in the scar tissue. This was generally denied by dermatologists. He was not prepared to offer any explanation for it, but it was contrary to ideas of pathology and the physiologic relations of this process.

Dr. Hugh T. Patrick, after examining Dr. Baldwin's case of the Chinaman, said that it was one of thrombosis of the sylvian artery, with right hemiplegia and aphasia. The patient had exaggerated reflexes and the typical Babinski sign.

KANSAS CITY ACADEMY OF MEDICINE.

Regular Meeting, held Feb. 29, 1904.

General Anesthesia.

The attendance was large, with an unusually large number of visitors present.

Dr. George Seitz read the paper assigned on the program on "General Anesthesia." In general surgical anesthesia complete paralysis of sensibility is required, but different operations demand different degrees of anesthesia. When possible the patient should be prepared by having the bowels moved and the last meal before the anesthesia should be at least six hours previous. It should consist of light food only. The patient's physical condition should be thoroughly studied. In giving the anesthetic it should be purposed to cause as little excitement of the patient as possible and to give the very least amount of ether or chloroform sufficient to produce the desired effect. With chloroform the pulse should not be allowed to fall below 60, and with ether a pulse of 150 need occasion no alarm. The head should be kept turned to one side, and the pharynx and mouth occasionally wiped in order to prevent the inspiration of saliva which, with ether, is secreted in an excessive amount. The occiput should be held well back, no pillow should be used and the jaw held slightly forward. This position facilitates free breathing. The pupil should never be dilated. Esmarch's mask is good, as is also the Allis cone. The latter is hard to keep clean. Mouth gag, tongue forceps, sponge forceps, hypodermics and stimulants must be provided before any anesthesia is begun. In lung diseases, such as bronchitis, asthma, or emphysema, chloroform should be selected. In mitral lesions chloroform should be given. In aortic lesions, aneurism, or atheroma, it is well to begin with chloroform and to continue with either. Degeneration of the myocardium contraindicates any anesthetic. In kidney disease ether is not contraindicated, but many prefer chloroform. For general work and in the vast majority of cases anesthesia induced by nitrous oxid and continued with ether is the best. Dr. Seitz prefers Bennett's apparatus to any other.

The paper was discussed by Drs. Anderson, Fulton, Mallett, Van Eman, West, Lichtenberg, O'Donnell, Hertzler, Gray, Crabill, Beattie, Sloan and Ritter.

Therapeutics.

Gonorrhea.

The following treatment of gonorrhea has been carried out successfully by Dr. David Shoemaker of Truckee, Cal., and he has derived excellent results in a limited number of cases. He sends us the description in order that his method may be tried more extensively. The technic is as follows: "To two quarts of quite warm water, in a fountain syringe, add six ounces of a saturated solution of picric acid; attach a small No. 9 soft rubber catheter to the nozzle of the syringe and proceed to irrigate. In a recent case, allow the flow to begin as soon as the eye of the catheter has passed the meatus, and wash out only the first two or three inches of the urethra. In an old case that has invaded the posterior urethra, detach the catheter, pass it into the bladder and allow the urine to escape, then attach it to the syringe and partially fill the bladder with the solution, directing the patient to retain this as long as he can conveniently. The catheter is then slowly withdrawn until the solution flows back through the meatus, retaining the catheter at the point at which this occurred until the irrigation is completed. The retained fluid in the bladder prevents infection of that organ and is curative if that has already occurred. This solution causes practically no pain, and its strength may be greatly increased without discomfort to the patient. To avoid a disagreeable staining of the operator's fingers, some lubricant should be used on them. In fresh cases it is rare to see a purulent discharge after the first irrigation and in the older cases the improvement is noticeable at once. This solution is never placed in the hands of the patient for use."

The foregoing treatment is certainly definitely outlined, making it of practical benefit.

Asthma in Children.

According to *Rev. de Ther.*, the best remedy for the treatment of asthma in children is belladonna, giving one pill daily of extract of belladonna, gr. ⅛ (.008), or pulverized belladonna, gr. 1/6 ((.01).

The following combinations are also recommended in the treatment of asthma:

℞.	Ext. grindeliæ robustæ			
	Tinct. lobeliæ, āā	gtt. xv	1	
	Tinct. pulsatillæ	ʒss	2	
	Syr. aurantii flor. q. s. ad	℥iii	90	

M. Sig.: To be taken in one or two days.

In the intervals the iodids should be given. The following combination serves the purpose:

℞.	Sodii arsenatis	gr. 1/3		02
	Potass. iodidi			
	Potass. bromidi, āā	gr. xxx	2	
	Tinct. lobeliæ	m. xxx	2	
	Syr. aurantii flor. q. s. ad	℥iv	120	

M. Sig.: One teaspoonful three times a day.

Thrush.

In the treatment of thrush, where there are simply white, isolated, slightly elevated, firmly adherent dots or macules, Dr. E. Graetzer, in *Post Grad.*, recommends repeated cleansing of the mouth with water, especially after meals. Mechanical rubbing with the finger wrapped in fine linen or absorbent cotton—whereby slight bleeding need cause no alarm—will usually suffice. In the confluent form, where the whole buccal mucous membrane down to the pharynx is dark red, dry and covered with numerous white patches or even where large white membrane covers the surface, tonics are indicated, as the patients are usually exhausted or atrophic. The underlying cause, such as diarrhea, must be treated. Locally the mouth must be washed with an alkaline solution, such as sodium borate or a solution of benzoate of sodium, 40 per cent. strength; or salt water, half a teaspoonful of salt to a glass of water. Some authors use potassium permanganate, 1 to 100; or sodium borate in glycerin, 1 to 4. "Sucking bags," containing boracic acid, are of value. A pledget of sterilized cotton, well covered with finely powdered boracic acid *mixed* with saccharin, is wrapped in a small sterilized rag of silk or fine gauze and given to the child to suck and chew on. These bags should be renewed once in twenty-four hours. In severe cases, the author advocates an application of silver nitrate, 1 to 3 per cent., once daily.

As prophylactic treatment, thorough cleanliness of the nipples and breasts must be observed. The breast nipples should be washed with an alkaline solution before and after nursing. The rooms must be well ventilated, general health improved and any gastrointestinal disturbances corrected. In thrush involving the esophagus and stomach the internal administration of resorcin (.5 to 1.00 to 100) is of benefit.

Holt recommends solutions of sodium borate or sodium bicarbonate, ten grains to the ounce, and applied four times daily, observing care not to injure the epithelium. Applications containing honey or syrup must especially be avoided where the disease is produced by irritation of the rubber nipple, feeding by gavage is resorted to for two or three days, under which method improvement takes place more rapidly.

Epilepsy.

In the treatment of epilepsy medicinally, according to Bjorkmann in *Merck's Archives*, the bromids should be pushed to their full physiologic limit. To begin with, he recommends the potassium salt in doses ranging from grains 40 (2.65) to grains 75 (5.00) daily, increasing it to triple the amount if necessary. If the digestive organs rebel the salt may properly be given in Vichy or seltzer water, or the sodium salt may be substituted, given as follows:

℞.	Sodii bromidi	℥ii	60	

Sig.: One teaspoonful in a claret glass of seltzer water before meals and repeated once during the day.

Or the bromids may be given in combination as follows:

℞.	Sodii brom.			
	Ammon. brom., āā	gr. lxxv	5	
	Aq. menth. pip.	℥ii	60	

M. Sig.: One teaspoonful morning and night.

And for children the following combination:

℞.	Sodii brom.			
	Potass. brom., āā	gr. lxxv	5	
	Ammon. brom.	gr. xl	2	65
	Aq. destil.	℥vii	210	

M. Sig.: A dessertspoonful to a tablespoonful three to five times a day, according to the age.

A good combination for adults is the following:

℞.	Pot. brom.	ʒv	20	
	Ammon. brom.	ʒiiss	10	
	Sodii brom.	ʒv	20	

M. Sig.: One-half a teaspoonful dissolved in seltzer water three times a day.

Bromids, according to the author, should always be given before meals, well diluted. Larger doses should be given before the expected paroxysm, which will at least shorten the spell if not abort it. In some cases the bromid may be combined with chloral or opium for a short time only. In cases where a heart tonic is indicated in combination with the bromids the following may be prescribed:

℞.	Infus. digitalis	℥ii	60	
	Sodii bromidi	ʒiiss	10	
	Ol. menth. pip.	gtt. i		06
	Syrupi q. s. ad	℥vii	210	

M. Sig.: One tablespoonful every two hours, to be continued for several weeks.

Or the following may be substituted:

℞.	Infus. adonis vernalis	℥v	150	
	Sodii brom.	ʒiiss	10	
	Olei menth. pip.	gtt. iii		20

M. Sig.: One tablespoonful morning and night.

In cases of idiosyncrasy for the bromids the following containing sodium borate may be substituted:

℞.	Sodii boratis	ʒi	4	
	Aq. destil.	℥v	150	
	Syr. aurantii corticis q. s. ad	℥vi	180	

M. Sig.: One tablespoonful two or three times a day.

During an epileptic attack the patient should be placed in a recumbent position, the clothing loosened about the neck and waist. The tongue of the patient should be protected by placing rubber or cork between the teeth. If status epilepticus is feared, it may be wise to prevent exaggerated convulsions by administering a small amount of chloroform. In petit mal, nitroglycerin is frequently of great service, producing, as it does, a moderate hyperemia of the brain, if the doses are not too liberal, grain 1/100 to 1/50 (.0006-.0012).

The attempt to prevent or check an attack at the appearance of the aura, either by constricting or rubbing the part from which the aura emanates, is sometimes successful.

The following combination, which is recommended by Dr. Daniel R. Brower, seems to be the ideal combination in the treatment of epilepsy:

℞.	Sodii bromidi	ʒx	40
	Ext. solani carolinense flu.	℥ii	60
	Aq. camphoræ q. s. ad	℥iv	120

M. Sig.: One teaspoonful three times a day in water.

To prevent the acne which may be caused by large doses of the bromids *small doses of arsenic may* be added in the form of Fowler's solution or Pearson's solution, two or three drops of either. If a heart tonic is indicated four or five drops of the tincture of adonis vernalis may be added to each dose of the bromid.

The following combination containing chloral is sometimes of service in nocturnal epilepsy:

℞.	Chloralis	gr. lxxx	5	30
	Pot. bromidi	ʒii	8	
	Syr. aurantii	ʒiv	15	
	Aq. menth. verid. q. s. ad	℥ii	60	

M. Sig.: One dessertspoonful at bedtime in water.

Strontium bromid is said to contain a greater amount of bromin than the other salts. It may be given as follows:

℞.	Strontii brom.	ʒv	20
	Sodii brom.	ʒiiss	10
	Aq. feniculi q. s. ad	℥iv	120

M. Sig.: One teaspoonful after meals and at bedtime in water.

Medicolegal.

Dying Declarations.—The Supreme Court of Louisiana holds, in the case of State vs. Brown, that declarations properly considered at the time to be dying declarations do not lose their character as such by the fact that the party making them lives some time afterward.

Permitting Expert Witnesses to Remain in Courtroom.—The Supreme Court of Louisiana holds, in the homicide case of State vs. Forbes, that a ruling of the court permitting expert witnesses to remain in the courtroom during the trial is not ground to set aside the verdict. The rule, it says, is largely left to the discretion of the trial judge.

Liability for Care of Smallpox Patients in Iowa.—The Supreme Court of Iowa says, in the case of Walker vs. Boone County, brought by a physician, to recover for services rendered in taking charge of a pest-house and caring for smallpox patients, after a city board of health had approved his claim, that the mayor and city council of each city in that state constitute a local board of health. And where it is made to appear that smallpox or other disease dangerous to the public health exists, the board has power to make provision for the care of patients, and may remove the same to a separate house, or to a detention camp or hospital. It may provide nurses, needful assistance and supplies, which shall be charged to the patient, or those liable for his support, if able; if unable, it shall be done at the expense of the county. Code, Section 2570. By Code, Section 2571, it is further provided, among other things, that all expenses incurred in the enforcement of the provisions of the Code relating to the public health, when not otherwise provided, shall be paid by the city. The expression "when not otherwise provided," as used in this section, can have relation only to the provision made in Section 2570 for charging matters of expense to the county, as the matter of the expense incident to the enforcement of the laws relating to public health is nowhere else referred to. Now, the reading of the provision in Section 2570 is plain, and the meaning unmistakable. If the patient is unable to pay, and those liable for his support are unable to pay, then the county must bear the expense. The corollary follows that the county can not be made to pay except that the conditions on which its liability depends are made to appear. In this case the record did not disclose that the physician suing made proof that the patients attended by him and those liable for their support were unable to pay. Such being the condition of the record, it followed that the trial court did not err in sustaining a motion for a verdict in favor of the county and entering a judgment against the party suing for costs.

Waiver of Privilege Extends to Future Trials.—The Second Appellate Division of the Supreme Court of New York, in considering, in the case of Schlotterer vs. the Brooklyn and New York Ferry Co., the effect of the provision of the statute that the express waiver of privilege required must be "on the trial or examination," says that the purpose of the statute is to cover the relation of physician and patient with the cloak of confidence. The purpose is to save the patient from possible humiliation or distress, not to enable him to win a lawsuit. If the patient once permit the physician to testify, there is no longer any reason at any time for excluding competent testimony under the plea of public policy. If the patient once voluntarily renounce the protection of the statute, his waiver is everlasting and irrevocable. So it thinks that the purpose of the provision referred to was not to limit the continuous force of a waiver, and thus to permit the patient to use the statute once as a shield and anon as a sword, but by way of further assurance that the waiver had been formally, clearly, and certainly made. Nor does it think that the language of the statute, in the further provision that the waiver "must be made in open court on the trial of the action or proceeding," authorizes a construction which affords the privilege, notwithstanding the reason for its continuance has ceased to exist. it says that it simply means that, when the waiver is made, it must be made in open court on a trial of the action. It thus affords a safeguard that the waiver was duly made, but not a shift of the waiver, once made. And the court holds that a trial was a trial of the action, within the purview of the statute, where it appeared that, after trying her case after a nonsuit, the party suing began anew, but proceeded on the same cause of action against the same defendant.

Impotence and Marriage and Divorce.—The Court of Chancery of New Jersey says, in what is entitled the case of "G—— vs. G——," that cases of impotence are so rare that the rules governing the action of the courts in such cases are not thoroughly settled. In England the notion seems to have been entertained formerly that complete impotence rendered a marriage void from the beginning, precisely the same as would the existence in life at the time of the marriage of an undivorced spouse of one or the other of the parties, or the fact that the parties were related within the prohibited degrees of consanguinity. This is evidenced by the mode in which suits were framed. The English judicial reports show that suits for a declaration of nullity on account of impotence were framed in this wise: A., falsely called B., vs. B. This was the form in suits for nullity for the other two causes mentioned. But the later cases establish clearly the doctrine that contracts of marriage between parties, one of whom is impotent, are voidable, merely. In New Jersey, the legislature, in the revision of the divorce act of 1902, has provided for decrees from the bond of matrimony in cases of adultery, desertion, and incurable impotence, using the following language: "In case the parties, or either of them was at the time of the marriage physically and incurably impotent, or was incapable of consenting thereto, and the marriage has not been subsequently ratified." In a case of impotency the parties have the power to contract, and the marriage is binding for all purposes, unless it is dissolved by a decree of court at the instance of the party having the right to make the complaint. Thus it seems clear that the widow of an impotent husband would be entitled to dower in his estate, in the absence of a decree of dissolution. The ground on which the decree of dissolution is based is not an original incapacity to contract, but the entire and complete failure of the consideration of the marriage contract. Hence the better doctrine is that the contract of marriage is voidable merely, and not void from the beginning. The statute quoted assumes that it may be ratified. But be that as it may, the clear trend of authority, as stated, is that the marriage is not void from the beginning, but merely voidable at the instance of the disappointed party. If that is so, then the correct doctrine is that such party may ratify it. It is suggested with much force that such ratification may result from a long-continued acceptance and enjoyment of the benefits of a merely platonic marriage, so that the disappointed party will not be permitted, after such long enjoyment, to repudiate the contract.

7 Report of Hemorrhagic Septicemia in Animals in the Philippine Islands. Paul G. Woolley and J. W. Jobling.

1. Thoracic Aneurism.—Burt's article is very detailed as regards diagnosis—too much so to be easily abstracted. He notices the leading characteristic symptoms, such as tracheal tugging, physical signs, pain extending down the right arm and dyspnea, and discusses in particular the characteristic differences between aneurism and malignant growths. For treatment he recommends absolute rest, mental as well as physical, and restriction in the amount of food, especially fluid, and iodid medication. All these expedients are intended to favor the deposition of fibrin in the sac. Sacculated aneurisms with relatively small openings are most benefited by treatment. He does not speak well of the use of the introduction of foreign bodies into the sac as a satisfactory method. Three cases are reported, one with recovery, under the potassium iodid treatment.

2. Appendicitis.—Stone calls particular attention to the dangers of retroperitoneal abscess, especially in cases where the appendix points to the left and downward. The symptoms are mainly those of septicemia in addition to appendicitis. Persistent high temperature and quick pulse after appendectomy should always suggest posterior complications, especially when one or two weeks have elapsed before operation. Such symptoms *may disappear*, but not as a rule, and it is important that we should check what may become systemic infection. He sums up the indications as follows:

1. We should consider every "delayed case" with anxiety, lest there should be retroperitoneal infection.
2. We should be careful to give a [illegible] 'n every case of appendicitis ushered in by, or [illegible] or any symptoms of sepsis.
3. If operating in such cases, we should consider retroperitoneal infection as already started and act accordingly. The discovery and proper treatment of such infection is quite as important as the usual intraperitoneal technic.

In view of the possibilities of retroperitoneal infection, we assume a great responsibility by advising non-intervention in appendicitis, and while we often advise delay when we believe the lesions strictly intraperitoneal, yet it would appear that such a course is very unsafe and it should be condemned when we have reason to fear the complications described.

3. Urethral Labia.—Dickinson notices the recent paper by Howard Kelly in *American Medicine*, Sept. 12 and 19, 1903, noticed in The Journal of Sept. 26 and Oct. 3, 1903, pp. 805 and 878, and remarks that he described the same condition in *American Gynecology*, September, 1902. (See The Journal, Oct. 25, 1902, p. 1073.) The so-called urethral labia are not normal protective organs, as Kelly supposed, but are always artificial and pathologic. They occur only when there are hypertrophies at the labia minora and clear-cut evidence of traction, pressure and friction. He considers that they are an enlargement of the anterior portion of the hymen. They have no protective function, but are connected with special sense. The only certain method of cure is section with the cautery wire.

4. Appendicitis.—The new operation described by Ashton consists in pulling out the head of the cecum from the wound, keeping the appendix taut with control ligatures, then packing with gauze and severing the appendix at its origin and closing with a purse-string suture, supplemented by a Lembert suture to prevent leakage. The article is very fully illustrated. The steps of the operation are given as follows:

1. After the appendix has been located and freed from adhesions, the head of the colon is brought within the abdominal incision. A No. 7 braided silk ligature is then tied around the tip of the appendix, the free ends knotted and the loop, which should be about 6 inches long, is held taut by the assistant.
2. A ligature of the same material is now passed through all the coats of the colon, except the mucous, about three-quarters of an inch beyond each side of the base of the appendix. The free ends of the ligatures are then tied, leaving two loops, each 6 inches long, which are used to control the head of the bowel. A purse string suture is now passed through all the coats of the bowel, except the mucous, about a half inch from the base of the appendix.
3. The appendix and head of the colon are now completely under the control of the operator, who keeps the appendix taut by traction on the ligature, which is tied around its tip. At the same time the assistant grasps the loop on each side of the base of the appendix, and by making traction on them holds the head of the colon well within the abdominal incision.
4. The seat of operation is now shut off from the surrounding parts by packing a strip of plain gauze around the head of the colon.
5. The mesoappendix having been previously ligated and severed, a circular incision is made through the serous coat of the appendix about a half inch above its base.
6. The peritoneum is then stripped back beyond the base of the appendix with the scalpel.
7. The appendix is now amputated below its base with scissors curved on the flat.
8. The opening in the bowel is now closed by inverting its edges with forceps as the purse-string suture is tied, and subsequently introducing a mattress suture to guard against leakage.
9. The operator now douches the seat of the operation with warm normal salt solution, and dries the parts with a gauze sponge. The gauze packing is then removed; the control ligatures cut and withdrawn from the bowel; and the head of the colon allowed to sink into the abdominal cavity.

Special Directions.—The control ligatures which pass through the walls of the colon on either side of the base of the appendix must penetrate only the submucous or fibrous coat, because if they enter the lumen of the gut, infection may result from capillary attraction.

From the time the appendix is amputated until the opening in the colon is sutured and the field of operation douched and dried, the assistant must keep the control ligatures taut to prevent the bowel from becoming displaced and infecting the surrounding intestines.

The serous coat of the appendix must be stripped off well below its base so that when it is amputated a portion of the wall of the colon is also removed. This not only thoroughly eradicates all the diseased structures, but it also leaves no redundant tissue to interfere with the close approximation of the edges of the wound. As a matter of fact, under these circumstances, the serous coat usually retracts and partially closes the opening before the purse-string suture is drawn taut. The antiseptic precautions employed during the operation must be thoroughly carried out, as we are necessarily dealing with an open wound of the intestine. Therefore all instruments which come in contact with the seat of operation must be thrown aside at once, and not used again. Thus the knife which is employed to make the circular incision through the serous coat, and the scissors used to amputate the appendix, naturally become infected, and must be discarded at once. A serious mistake is often made from an antiseptic standpoint in operations of this character by using the same sponge several times on the seat of operation. This habit undoubtedly spreads infection and often causes postoperative complications which can easily be avoided. A sponge which has been pressed once against the tissues should be discarded and not used again. If this is not done the pathogenic germs which adhere to the sponge will be scattered over the uninfected areas surrounding the field of operation. In an aseptic [illegible] is, of course, unnecessary, but when as in an [illegible] sponge comes in contact with the contents of [illegible] it is obviously a dangerous practice, and one which must result in jeopardy to the life of the patient.

Variation in the Technic.—If for any reason a purse-string suture can not be used to close the opening in the colon, a Lembert or a Cushing suture may be substituted. The first six steps of the operation are the same as described above, and after amputating the appendix the surgeon then grasps the upper control ligature about an inch from the bowel with the fingers of his left hand to steady the field of operation while the wound is being closed. The sutures are introduced with a small, full curved intestinal needle, which must be held in the grasp of a needle-holder or a hemostatic forceps.

6. Cervical Adenitis.—Bulkeley points out that many cases of cervical adenitis occur in which the importance of avoiding or minimizing the scar is imperative and ordinary measures not advisable. In such cases aspiration or the use of a seton, or both, may prove successful. In case of tuberculous glands, such measures might also be successful, but there are some dangers. When such glands do not subside under medical treatment, excision done with extreme care and reasonably early is the elective method. Neither aspiration nor the use of a seton should be resorted to in such cases involving the deep cervical glands.

13 Hematoma of the Sternocleidomastoid Muscle: A Study of Three Cases. Theron W. Kilmer.

8. **The Surgery of Facial Palsy.**—The surgical treatment of facial palsy by facio-hypoglossal nerve anastomosis is described and discussed by Taylor and Clark. The operation is given in detail, with illustrations, which make it very intelligible. The conditions on which the results of operation depend are numerous. The best result follows in traumatic cases, and the least hopeful prospects are in those due to neuritis, especially when suppurative. In interstitial neuritis, it is well to wait a few months for signs of spontaneous recovery. In traumatic cases the anastomosis should be done at once. At the end of three to six months of treatment in non-traumatic cases, the neurologist can decide the propriety of operating. The degree of atrophy of the muscle is also an important indication; the more atrophy the less hope, therefore the advantage of the use of massage, electricity, etc., from the beginning to keep the muscles in good condition. The technic of the operation must be precise and delicate. The nerves must not be pinched or unduly handled, and the sutures must be fine and involve only the nerve sheaths. Asepsis is imperative, with the least possible amount of scar tissue. The after-treatment is important. The first degree of recovery consists in symmetry of the face during quiescence, without control of the muscles. The next degree consists in the return of volitional control, and the third degree in the return of emotional control. The authors remark on the physiologic association of the two centers of the hypoglossal and facial nerves, as shown in the frequent affection of both in disease. They favor this anastomosis especially on this account. They do not advise complete division of the hypoglossal, but would extend the facial laterally into it, though complete end-to-end nerve regeneration is most active and satisfactory. It, however, entails a permanent paralysis and atrophy of the muscles supplied by the hypoglossal, and they, therefore, do not advise it.

9. **Contracted Kidney.**—Robinson holds that in certain instances uranalysis alone will not enable us to make an exact diagnosis, and we should always consider other clinical signs and symptoms. In contracted kidney complicating acute disease, the outlook sometimes seems serious as far as the urinary symptoms indicate, but he thinks the prognosis is not invariably very threatening from a renal standpoint in spite of this fact. He has verified this very recently in a case of typhoid fever. The low output of urea may occur to an excessive degree at times, not necessarily to be followed by any manifestations of grave importance. It may, indeed, be compatible with many years of life if carefully and judiciously watched and treated.

10. **The Hot Full Bath.**—The hot full bath is here defined by Grosse as a bath above 100 or 102 F. It should cover the whole body to the jugular fossa, and the temperature should be 107 to 108. The patient should enter it slowly so that one or two minutes elapse before he is fully immersed. He should make no unnecessary movements to increase the sensation of heat, and Grosse does not favor the long duration bath. He has never given it higher than 108 or extended the time beyond eight minutes. There is no danger of catching cold after this bath so long as the patient returns within a quarter to half hour to shelter where he can not catch cold. The diuresis is increased. There is anemia of the internal parts with dilation of the arterioles. The heart action is accelerated. When the duration is short, the bath acts as a stimulant to the heart, but if too long continued, it may induce heart failure. Its action is based: 1, On powerful stimulation of the entire nervous system for a brief period; 2, an intense revulsion of circulation tending to hyperemesize the skin and unburden inner organs; 3, a perspiration more abundant than after any other form of bath; 4, a raising of metabolism, and 5, the creation of a sometimes valuable leucocytosis. It is indicated, therefore, whenever we want to incite energetically the metabolism or create a "curative fever," and when there are toxic substances to be eliminated by a perspiration and we wish to remove exudations and stagnations in the internal organs, and lastly, when we wish to energetically incite the entire vital cell activity. It is contraindicated in myocarditis, heart disease, marasmus, when there are fetid masses in the intestines, in case of pus collection anywhere in the body, and whenever, by thickening of the secretions, pus could be retained, as in otitis media, epididymitis, etc., and in all highly febrile conditions. As special indications, he mentions all maladies of the upper air passages, lung troubles, rheumatic diseases and all forms of climacteric troubles, syphilis, some ophthalmic disorders, neuritis and neuralgia. While some authorities consider the hot bath contraindicated in central nervous disease, some more recent neurologists have shown good effects, as in myelitis lumbodorsalis, hemiplegia, progressive pseudoparalysis, etc. Once in a case of locomotor ataxia he advised it, and had trouble in stopping the treatment, as the patient was inclined to overdo. It has also been recommended in some of the infectious diseases, in incipient influenza, infantile convulsions, colics, etc. He suggests the name "Baelz" for the bath, as corresponding with the terms Brand bath and the Ziemssen bath.

11. **Tuberculosis.**—Ransom claims that the x-ray is one of the most efficient therapeutic agencies for deep-seated pulmonary lesions, though he cautions against its employment in recent hemorrhagic cases. The precise manner of action is not known, but it is inhibitive to bacterial life and growth. A number of cases are reported.

12. **Pernicious Anemia.**—Basing his action on the theory of Hunter that pernicious anemia was started by infection from carious teeth and the reports of treatment with antistreptococcic serum, Walsh has tried serum treatment in one case without any satisfactory results. He therefore condemns it, holding that there is no possibility for determining the specific type of streptococcus that is indicated. Its success in septic disorders has been very poor excepting in rare instances.

17 *Thrush. H. Illoway.
18 *Internal Treatment of Diseases of the Bladder. Louis Stern.
19 *Chloroform in Labor. Edwin Ricketts.

14. **The Economic Value of Medical Science.**—Thompson points out the economic advantages that have ensued from advances in medical science, as shown in the better sanitation, the prolongation of life, the increase of its comforts, etc. He thinks the physician should do still more, and that a section might be organized on medical economics and medical sociology in some medical societies. The physician should take a greater interest and participation in public matters.

15. **Rachitis.**—Nathan discusses the theories in regard to rachitis, and especially those based on deficient chlorid of sodium and lack of calcium in the food. He has been able to test the question of the lack of calcium in cases in which he administered salt and phosphate of calcium regularly with-

out specially beneficial effects. From an analysis of a large number of cases treated with monocalcic phosphates as compared with those treated otherwise, he thinks we can conclude that a deficiency in quantity or faulty absorption is not the cause of rachitis. Some anomaly of metabolism, which, besides causing other abnormalities, is inimical to the normal calcification of bone, must form the starting point in our search for the cause of rachitis. How this is induced is difficult to explain, and will be until we have a better understanding of it than we have at present.

16. **Fracture of the Lower Jaw.**—Knapp describes a splint formed by a sort of tin cap over the head, with a gutter in front and above the eye, by means of which the lower jaw can be bandaged in such a way as to give tension upward and forward as is sometimes required. A bandage is passed under the jaw over the gutter in front, giving tension in the proper direction. This splint is easily made, light, and easy of application.

17. **Thrush.**—Illoway points out that this disorder is due to uncleanliness on the part of the nurse or parent, the *Oidium albicans* being readily introduced, and it rapidly propagates in children's mouths. The treatment of the milder forms is easy with hyposulphite or borax, but in the severer forms he has had the best results with a mixture of tincture of iodin and glycerin, ½ dram of the former to 3⅓ of the latter, applied locally to the parts with a camel's hair pencil. Two cases are reported. He thinks the glycerin is an important factor in the treatment. It loosens up the mycelium and makes its removal sure. This plan, he thinks, surpasses any that has heretofore been recommended in its readiness of application and in its harmlessness and rapidity of action.

18. **Bladder Diseases.**—Stern finds that in certain cases of bladder disease where the urine is strongly ammoniacal, urotropin is not decomposed, and hence does not yield up its formaldehyd. He has, therefore, used a new derivative of hexamethylene tetramin, known as helmitol or hexamethylenetetramin anhydromethylene citrate, which has important advantages, being not only less irritating, but more uniform in its action, the reaction of the urine having no effect on its sterilizing action, while it has some pain-relieving quality. Seven cases are reported of its use.

19. **Chloroform in Labor.**—Ricketts advocates the use of chloroform, a few drops on a handkerchief, held so that the patient inhales the vapor, but not allowing it to touch the face, and making sure that the patient has alternating intervals of air alone, to be followed by chloroform mixed with air. The face should not be obscured from the physician. Pulmonary tuberculosis, heart lesions, diabetes and albuminuria are not contraindications. The tendency is to use altogether too much. The patient should inhale in a shallow manner; deep inspiration is seldom necessary.

25 *Use of Formaldehyd as a Preservative in Urine. Frank W. Kenney.
26 *The Comparative Digestibility of Raw, Pasteurized and Sterilized Milk. T. M. Price.

21. **The Static Machine.**—The failure of the static machine in the hands of many physicians is accounted for, according to Brockbank, by the neglect to prevent dampness within the machine. The material he has found best adapted to prevent such interference is fused chlorid of lime, which, however, must be freed from its water of crystallization by thorough baking and then transferred immediately to within the case of the machine. He has seen machines from which the slightest current could not be obtained treated as above described and working perfectly within less than an hour. Another point of importance is to keep all the metal parts clean and brightly polished. The platform should also be clean and have solid glass legs. The ordinary wooden ones with glass foundations are not sufficient, and cause great loss of current. These legs should be kept free from dust, which is liable to act as a conductor for the current, as he illustrates by an instance in his practice. Another thing that affects the efficacy is the imperfect grounding which should be perfect for both poles and also for the electrodes. The dropping of a brass chain from the indifferent pole to the floor is a very inefficient method. He connects his poles with a gas pipe, and for grounding the electrodes he carries a wire to the external water pipe, and in this way has a perfect system of grounding with far better therapeutic results.

22. **Thrombosis of the Cavernous Sinus.**—Roth reports three cases starting from trivial infections; in the first case from a carious tooth, in the second, from furuncle of the nose, and in the third, from one of the upper lip. These illustrate the danger of infectious lesions about the face and the great importance of prophylaxis in treatment. He describes the symptoms, such as high temperature with remissions, chills, profuse perspiration, usually rapid pulse and evidence of dissemination of septic emboli. Headache is an early and prominent symptom. Vomiting occurs from cerebral irritation, and convulsions occurred in one of the cases. The delirium is followed by gradual stupor. The characteristic symptoms and signs of cavernous sinus thrombosis are the results of stasis in the ophthalmic vein and its branches and pathognomonic eye symptoms. Swelling of the eyelids and edema of the skin are the first indications. Bulging of the eye develops soon after, and pressure on the motor nerves gives rise to diplopia. Immobility, photophobia and pain may be present. The pupil is at first small and later fully dilated. All these symptoms are at first unilateral, but gradually spread to the other eye. The treatment seems to be generally unsatisfactory. When the eye symptoms appear the patient is generally profoundly septic. The various operations to relieve the cellulitis and orbital condition that have been suggested have had apparently small results.

23. **Anesthesia.**—White points out the failure of signs of complete anesthesia. The pupil symptoms are not reliable, and the stretching of the sphincter ani is for obvious reasons not applicable in all cases. If deeply anesthetized, the patient remains quiet and breathes naturally, and this seems the most constant sign of all, but is not infallible. Anesthetists need a sign on which they can rely more thoroughly than on those possessed by them at present.

24. **Frontal Sinusitis and Ophthalmoplegia.**—Five cases are reported by Fish illustrating the fact that the most constant symptom of frontal sinusitis is eyestrain or asthenopia consequent to an accommodation paresis. He notes further the fact that internal partial ophthalmoplegia, coming on suddenly, appearing at different intervals and of variable degrees in an emmetropic eye, or one made so by correction, and not otherwise attributable, is very suggestive of sinus involvement, as illustrated in these cases.

25. **Formaldehyd in the Urine.**—Kenney notices the fact that formaldehyd is frequently used as a preservative of urine, and the further fact that it causes, with the Heller test, a reaction analogous to that of albuminuria. He concludes from his study of the subject that it is not advisable to utilize formaldehyd as an artificial ingredient in the urine, as it will help to mislead in making urinalysis. It makes the urine appear albuminous when it is negative, and a typical reaction is not obtained when albumin is present. The reliability of Introna's test (described in The Journal November 14, namely, the use of formaldehyd in albuminous urine as a reagent), is to be questioned, since the effect of formaldehyd on negative urine is the same, though to a more marked degree, than that on albumin in solution, the difference in the color and density of the precipitate being, as Kenney remarks, immaterial. The therapeutic use of urotropin as a causal factor of possible pseudo-albuminuria is a subject he thinks worthy of study.

26. **Milk.**—Price has experimented on calves with raw, pasteurized and sterilized milk. The results were, with one

exception, highly in favor of the raw milk. The use of sterile milk, excepting in one calf, made it impossible to obtain the feces for analysis, scouring being produced. This was retested on 6 calves, 6 others being used as controls with the raw milk; all 6 were thoroughly scoured out by the sterilized milk. This seems to be a little contrary to the usual prevailing ideas, as sterilized milk has been supposed to cause constipation and has been advocated as a cure for diarrhea in calves. He thinks that anything that would make milk harmful and less digestible in the calf, should certainly be looked on with suspicion before it is given to an infant, notwithstanding the wide difference in the digestive organs of the two.

32 *Suppuration of the Maxillary Antrum: with Special Reference to Diagnosis and Treatment. Herbert Tilley.
33 *Alarming Hemorrhage Following Tonsillotomy: Its Cause and Cure. Harmon Smith.

32. Suppuration of the Maxillary Antrum.—Tilley's article is a very complete review of the subject in its various aspects. He concludes that in the vast majority of cases there is evidence to show that dental disease acts as an exciting, or at least, a predisposing cause, and that to dentists we should, therefore, look for the prevention which is better than cure. The diagnosis can be greatly assisted by trans-illumination, and can be rendered absolutely certain by intranasal puncture which sacrifices no tooth, is easy and almost painlessly performed. The treatment resolves itself into two methods: 1, Alveolar drainage which may cure comparatively recent cases, occasionally chronic ones, and give relief in any, and the radical operation which can be called on to cure all cases in which other methods have failed.

33. Hemorrhage After Tonsillotomy.—Smith has collected all the cases of dangerous hemorrhage in the literature, including three of his own, a total of 54, with 6 deaths. He summarizes them all, with his own experience. He has much faith in the tonsillar hemostat of Mikulicz-Stoerk, and has found it almost absolutely necessary in certain cases where he has employed it. It is not always easy to apply it properly. Too much pressure long continued may cause sloughing, but it is a sure means of controlling hemorrhage when it occurs.

41 *Vasectomy. An Argument for Its Therapeutic Use in Certain Mental Diseases and as a Means of Diminishing Crime and the Number of Criminals. C. N. Ellinwood.

34. Traumatic Neuroses.—Brainerd reports two cases in neither of which was there any medicolegal complications, and in which there was no previous history of hysteria and neuroses and no severe concussion. They were cases of pure traumatic neuroses in which neither the advice nor solicitude of the physician nor the suggestions of friends or attorneys had anything to do with the illness. There was no alarm before the injury and no mental shock. The trauma was the exciting cause in both cases, and the same conditions may hold good in other cases, even if there is litigation connected with them.

37. Occipitoposterior Positions.—Cole concludes that occipitoposterior positions are tedious and painful and among the most disagreeable obstetric complications. Early diagnosis is desirable, and there is often a question as to the best method of meeting the disorder. Plenty of time should be given before the use of forceps; in using the latter, traction should be made with the handles as low as possible and pressure on the head be frequently released. The perineum is frequently partially or completely lacerated, and should be repaired at once. He quotes authorities freely in regard to the matter.

41. Vasectomy.—This procedure is advocated by Ellinwood as a regular operation in imbeciles, maniacs and criminals. He thinks it is free from the after-effects of castration, such as mental depression and hypochondria, and is less repulsive to the patient and is equally effective. He reports a case in which it was followed by marked benefit in a youth with maniacal tendencies under sexual excitement.

42 *Chronic Ulcer of the Stomach and Duodenum from a Surgical Standpoint. With Some Remarks on Gastric Cancer. William J. Mayo.
43 Notes on the Requirements of Modern Hospital Architecture. Arthur B. Ancker.
44 *Drainage in Surgery. James E. Moore.
45 London Charities. J. E. Engstad.

42. Gastric Ulcer.—Almost all questions in regard to ulcer of the stomach are in dispute, according to Mayo. The statistics are divergent, and the frequency as reported is very much greater in some countries than in others. The proportion in the sexes is reported variously. Mayo's experience is that large irregular ulcer is more common in adult males, and that seems to be the general observation. Small ulcer, on the other hand, has been more common in women. He divides gastric and duodenal ulcer into four groups: 1. Mucous erosions involving the superficial epithelium; 2, round and fissure ulcers penetrating through the submucous coat, but not involving the muscular and peritoneal coverings except in perforative cases; 3, chronic irregular ulcers involving all the coats and showing evidences of cicatrization in parts; 4, benign obstructions of inflammatory origin. The last group is based on a complication, but can not always be clearly traced to the other known varieties of ulcer. The symptoms of acute perforation and hemorrhage are well known; attacks of pain in case of a duodenal ulcer are often more severe than those of gastric ulcer. Gastric tetany is somewhat rare, but more common than has been thought. As to laboratory methods of diagnosis, excess of hydrochloric acid is the only one that has been found reliable, and this only as corroboratory. Mayo would dilate the stomach, for diagnostic purposes, in cases of pyloric obstruction, simply with air. The tartaric acid and soda method is dangerous. The best practical test for the loss of motility is the findings of remnants of food in the stomach on using the stomach tube before breakfast. The prognosis has been much discussed. The number of cases reported as cured by medical treatment needs some reservations; it is the old story of appendicitis over again, each acute attack a medical cure. The development of cancer on chronic ulcer is a risk, which has of later years become better realized. Atonic dilatation in neurasthenic individuals is mentioned incidentally by Mayo as being sometimes mistaken for organic disease. The indications for the surgical treatment of gastric ulcer are twofold: first, the question of the ulcer itself, and second, the relief of the complicating dilatation, adhesions, etc. Gastro-enterostomy has the widest application, but excision of the ulcer, pylorectomy and pyloroplasty have each a limited field of usefulness, while in hourglass contractions, gastrogastrostomy combined with gastro-enterostomy is necessary to establish a cure. Excision of the ulcer has its disadvantages. He thinks, however, that the radical procedure of Rodman will be indicated in an increasing number of cases, that is, complete excision of the ulcer-bearing area to be followed by independent gastrojejunostomy. This last is the operation of choice, and in Mayo's opinion is best done by the posterior method. All the methods used—Murphy's, the McGraw ligature, Finney's method—he has employed to advantage. In a general way, the anterior method gives a slightly smaller mortality, but a larger percentage of reoperative cases; the posterior method gives the best permanent results, with slightly greater risk. In conclusion, he mentions cancer of the stomach, and remarks that he and his brother have operated on 135 cases in which 34 were radical extirpations. Of the 28 who recovered, the average length of life was over a year. He thinks that in a few years cancer of the stomach will give as good results after excision as breast operations.

44. Drainage in Surgery.—Moore speaks of cases where drainage is necessary, especially in abdominal surgery. Pelvic surgery rarely requires drainage, but when needed, it is best carried out through the vagina. Gauze is the material of choice, except when there is a large accumulation of pus, and a rubber tube may occasionally be required. In operations for appendicitis during the attrack, drainage is always necessary except in the very early stages. He insists on the importance of covering the gauze drain with rubber tissue to avoid adhesions. Many patients have been infected from points where adherent gauze had been removed. He is still in doubt as to drainage in appendicitis in the borderland between the early and late period, where there is a cloudy serum almost indistinguishable from pus and abundant evidence of inflammation outside the appendix. Some surgeons advocate thorough cleansing and closure without drainage in these cases. Moore still employs the cigarette drain, for he has seen patients die from the lack of it. Drainage is necessary in cholecystostomy, and in cholecystectomy he feels safer to use a cigarette drain because the conditions are not so favorable to healing as in chronic appendicitis where he never drains.

48 Some Anomalous Cases of Gastric Disease. John Dudley Dunham.
49 *The Association of Disease of the Tube and Ovary with Appendicitis. Robert H. Sunkle.

46. See abstract 42 above.

47. Cystitis.—Lower finds that the causes of cystitis are multiple, and the treatment depends on the cause. The steel sound is of little use as a diagnostic measure in bladder diseases. The cystoscope is the most reliable.

49. Appendicitis and Adnexal Diseases.—Sunkle reports three cases illustrating the importance of careful examination of the vermiform appendix in all operations involving the tubes and ovaries. The removal of the diseased appendix gives the best chance for complete recovery, saves suffering and further risk and the possibility of future operation. It is not enough to break up the adhesions around the appendix as they may set up disease later. He believes the day is approaching when the appendix will be removed as a routine prophylactic measure whenever the abdomen is opened for any cause.

58 Perforation of the Urinary Bladder by an Appendiceal Abscess. I. S. Stone.

50. Stricture of the Esophagus.—The condition of stricture of the esophagus is dealt with by Eastman, who advocates the use of a flexible, hollow, spiral wound wire bougie with a thin lead core for progressive dilatation. He illustrates the instrument and its method of use. He finds that by this method of gradual dilatation many cases can be cured. The swallowing of weak cocain or adrenal solution will usually facilitate the introduction of any esophageal sound, relieve nausea and prevent peristaltic efforts which may interfere with the passage of the sound. He finds it more advantageous to enter the esophagus with the head of the patient tilted forward instead of backward, as the tissues of the neck are more relaxed in the latter position. Not every variety of esophageal stricture is amenable to this method of treatment, but he thinks it is doubtful whether the sound is not useful at some time in every case of cicatricial stricture.

51. Diverticula of the Esophagus.—Halstead gives a full account of esophageal diverticula, classifying them according to their origin as to traction and pressure and traction-pressure forms, and by their situation, as those at the pharynx, those at the pharyngo-esophageal junction, the border-line cases; those occurring near the middle third of the esophagus, the epibronchial group of Leutgert, and the deep-seated diverticula in which the origin is below the level of the left bronchus, the so-called epiphrenal diverticula. The first group are mostly found on the lateral wall of the pharynx, rarely posterior. Most of the lateral ones are congenital, probably originating from the remains of the third and fourth branchial clefts. Congenital stenosis of the esophagus may be the cause of diverticula, as also trauma and excessive pressure within the pharynx. The symptoms of lateral pharyngeal are on the whole similar to those of pulsion diverticula of the esophagus. Pharyngo-esophageal pulsion diverticula are the most common. They develop exclusively in the median line posteriorly. The etiology of many of these is not clear. Their point of origin is just below the inferior constrictor, the point of least resistance in the muscle fibers. A number of illustrative cases are referred to, as well as those at other localities in the esophagus. The symptoms are usually those of gradually increasing stenosis, generally in later life. The pressure symptoms of an overloaded diverticulum are often prominent; pain after eating, interference with respiration, of the nervous apparatus adjoining, etc. The diagnosis is based mostly on the clinical history, the subjective symptoms and the evidence obtained from the use of a sound. The skiagraph may be sometimes used to advantage by filling the diverticulum with bismuth mixture or by introducing a metal sound or rubber tube filled with shot. In high up cases the esophagoscope is of use. Rumpel's method of using two stomach tubes is also noted. Palliative treatment consists in the persistent use of the sound and stomach tube; the palliative operation of gastrostomy is indicated only when radical measures are impossible. The radical operation consists in removal of the sac, and he reports a case in which this was done, using a purse-string suture of catgut around the neck with the sound in the sac. The sound was then withdrawn and the sac inverted, and at the same time invaginated into the lumen of the esophagus. The purse-string suture was then tied and three sutures of catgut were passed through the neck of the inverted sac. The result was good. His patient was a man of 76, and the diverticulum was reached through an incision from the angle of the jaw to the sternoclavicular articulation.

52. Bronchoscopy.—Schwyzer describes the bronchoscope of Killian and the technic of its use, reporting instructive cases. The illustrations show how far the bronchoscope and forceps were inserted into the bronchus. He thinks the method a splendid help in some cases of foreign bodies.

53. Mixed Tumors of the Salivary Glands.—Wood finishes his paper in this issue. His conclusions are given as follows:

1. There is a group of extremely complicated tumors occurring in the facial region which contain elements from both epi- and meso-blast in most intimate relation to each other. 2. The complicated structure of the stroma, containing as it does elements such as embryonic connective tissue, cartilage, bone, fat and lymphoid tissue, and very rarely striated muscle, is explained most

easily by the assumption of an embryonic misplacement of mesoblast. 3. The structure of the parenchyma is so slightly characteristic in morphology that its epithelial nature in all cases can only be considered as probable; yet in about 24 per cent. of the tumors examined the presence of epithelium is undoubted. The form and relationships of the cells of the parenchyma do not furnish sufficient data to justify these cells being regarded as of endothelial origin. 4. The theory of early embryonic displacement of epiblastic tissue during the process of formation of the parotid and submaxillary glands and the branchial arches may account for many of the morphologic peculiarities of the cells of these tumors, especially the lack of many typical features which we associate with epithelium. The same condition may be seen in the epithelial cells of the congenital moles, in which the epithelium is with difficulty distinguished from connective-tissue cells, owing to its close connection with the stroma of the tumors and its undifferentiated type. 5. The mixed tumors of the salivary glands run a clinical course. strikingly different from th inomata, in that they are slow growing and be regional lymph nodes are not invaded, and to remain local in a considerable proportion

The paper ends with an apparently complete bibliography since 1896.

55. **Abdominal Aponeuroses.**—The important conclusions deduced by Winslow are that the aponeurosis coverings are the chief supporting structures of the abdominal wall; that their approximation by overlapping, in doubling the strength of the aponeurotic layers, doubles the strength of the abdominal incision. This being so, and the overlapping method proving the best method of curing abdominal hernia, it follows that as prevention is better than cure, it is wise to prevent hernia by applying this principle in closing all abdominal incisions. He illustrates the technic.

64 *Blastomycosis of the Ocular Structures, Especially of the Eyelids. Casey A. Wood.

59. **Sympathetic Ophthalmia.**—The pathology and etiology of sympathetic ophthalmia are discussed by Ramsay, who considers that the infection travels by way of the blood stream rather than by the nerves. As regards treatment, he thinks to be most effective it should be prophylactic, and much depends on the manner by which the injured eye has been treated immediately after the accident. In some cases enucleation is unavoidable, and he lays down the following rules: 1. Enucleate at once if the injury is so severe that the exciting eye is destroyed from the beginning. 2. Enucleate at once on the slightest sign of sympathetic irritation if the vision of the exciting eye only equals a perception of light and darkness. 3. Enucleate at once if a foreign body is present and can not be removed from the exciting eye. 4. Enucleate at once when the injured eye is blind and suffering from recurrent acute inflammatory attacks, or when it is tender and irritable as a result of degenerative changes, such as ossification of the choroid. 5. Do *not* enucleate when sympathetic inflammation is in progress and there is still sight in the injured eye, as removal of the exciting eye will then give no benefit, and the probability is that in the end all the sight left will be in the injured eye. He does not favor the substitutes for enucleation that have been suggested, and insists on no operation until all the acute symptoms have subsided. In the beginning we must trust to the ordinary treatment of iridocyclitis. Mercury is the one drug to be relied on, however administered. Its action is intensified by iodid of potassium, which may be given in 10 or 20 grains once a day after meals. The general health must also be attended to. The most that can be hoped for in these cases is that the active symptoms will subside, though in a few cases recovery will follow. If after a year or eighteen months there has been no recurrence of the inflammation and the tension is not diminished and the patient's perception of light is satisfactory, operative interference may be considered, but the iris should be left alone as much as possible. The cataractous lens in these cases should be gotten rid of, and it should be remembered that the vitreous is quite fluid and escapes readily, so the incision should be small. After the operation the eye should be kept bandaged in a dark room, local application of ice used and sedatives internally.

60. **Vision of Railway Men.**—Young has personally investigated the conditions of vision of locomotive engineers and discusses the conditions. He finds some rather paradoxical facts. A lower grade of vision may give better recognition of railway signals than a perfect one. The twinkling, unsteady effect of the effulgent rays, which is exaggerated by the motion of the engine, is in part lost. For semaphore perception the signals ought to be visible for a quarter of a mile, and if the machinery for stopping the train is all right, this ought to be sufficient. The weather, fog, rain and snow produce unfavorable conditions. In snow the brighter the headlight the worse the condition. He thinks that if a smaller parabolic reflector were used, or the light stopped down to a pencil ray through a diaphragm, much of the cloud from reflections from the snow crystals would be dispelled. He favors the use of glasses, holding that if they are prohibited the life of engineers as such will be so short that men will hardly think it worth while to serve the apprenticeship. Examination methods should be as much on the ground as possible, in the yards and along the lines. Tests under unfamiliar conditions should not be given too much prominence. The mental perception of the individual has much to do with the findings. Some persons with perfect vision may be slower in perception than others, and consequently seem more defective. In apprentices normal vision should be required.

61.—See The Journal of February 6, p. 350.

64. **Blastomycosis of the Eye.**—A number of cases are reported from various sources by Wood, who reviews the literature. He remarks that the diagnosis from carcinoma, tuberculosis and epithelioma may sometimes be a little difficult. It is quite possible that a blastomycetic tumor might be mistaken for a syphiloderm. Its comparatively rapid progress, its soft spongy walls, absence of glandular involvement, etc., are, however, usually sufficiently characteristic, and immediate diagnosis may be made by microscopic examination. For treatment, incision with thorough curetting under anesthesia is best. It may be followed by the *x*-rays and the administration of potassium iodid in gradually increasing doses up to 150 grains, as first practiced by Dr. Bevan and later by Drs. Hyde and Montgomery. Some cases will recover without surgical intervention. When it is refused, the dose of potassium or sodium iodid should be continued for three or four months. Local applications are not of much use. He gives the particulars of 6 published and 2 unpublished cases, in addition to one in his own practice.

66 *Senile Dementia; a Clinical Study of 200 Cases with Particular Regard to Types of the Disease. William Pickett.
67 Case of Alexia. Philip Zenner.
68 *Reflexes in Long Distance Runners. A Study of the Influence of Fatigue on Certain Reflexes. Philip Coomes Knapp and John J. Thomas.

66. **Senile Dementia.**—Pickett holds senile dementia is a sort of specific entity, the essence of which is a quantitative change—a mental loss; but the more obvious change is frequently qualitative—excitement, depression and delusion simulating one of the pure insanities. The mental loss, he thinks, is the source and spring of the entire disease. He analyzes a number of cases of the different types of this condition which he considers in legal medicine one of the most important forms of insanity.

68. **Reflexes in Long-Distance Runners.**—Knapp and Thomas have studied the reflexes in the competitors in the Marathon run in Boston. The striking points were the proportion of exaggerated reflexes in the knee and "patellar twitch," in the candidates before the run, and the more or less complete abolition of the same after the performance. The explanation of the increase of plantar reflexes is simple, the increased sensibility of the sole from pounding on a hard road. The diminution of tendon reflexes is not so easy. Exhaustion, as a rule, was not so great as might have been expected, and the most

exhausted cases were not always those which showed the greatest changes. Nevertheless the theory of exhaustion of the reflex centers of the cord seems the most plausible explanation.

72 *Alcohol in Relation to Mental Disorders. Theo. B. Hyslop.
73 The Psychology of the Inebriate Mother. T. Claye Shaw.
74 *The Bearing of Alcoholic Stimulants in Medical Selection for Life Insurance. A. B. Bisbee.
75 *Tea Inebriety Among Children. Matthias Nicoll, Jr.

72. **Alcohol in Mental Diseases.**—Hyslop discusses the effects of alcohol on the nervous system, especially calling attention to the question of alcohol as a cause of paresis. He does not consider it as more than an exciting cause of this disorder, which he believes to be the result of syphilis in most cases.

74. **Alcohol and Life Insurance.**—Bisbee classifies all applicants for insurance as follows: The man who is and always has been a total abstainer; 2, the man, a total abstainer at the present, who has been a drinker; 3, the moderate drinker; 4, the man who is ordinarily temperate, but two or three times a year on special occasions gets intoxicated; 5, the man who has violent outbreaks of intemperance lasting a few days or weeks and is temperate in the interval; and 6, the chronic, steady drinker to excess. The last three classes can be ruled out; there is no place in insurance at the ordinary rates for them. He divides the moderate drinkers into the really moderate drinker and the immoderate moderate drinker. The second of these is the most important. They are generally sober in appearance, and respected men in society, never get drunk, but take more or less liquor at different times during the day, more than they realize or their friends suspect. Their systems are constantly charged with alcohol, which is sure to cause irreparable damage sooner or later. This is the most dangerous class for any company to write. The line of demarcation between them and the really moderate drinker is hard to define; each case must be studied on its own merits, and a decision can be reached only after considering carefully each individual case. Many intemperate men will receive policies in spite of the greatest care; it is impossible always to ascertain the facts. As regards those in the liquor trade he would favor the wholesale rather than the retail dealers, but liquor dealers as a class are not good subjects for life insurance. Any man connected with the liquor trade should be considered uninsurable at the ordinary rates unless it can be proved that his habits are beyond reproach. The only remaining class is the reformed drinkers, and he thinks the only safe working rule is to regard these as unacceptable unless their reform is of at least five years' standing, and it can be shown by trustworthy evidence that they are total abstainers, that the reform took place before the age of forty, and searching medical examination shows that the constitution has not been appreciably injured by past dissipation.

75. **Tea Inebriety in Children.**—Nicoll calls attention to the habit among the poorer classes of dosing children with tea to an extent hardly imagined by those who are not acquainted with the facts. It is often given as a substitute for milk. Its effects are disastrous and its remedy lies in the education of the parents.

76 *Some Observations and Suggestions Concerning Therapeutics in Infancy and Childhood. E. W. Saunders.
77 Burns: Prognosis and Treatment. Laura H. Branson.

76. **Therapeutics in Infancy and Childhood.**—Aside from the difficulty of administering medicines, the therapeutics of childhood is very satisfactory. The child can not mislead, but a thorough understanding of the physical signs and symptoms is necessary. Saunders remarks that the giving of water to infants in hot weather and in fever is neglected, ~~and that in many ways the child is mishandled through ignorance.~~ He has a high opinion of hydrotherapy in infant therapeutics, especially the spray bath, which he prefers to other forms for the elimination of heat. Rest is also a matter of importance in the treatment of children. Inhalations are not used as much as they might be, as, for example, the use of vapor from lime water for catarrhal affections. As for drugs, he follows Young's rule except for some drugs, such as chloral, quinin, calomel, digitalis and pilocarpin, of which he gives larger doses, and heroin and morphin and the like, of which he gives less or bases his calculation on the minimum adult dose. At one year of age one-twelfth of the adult dose is given. On the basis of a child doubling its weight in the first six months and trebling it in a year, he gives at six months two-thirds of one-twelfth or one-eighteenth, and for still younger children one-third of one-twelfth or one-thirty-sixth. In case of chloral, however, he has frequently given 2 grains at three months, with frequent repetitions. Another drug in which he exceeds the rule is antipyrin, giving 1 grain at six months without hesitancy. It should not be continued long. As eliminants he mentions pilocarpin, which should be given early. It will not have its best effect in high temperatures, which should be first reduced, and it should also be avoided in case of weak heart or embarrassment of respiration. Among the antipyretics he specially mentions the external application of guaiacol, which is a ready means of reducing the temperature in many conditions, and also appears to have an analgesic effect. Other drugs mentioned are phenacetin, camphor and veratrum viride in sthenic fevers, one-fourth to one drop, diluted, every half hour. Among the specifics he first mentions quinin, which is sometimes difficult to give to children. In severe or inveterate malarial infection, Fowler's solution, with antipyrin hypodermatically, has proved effective. He also speaks of argyrol in ophthalmia neonatorum, and adrenalin in hemorrhages, and guaiacol carbonate in catarrhal conditions of the upper air passages, and as an intestinal antiseptic. Serum treatment is briefly mentioned. The practice of vaccinating with vaccine virus in whooping cough, in patients not before vaccinated, is, he thinks, a useful measure in some cases. With the advent of vaccinia the symptoms of pertussis often abate.

82 The Hospital as an Institution for Investigation and Instruction. Louis Burckhardt.
83 Report on Tuberculosis Exposition Held Under the Auspices of the Tuberculosis Commission of Maryland in Baltimore. John N. Hurty.

79. **Ultra-Visible Life.**—Novy reviews the infections of which the germs have not yet been detected, and which are beyond the reach of our optical apparatus. One-fifth of a micron is at present about the limit, or 1/125,000 of an inch. Evidence that still further divided material endowed with life may exist is shown by the facts of certain diseases, such as the so-called mosaic disease of the leaves of the tobacco plant, rabies, yellow fever, horse sickness of South Africa, rinderpest, sheep-pox, molluscum contagiosum of birds, the germs of which all pass through the Berkefeld filter. He says we know at the present time of at least ten diseases in which the cause falls within the group of filterable organisms. The question presents itself: "Is it a small stage of an otherwise large organism which passes through, or is the cause filterable in all its stages of development? In the latter case we are clearly dealing with an ultravisible organism, unless indeed the virus should chance to be

dialyzable, in which event we would have the as yet purely hypothetical form of 'soluble life.'" The existence of a minute stage of some organism is illustrated by the trypanosoma of rats, which has a length of seven or eight times that of the diameter of the red blood cell, but a very minute form was produced in artificial culture and the material passed through a Berkefeld filter, and the filtrate reproduced the typical disease with ordinary large forms. He remarks on the difficulty of cultivating protozoa. Bacteria, like weeds, grow anywhere, but protozoa are exceedingly susceptible to their surroundings and changes in osmotic pressure cause them to disappear or undergo marked alteration.

88 Oration Delivered by Dr. W. P. C. Barton in 1821. With Explanatory Note. William Pepper.

84. **Specific Coagulins.**—Loeb describes the specific character of tissue coagulins, each being effective on its own species and to a less extent or not at all in others. He considers that we have a fact of wide significance in this specificity. It does not, of course, apply to all ferment actions, especially not to the common hydrolytic ferments of the digestive organs. Nothing can be said as to the mode of origin of these specific substances. He suggests, however, that they may originate as do the experimentally produced antitoxins and agglutinins, by a kind of autoimmunization, a certain fibrinogen producing a specific coagulin. These specific coagulins seem to be specially adapted to protecting the individual by preventing hemorrhage in so far as just the kind of muscle with which the blood comes in contact in flowing through the wound has a specific influence on the blood, accelerating its coagulation. The specific action is also of interest in the matter of thrombosis, as thrombosis is known to follow injury of the blood vessel wall.

7 The Diminishing Birth-rate and What Is Involved by It, Being an Abstract of the Inaugural Address Delivered Before the British Gynecological Society. J. W. Taylor.

1. **Hour-Glass Stomach.**—Moynihan holds that every case of hour-glass stomach is due to ulceration, entirely rejecting the idea that it may be congenital. There may be perigastric adhesions due to ulceration or gallstone disease; chronic ulceration may produce it through adhesions or through contraction induration in its healing, and Moynihan thinks that spasmodic contraction may have considerable influence. The principal aids to diagnosis are in washing out the stomach and its inflation with gas. The two signs of Ewald are of little importance. A number of cases are reported illustrating the condition. As regards treatment, it is purely operative, though in many cases no single operation will suffice. In the cases reported gastroplasty was done alone in 5, gastro-enterostomy alone in 4, gastroplasty and gastro-enterostomy in 2, gastrogastrostomy alone in 1, and gastrogastrostomy and gastroenterostomy in 2. Both parts of the stomach will have to be relieved by operation.

2. **Congenital Narrowness of the Pyloric Orifice.**—In a number of chronic gastric derangements Maylard has found what seems to him evidence to indicate that a congenital condition of the pyloric orifice was the cause of the disorder. He sums up his remarks by saying:

> 1. There exists a large class of patients in young adult life who owe their chronic gastric trouble to a congenital narrowness of the pyloric orifice. 2. This narrowness is due in many cases to an undue development of the pyloric valve lessening the caliber of the orifice to anything between the normal of 12 to 15 mm., and 2 or 3 mm. 3. The proper treatment is gastrojejunostomy performed with due regard to the normal disposition of the parts after operation.

3. **The Postoperative History of Gastric Cases.**—Moullin has obtained the record of 18 cases which had been operated on for ulcer and carcinoma, and finds points that seem worthy of attention. One of them is concerned with hemorrhage from what are called erosive gastric ulcerations or what he thinks are better described as recurrences. There is no difficulty in arresting the bleeding. The erosion or ulceration may be ligated or it may be excised, and he thinks this has saved life in some cases. He has seen this recurrent ulcer follow gastro-enterostomy. He thinks that whatever the pathologic condition may be it is necessary to distinguish these cases from those of chronic ulceration. In the one the operation is only required when the hemorrhage is dangerous to life. In the other hemorrhage is the indication that ulceration is extending, and a different method of treatment is required from that which it has been receiving. Another point is in regard to adhesions: if they are left when gastro-enterostomy is performed there will always be trouble and pain after eating owing to dragging

on the parietal peritoneum. Simple division is of little or no use, they always re-form. The only way to avoid recurrence is to excise that portion of the stomach wall that is attacked, bringing the cut edges together carefully by means of sutures.

5. **Aseptic Surgery.**—This second lecture of Lockwood's treats of skin disinfection. He has for some years used a mixture of alcohol, water and biniodid of mercury, which he finds most satisfactory. He admits that the question of perfect sterilization is still unsettled, but is inclined to think that practical sterilization of the hands can be performed. His method mentioned above has of late given only 3 septic tests in a total of 111. As regards the use of gloves, he admits that the rubber gloves will suffice, but he has found it impossible to avoid tearing them in operating, and they decidedly dull the sense of touch. If some one could invent gloves which could be sterilized by heat and which would not tear or impair the sense of touch, there would be no objection whatever to their use. The disinfection of the patient's skin is a more difficult matter than that of the surgeon's hands and depends on the region. He would give the regions in their order of most certain disinfection as possible: 1. The limbs; 2, the abdomen; 3, the breast; 4, the neck; 5, the back; 6, the groin and axilla; 7, the scrotum, and 8, the scalp, which is the most difficult. Perhaps when more stringent tests are used the skin will be found septic more frequent than it has been. He makes the remark that wounds in the extremities heal better at a distance from the groin and axilla than nearer to those localities. The methods of skin sterilization, however, are still far from perfect. For buried sutures he thinks there is no better material than twisted silk, and that the peritoneum tolerates them better than any other tissue; the tendons, aponeurosis, ligament nerves and fibrous tissue come next. The muscular tissue is the most intolerant. Carbolic acid silk has a decidedly irritating effect on the skin. A great deal depends on the way the silk is tied. Sterile silk sutures tied tightly in the peritoneum will be tolerated, but this is not the case with muscular tissue. For septic wounds he invariably uses catgut, and it is invaluable for operations about the rectum and perineum. It is also best to use it when the wound is supposed to be tuberculous, and it is advisable to use catgut for the control of hemorrhage in all septic wounds. The difficulty is in making catgut itself absolutely aseptic. As regards silver wire, as recommended by Bloodgood, he has found difficulty in the mechanical irritation which it produces. No matter what trouble was taken to cut the ends of the wire short and turn them down, they altered their position and caused pain. Silver foil, he thinks, is the ideal substance for the exclusion of air and protecting the wounds from gauze. He has continued to use it in conjunction with silk and has been gratified with the results. He favors the use of sponges when they can be made sterile. When a sponge has touched anything infective it should at once be discarded.

6. **Appendix-Abscess in the Rectovesical Pouch.**—The advice given to drain abscess in the rectovesical pouch through the vagina or rectum is criticised by Owen, who maintains that abdominal section in these cases is decidedly the best. There are two serious objections to opening appendiceal abscess through the vagina or rectum; one is that the operator can not tell what he is doing and is operating in the dark, and the second is that the operation may be followed by fecal fistula, which absolutely refuses to close. Another strong point for the abdominal route is the possibility of removing the appendix. He holds that when a person has had one unmistakable attack of appendicitis the appendix had better be resected as soon as the inflammation has quieted down. This is in the line of prophylactic treatment of intrapelvic abscess.

8. **Head Injuries.**—Head injuries are common, but very little attention has been paid to their remote consequences. English has collected the notes of 300 patients whose condition was studied some time after injury. The interval between the accidents and the time of investigation varied from one to twenty years. He classifies them under three heads: 1. Those with no effects; 2, those with slight effects; 3, those with marked effects. Under these heads he was able to classify 200 out of the 300 patients, while the remaining 100 were miscellaneous and could not be thus classified. The 200 were studied in two series of 100 each, and slight or marked effects occurred in 69 per cent. of the first series of 100, and 52 per cent. of the second. Twelve patients died, and in only one of these was the death directly due to the head injury, the patient having been in an asylum for six years. In another case it is possible that death was ultimately caused, but the actual cause could not be ascertained. When last seen the patient was suffering from a severe traumatic epilepsy and mental impairment. It was found that the majority of cases that submitted to a necessary period of mental rest after the injury became well. The reason why so many did not is that the treatment was too short. Owing to the inadequate mental rest, recovery is frequently incomplete after skull fracture, so that there is some element of truth in the popular notion that a man is never the same after a head injury. Miscellaneous cases include mild forms of concussion when there is only temporary loss of consciousness. Grave consequences are more likely to occur from these owing to the neglect of any treatment whatever. The effect on the working capacity was specially studied, and in 86 fracture cases information was obtained. Fifty were able to do the same work as before; 15 were doing lighter work; 7 could do very little, and 6 were totally disabled. In 78 cases where there was no apparent fracture, 51 were working as well as before; 12 were a little impaired in their capacity; 6 were doing lighter work; 4 could do but little; 2 had given up their trade, and three were totally disabled. The form of occupation, of course, has its influence and the greater the responsibility and co-ordination, etc., the greater the difficulty. The beneficial effects of head injuries, English says, are almost entirely confined to the imagination of novelists, but he reports a case in which a fall on the head seemed to have a beneficial effect in chorea. He finds that injurious effects are most likely to result during two periods, early life and old age. In children the higher intellectual faculties are being developed and his experience has not borne out the statement that children recover remarkably well from head injuries. In the aged the powers of recuperation are unequal to meet the conditions. He discusses the symptoms, especially traumatic headache, which is commonly observed; also painful or tender scars, vertigo, changes of disposition, especially irritability, which is a common symptom, the inability for mental and physical exertion, disturbed sleep, and an increased susceptibility to the influence of alcohol, which was observed in all cases. Another symptom is the inability to stand high temperature, which is common after head injuries.

11. **Antistreptococcic Serum in Scarlet Fever, Etc.**—Mackie's conclusions are the following:

> Antistreptococcic serum is of distinct value in a certain number of cases of scarlet fever, particularly in those where the throat lesion is severe and toxemia is going on. 2. Bacteriologic examination will give no sure guide as to the cases in which the serum will be beneficial, therefore it is advisable to give the serum early and to make the bacteriologic examination afterward. 3. The serum ought to be given early in the disease, just as in diphtheria. The longer the disease has lasted before the serum is used the less likelihood is there that it will be beneficial. Antistreptococcic serum is too often brought in with the strychnin and oxygen when it is unreasonable to expect it to do good. 4. If the first dose or two have no effect on the temperature its continuation will probably not be of any value. 5. The serum is liable to produce urticario erythematous rashes. 6. Even in those cases in which it does no good there is no evidence to show that it does harm.

The use of the compound sera in diphtheria was tested in 5 cases; 3, however, were almost moribund; 1 died from heart failure in convalescence and 1 recovered almost miraculously, and Mackie is of the opinion that in all cases of diphtheria where there is evidence of streptococcic infection antistreptococcic serum should be given with some reasonable hope that it may do good.

14. **Cancer in Australia.**—Adams' conclusions from the whole study are as follows:

1. Cancer is not due to a bacterial or parasitic origin. 2. Cancer is a constitutional disease due to a specific or malignant virus originating in the blood and chiefly manifesting itself after 35 years of age, and at its greatest virulence between 50 and 70 years of age. 3. Malignant disease may be congenital and certain forms acquired by infection or contagion. 4. The principal factor in the cause is hereditary tendency. 5. The principal exciting factor is prolonged local irritation acting on a constitution suffering from an inherited tendency or which has been debilitated through want or treatment of one or other of the following diseases in their order of frequency: syphilis, alcoholism, obesity, rheumatism, gout or tuberculous disease. 6. The principal dietetic factors in the cause are sugar, beer and alcohol. 7. The principal hygienic factors in the cause are woods and forests whose dropping foliage decomposing causes stagnation of water; also badly formed streets and defective drainage in cities; and the overcrowding, badly housed and fed population of cities. 8. Cancer is a preventable disease and the absolute cure is only to be found in the means for preventing its exciting causes and completely removing the same. 9. The sanitary indigenous foliage of the following natural orders: (*a*) *Myrtaceæ*, (*b*) *Lauraceæ*, and (*c*) *Coniferæ*, appears to exert a specific influence in rendering the native born population of the countries where they grow almost immune from malignant diseases other than might be caused by prolonged local irritation (the Australian eucalyptus belonging to the *Myrtaceæ* exerts the greatest influence in this direction). 10. A eucalyptus oil obtained by means of a scientific preparation from various species grown in Australia possesses a specific action in arresting the pathologic progress and process of malignant disease. 11. All internal and local treatment of a poisonous or irritating nature should be absolutely avoided, more particularly such local treatment as the *x*-rays and Finsen's light, as they are likely to set up secondary conditions around the site of lesion. Far better is early and prompt removal when the malignant growth is accessible.

My object in writing this article is to throw some further light on the cause of malignant disease and to bring more prominently before the notice of the profession a remedy which, though known in some degree, is, in my experience, insufficiently known and certainly insufficiently appreciated. And while strongly advocating its more general use in the treatment of wounds and specific fevers, etc., it is in relation to its specific effect as applied to the disease of cancer that I would urge the profession to give it a fair trial.

20 *An Attempt to Estimate the Risk of Producing Sympathetic Ophthalmitis by Perforating Injury. James W. Barrett.
21 Fish-bone Extruding Through the Abdomen. W. A. Wood.

17. **Hernia.**—Russell reiterates his former views as to the congenital origin of oblique inguinal hernia, and there being a patent condition of the whole or a portion of the processus vaginalis in these cases. Congenital weakness of the abdominal wall, he thinks, does not exist as a factor, and when it does occur it is acquired from the existence of hernia. The complete removal of the sac done before the abdominal wall has been much weakened is the true curative treatment and the use of a truss, excepting in the case of very young infants, is improper. He now brings forward further evidence in favor of his views and also some presumptive evidence that femoral and direct inguinal hernia may belong in the same category with the oblique variety. He illustrates his paper with schematic diagrams and proposes instead of the use of the term congenital hernia, a substitution of the terms total funicular and partial funicular for those now called congenital and funicular respectively.

20. **Sympathetic Ophthalmitis.**—Barrett reviews the figures of various authorities and concludes that, so far as the evidence goes, the risk of sympathetic ophthalmitis occurring in a case of severe injury with iridocyclitis is certainly not less than 5 per cent. and probably considerably more.

32. **Treatment of Tuberculous Knee Affections with Combined Sclerogenic and Injection Method.**—Lannelongue described in 1891 his method of treating joint affections and hernias by local injection of a solution of chlorid of zinc, as was duly chronicled in The Journal at the time. He called this the "sclerogenic method," and time has confirmed his previous announcements, he says. Of late years he has been combining these injections with intra-articular injection of an oily solution of iodoform and creosote in the proportion of 10 parts iodoform, 2 parts creosote and 40 parts ether to 90 parts olive oil. The patients are cured with surprising rapidity by this combination. In case of a typical "white swelling," he first evacuates the intra-articular effusion by puncture, and then injects about 20 gm. of the iodoform solution, then applies compression and immobilization. A few days to two weeks later, the 10 per cent. zinc chlorid is injected under the periosteum, the needle inserted at various points, the aim being to inject it in the regions containing the blood vessels which supply the synovial membranes and in the fungous lesions along the ligaments. The caustic transforms the fungous tissue, causes sclerosis of the tuberculous tissue, and strangles the colonies of bacilli in a mass of fibrous tissue. It must never be injected into the synovial cavities, as this would cause a violent and useless reaction. Its purpose is to destroy the growing colonies which are always to be found in the parts closest to normal tissue, at the periphery of the spongy growth. The normal tissues which limit the morbid focus are the matrix elaborating constantly the tubercular neoplasm under the influence of the bacillus. By modifying this limiting zone the tuberculous process is walled in, while the iodoform injection kills the germs ensconced in the focus. He calls this combined method the intra-extra-articular, and urges its application in all cases of tuberculous osteo-arthritis of the knee, elbow or wrist, with or without effusion. He thinks that if the vague complaints of children were better heeded, these affections could be diagnosed much earlier, and treatment applied to still better effect in the incipient stages. The technic is described in detail as applied in 3 cases, girls between 11 and 13, with white swellings of long standing, having entailed atrophy of leg muscles. The cure was complete in 2 of the cases in five months, the patients dismissed using the knee freely. The third child is still under treatment. In Lannelongue's service at the Enfants-Malades Hospital this method is now currently applied with most gratifying results.

34. **Surgical Treatment of Peripheral Optic Neuritis.**—Koenig attributes peripheral optic neuritis to some preceding infection, such as la grippe, typhoid fever, gonorrhea, etc. This form is characterized by the absence of vascular stasis and brain disturbances, by the limitation of the edematous infiltration to the optic papilla and by its unilateral development. It is the result of circulatory disturbances limited to the papilla and bulbar end of the optic nerve. As it is impossible to act directly on the posterior pole of the eye, he applies treatment to the anterior pole—knowing the close relationship between the two—and treats the condition by sclerotomy. His experience has been limited but satisfactory with this procedure.

38. **Ovarian Castration in Cancer of the Breast.**—Dumont refers to 4 cases in France in which a mammary cancer subsided after removal of the ovaries. He also cites a large number published in England in which the cancer seemed to be favorably influenced by the castration. On the other hand, no result was apparent in a still larger proportion, and none of the patients was really cured.

39. **Instillations in Case of Hypertrophied Prostate.**—Melun advises to introduce the instillator sound through the larger sound previously inserted into the bladder for lavage of the organ. The introduction is thus rendered much easier and the silver instillations are not painful, as the solution does not come in contact with the urethral sphincter, which is usually very sensitive.

44. **Serum Treatment of the Plague.**—Godinho is superintendent of the isolation hospital at Sao Paulo, Brazil, and states that the antiplague serum made by Dr. Vital Brazil and used there is proving fully as effectual as diphtheria antitoxin in diphtheria. Brazil found that mules bear inoculation with the plague germs much better than horses, and thus uses these animals. Their serum is peculiarly active, and almost invariably cured the bubonic form of the plague in an adult when administered before the third day. It frequently cured as late as after the fourth day, and occasionally after the fifth. The disease is much severer in children. The pneumonic form of the plague is too rapidly fulminating in its course for serum treatment to be effectual. It is also liable to fail in the septicemic form, which Godinho regards as a late form of the previously unrecognized disease. [The Brazilian government was petitioned by the last national medical congress to appropriate funds to defray the expenses of a trip to Europe by Dr. Vital Brazil to demonstrate his method of making serums, especially his serum against snake bites. Some of his results were given in The Journal, xli, page 504.—Ed.]

46. **Ether vs. Chloroform.**—Ether kills by arresting the respiration. The heart continues to beat for a certain length of time, and artificial respiration offers a chance for resuscitation. Chloroform, on the other hand, kills by arresting the heart action. Artificial respiration and other procedures commonly employed in such cases are absolutely ineffectual. The only means of restoring the heart functions are by direct massage of the organ. The results of this massage have not been very encouraging to date, no case being known in which the patient survived more than twenty-four hours after his resuscitation.

47. **The Blondlot Rays—the N Rays.**—These new rays have been mentioned in The Journal recently, page 404. Vitoux describes them in detail, mentioning additional facts in regard to them, such as that certain substances store up these rays and emit them afterward spontaneously. Gold, silver, platinum, zinc, iron, etc., after exposure to the sunshine, to an arc lamp or a kerosene light, which all emit the N rays, absorb them and in turn emit them until the store is exhausted. Molecular compression is peculiarly favorable for the production of these rays. Iron is only a transient source for the rays, but after compression it emits them permanently. Tempered steel is thus a permanent source for the rays. They are subject to polarization, refraction and to the laws of reflection, differing thus from the *x*-rays. It has also been found that sound waves constitute a source for the N rays.

51. **Angioma of Breast.**—The patient in the case reported was a girl of 12. The tumor had been noticed soon after birth, but did not commence to grow until about the sixth year. In the 13 cases on record there was no recurrence after ablation of the breast, which was done as the routine procedure whenever the angioma was not quite superficial. The sexes were about equally represented.

54. **Fever in Appendicitis.**—Cheinisse emphasizes the facts that fever is almost an invariable accompaniment of appendicitis, but it is usually moderate and transient. The gravity of the prognosis increases with the intensity of the fever. When the temperature persists and rises after the fifth day, it denotes the formation of an abscess. The mortality in the cases he has collected averaged 11.5 per cent. in the medical cases with temperature not above 39 C., while it reached 36.3 per cent. in the cases in which there was fever above 40 C. In the surgical cases the mortality reached 35.3 and 75 per cent. The prognosis is dubious also when the pulse rate does not harmonize with the state of the temperature. Another important sign is the difference between the temperature in the axilla and in the rectum when the peritoneum is involved. In case of a suppurative appendicitis, the difference may amount to several degrees. It has been noticed also that the maximum temperature is observed between 9 and 10 p. m. in the severer cases.

58. **Remote Results After Prolapse Operations.**—Jacoby reports the late results in 202 out of 257 cases in which some operation was performed for the relief of prolapse of the uterus. The position of the organ was corrected whenever it was found in backward displacement and involved in the prolapse of the vaginal wall. A proportion of 94.5 per cent. were found permanently cured. Better results were attained with the Alexander-Adams operation than with any other method. The number of permanent cures is higher than those reported from Fehling's clinic (76.9 per cent.), Küstner's (69 per cent.), Schauta's (66.6 per cent.), Baumm's (69.3 per cent.) and Zweifel's (33.3 per cent.). Excessive prolapse after the child-bearing age and the irreducible were treated by total extirpation. Prolapse of the posterior vaginal wall, on ground of old laceration of perineum was treated by Asch's method of perineal plastics, which is described in detail. Plastic conservative operations were preferred whenever possible, and each case was treated according to individual conditions without routine rules.

63. Puerperal Metrophlebitis.—During the last four years 105 women were treated at the Friedrichstädter Hospital for puerperal sepsis with death in 54 cases. All but 3 of the latter came to postmortem, and in 14 cases pure thrombophlebitis was found, in 24 pure lymphangitis and in 13 a combination of both. In all the cases of thrombophlebitis, with one exception, besides the hypogastric and uterine veins, still other veins were involved in the process, including the cava in 3 instances. There was only a single case, therefore, in which Trendelenburg's proposed extraperitoneal ligature and resection of the thrombosed vein could have been applied. This one patient was in too debilitated condition for any intervention to be attempted. The pure thrombophlebitis ran a more chronic course, lasting several weeks or months, while in 16 of the 24 cases of pure lymphangitis the patient succumbed in a few days. In the 13 of the associated form death occurred rapidly in 7 and not until after several weeks in 4. In 14 of the 51 fatal cases the birth had been spontaneous; in 9 there had been spontaneous abortion, in 8 forceps delivery and in 11 operative intervention during or after an abortion. In 9 cases the particulars could not be learned.

64. Symptomatology, Etc., of Extrauterine Pregnancy.—This article is based on study of 233 cases observed at the Berlin Charité. In the 73 cases of abortion 36 recovered after operation and 36 under expectant treatment. One patient succumbed, notwithstanding the operative intervention. In the 47 cases of tubal rupture 5 recovered without an operation, and 11 deaths occurred among the 42 operated on. Runge concludes that hematocele, which was noted in 108 of the cases, had better be treated conservatively whenever possible. He ascribes the etiology to pathologic childbed or chronic gonorrhea.

66. Anesthesia for Extracting Teeth.—Läwen gives the history of anesthesia for this purpose, and recommends injection of a combination of cocain and adrenalin as far superior to all other methods. He mixes three drops of 1 per 1,000 adrenalin to each c.c. of a 1 per cent. solution of cocain. One or 2 c.c. of the mixture are sufficient. The anesthesia thus obtained is much more durable than by other methods, while the intense anemia of the parts favors the intervention, and reduces the toxicity of the cocain. Even in cases of caries and alveolar periostitis, the anesthesia is nearly always perfect, but it is liable to be occasionally imperfect in case of pulpitis.

67. Operations on Tumors in Nasopharynx.—Payr has been much pleased with the ample access afforded by the Kocher technic of resecting both jaws. The disfigurement and functional disturbances caused by the intervention are trivial, while its advantages are obvious. He places the patient on a steep incline with the head raised, but hanging over the edge of the table. This avoids much passive hyperemia, and enables preliminary tracheotomy and ligature of the carotids to be dispensed with. He employs this position likewise for other operations on the upper air passages. He mentions that it is wise to determine the vascularity of polyps in the nasopharynx before operating on them. This can easily be done by examining them after the head has been hanging down.

71. Foreign Bodies in Esophagus.—The statistics presented include a case personally observed and 325 collected from the literature, in which the foreign body was removed by external cervical esophagotomy. The mortality was 21.1 per cent. of the total number, but only 12.6 per cent. of the 55 cases during the last three years. The details of each case are briefly summarized. The most dangerous foreign bodies are stones, bones, false teeth and coins. Pins caused two deaths in the 13 cases in which the operation was performed on this account; coins five deaths in 45 cases, nearly all children, and false teeth, twenty-four deaths in 111 cases. The fatal termination was usually due to lesions from the long sojourn of the foreign body in the esophagus.

77 Zur Methodik des Albumosen-Nachweises. O. Freund.

73. Utilization of Nutrient Enemata.—Bial has tested various nutrient enemata on his own person, and found that the absorption of peptone enemata reached 50.5 per cent., and of the peptone-alcohol, 60 per cent. The formula found most effective at the clinic is 25 gm. each of pept. sicc.; sacch. lact., and absolute alcohol, with ten drops of tinct. op. simpl., and water to 250 gm. Three such enemata are given during the day.

74. Study of Colic.—Meltzer accepts the law that normal peristalsis consists in the contraction of the canal above and relaxation below the point of irritation. When to the contraction above is superadded a contraction below, the result is colic, as the content pressed down from above is arrested by the contracture below. He explains gastralgia by a modification of this law, regarding the contrary innervation as possibly a factor in the pathology of the crises of tabes.

76. Enteralgia and Colic.—Buch ascribes the pain in certain cases of gastralgia and enteralgia to the plexuses of the sympathetic, behind the organs which are apparently the seat of the colic. Pressure on these plexuses in these cases will elicit pain similar to the preceding colics. He suggests the term mesogastralgia for the pains in the lower lumbar sympathetic system, including the aortic and upper hypogastric plexuses, and epigastralgia for those in the upper lumbar sympathetic. He recognizes three varieties of mesogastralgia. In the first there is an almost constant sensation of discomfort in the mesogastrium, and the lumbar sympathetic is in a condition of irritation which entails mesogastralgic attacks on slight provocation. In the second variety, the periods of excessive irritability of the lumbar sympathetic alternate with others of normal conditions, the intervals ranging from a few days to weeks. He thinks this group includes von Leyden's "periodical vomiting" and the gastric crisis of tabes. The third variety is marked by a sudden violent attack occurring in the midst of health and gradually subsiding, but leaving for some time an echo of the previous disturbances. All three varieties have in common a constant overexcitability of the lumbar sympathetic, due to a great number of possible causes. He thinks that this neuralgia of the mesogastric lumbar sympathetic system is a very frequent affection, far more frequent than true bowel colic.

times and in different regions. At the Presbyterian Hospital in New York City during the past decade more than 12 per cent. of all cases of pneumonia have resulted in recovery without any medicine whatever, and the large majority of remaining cases which have terminated favorably have been treated symptomatically, although some of the so-called "specifics" have been given fair trial, such, for example, as large doses of carbonate of creosote, antiseptic inhalations, antipneumococcus serum, etc. Yet the mortality from the disease in that hospital does not vary one way or the other from the general average elsewhere. My personal experience with the creosote treatment in that institution, as well as in the severe alcoholic type of pneumonia which prevails in Bellevue Hospital, has not been convincing, and I have very little faith in its efficacy. It is extremely doubtful, also, whether any form of antiseptic inhalation can act as a prophylactic against the extension of a pneumonic process, much less penetrate an already consolidated lung. I would not be understood as denying the possibility of combating the disease by some specific mode of treatment, but until such remedy can be demonstrated to exist to the satisfaction of the medical profession at large, by repeated successes under varying conditions, it is well to check the enthusiasm born of meager experience, which tends especially to impress the laity with delusive hopes.

Ever since the advent of the grippe in 1890 there has been increased talk of "aborted" pneumonia, i. e., pneumonia cut short by drugs, and there have been many cases this winter the behavior of which as regards their limited physical signs and duration has been, to say the least, atypical, but other germs than the pneumococcus are capable of producing these phenomena, and I have never been convinced that a genuine pneumococcus lobar pneumonia, the original "croupous" or "fibrinous" pneumonia, with all its definite characteristics, can be systematically cut short in full career by any system of treatment at present at our command. There are plenty of mild cases to be seen to-day of influenzal type, in which there is a suspicious patch of apparent consolidation at the base of one lung, or elsewhere, which terminate in resolution of their own accord in two or three days, but these are not the subject of the present discourse. In discrediting any "abortive" treatment of pneumonia I would go still further and discountenance wholly the use of certain drugs which have been strongly recommended, such as the entire coal-tar series and jaborandi or pilocarpin, which I have known to produce edema of the lungs in very short order.

THE USE OF ALCOHOL.

Probably no phase of the topic under discussion has incited more controversy than that of the use or abuse of alcohol. My own tendency is to use it much less abundantly than formerly, and not at all as a routine practice. Many patients do best without it, but with a feeble dicrotic pulse, a dry tongue and a profoundly asthenic condition, it is best to give it, perhaps, to the extent of from four to six ounces of whisky or brandy in the twenty-four hours—seldom more than this. To the aged, alcohol should be given early in moderate dosage, and also to alcoholic subjects. I am aware that there are those who do not prescribe it, even for the latter class of patients, but in the wards of Bellevue Hospital, where the majority of all pneumonia cases are met with in more or less strongly alcoholic subjects, I have repeatedly tried to give it up altogether, but have felt impelled to return to it. As a hospital interne, I have seen whisky given at the rate of an ounce an hour—24 ounces in the day—to patients of this class, and was taught that it was doing good so long as it kept the tongue moist and improved the quality of the pulse and that it was a necessary routine remedy; but the general belief in this regard has been considerably modified, and with the exceptions above noted, it is best to withhold alcohol until there is decided evidence of failing heart action.

EXPECTORANTS.

If a comprehensive statement is to be made in regard to the employment of expectorants in pneumonia, it had best be said that in general they are contraindicated. Many patients do well whose expectoration is trifling—perhaps not more than a few drams throughout, and the symptom is of no prognostic import one way or the other. Expectorants, moreover, are prone to disorder the stomach and interfere with the proper assimilation of nourishment, stimulants and other medicines. There are but two theoretical grounds for their use, first to rid the system of possible toxic material from the pneumonic area of the lung proper, and, second, to rid the bronchi of tenacious secretion which might lessen their lumen and render breathing in the normal lung more difficult. In regard to the first of these factors, during the period of dense consolidation when the patient is usually at his worst, there is but little material capable of expectoration from the solidified lung, and it is not to be expected that the trifling amount of toxic substance which sputum might contain is of any importance in comparison with the main toxemia of the system. The effort of coughing is both exhausting and painful to the patient, and attempts to increase it at this period are not advisable. As the pneumonic exudate softens, the patient is usually far on the way toward defervescence or even convalescence, and it makes little difference whether the exudate is reabsorbed or expectorated. With regard to the second factor in those cases in which there is a somewhat copious tenacious bronchial secretion, the efforts at frequent coughing may prove very exhausting, and although this secretion is presumably incapable of adding to the general pneumonic toxemia, it may be well to aid its removal with one of the ammonium compounds, such as the chlorid or carbonate in some simple cough syrup, like that of wild cherry. In those exceptional cases in which the bronchial secretion is very abundant and partakes of the nature of a bronchorrhea, it may be preferable to attempt to lessen it with small doses of atropin sulphate (gr. 1/200), and by the use of a large mustard paste or of dry cups applied anteriorly when the patient is too ill to be turned. This latter treatment, the atropin and mustard or cupping, is to be recommended also whenever pulmonary edema supervenes.

THE GASTRO-INTESTINAL TRACT.

Gastro-intestinal disorder should receive especial attention in prophylaxis and treatment. The disorder is usually more pronounced in the intestine than in the stomach and has a twofold effect: (1) Mechanical, through abdominal distension or rigidity which embarrasses the respiratory movements; (2) toxic, through absorption of products of malfermentation. The common initial dose of calomel should not be omitted, and the bowels should be subsequently kept active with a non-effervescing saline laxative. Tympanites in pneumonia is as much to be dreaded as in typhoid fever, and should be similarly dealt with by temporarily changing the diet from milk to broths and egg albumin, the administration of salol and a laxative, the use of turpentine abdominal stupes, and the giving of a stimulating turpentine enema, or passage of the rectal tube to promote expulsion of flatus.

Although no special variety of indigestion characterizes pneumonia, the tongue is often foul and the high temperature and toxemia inhibit or alter the normal digestive secretions, and passage of more or less feculent and fermenting stools is common. The symptom of persistent hiccough is most serious, and I have rarely known a patient to recover who presented this complication, for it seems to be due rather to central than local irritation, and can, therefore, only be relieved by anodynes, the use of which may prove deleterious in other ways. In the control of intestinal putrefaction, the main reliance should be placed on laxatives and such antifermentative remedies as salol. Irrigation of the bowel usually is too disturbing to the patient to be undertaken. It is very desirable to insist that the patient drink as much cool water as possible, although this often becomes difficult owing to the presence of delirium or the interference which repeated swallowing produces with respiration.

DELIRIUM.

The control of delirium in pneumonia may become a serious problem, whether it be due to alcoholism or to the disease itself. In mild cases, mild remedies should be first tried, such as the bromids, codein or trional. The latter is a very safe, non-depressing remedy in moderate doses (gr. xv-xx), and it acts particularly well in conjunction with codeia. I have seen serious conditions result from the giving of even small doses of morphin in the delirium of pneumonia. Less than a quarter of a grain may sometimes produce marked increase in cyanosis, and irregular or Cheyne-Stokes breathing. If used at all, it should be combined with atropin and some form of heart stimulant. When the delirium is the outcome of hyperpyrexia, it may be controlled to a large degree by the cold wet pack. With a severe alcoholic delirium or maniacal delirium from any cause, the problem is quite different. The patient is particularly liable to have delusions of persecution and attempt to escape, or he is constantly exhausting himself by shouting and violent jactitation. In such a predicament the only possible chance of recovery lies in preventing the exertion which may culminate in acute dilatation or other enfeeblement of the heart. Paraldehyd, hyoscin hydrobromate and morphin may all in turn have to be used, and in dosage which one does not like to be quoted as recommending, for fear of misinterpretation. The importance should be emphasized of giving digitalis or some other heart stimulant when large doses of depressing hypnotics are required for emergency.

OXYGEN.

The value of oxygen inhalation has been much discussed. The gas is expensive, is easily wasted, and it has acquired so much unfortunate newspaper notoriety that the popular impression prevails that it is used only as a last resource, when all else has failed. In many cases it is certainly of doubtful utility and fails to make any impression on either cyanosis or the embarrassed respiration. Nevertheless, I believe it is often of distinct service, and I do not like to treat a severe case without it. It often relieves subjective dyspnea, and thus has a mildly, soothing effect on the patient; and there are not a few cases in which it produces improvement in objective symptoms as well. It should not be left until the patient is *in extremis*, but, if administered at all, it should be given early and abundantly, and the nurse should be cautioned not to let the patient increase his exhaustion by voluntary efforts at deep inhalation of the gas, or its benefits will be neutralized. It is difficult to explain its value under the laws of the physics of respiration, for there is much unused oxygen returned in the exhaled atmospheric air of normal respiration, but the atmospheric air immediately surrounding a rapidly breathing pneumonic patient is none too pure, and if oxygen acts in no other manner, it certainly supplies a chemically pure air in convenient form without draft or chill. In this connection the importance of maintaining the air about the patient as pure as possible should be emphasized. Gas and kerosene stoves, unnecessary gaslights, like the lungs of anxious friends who insist on crowding into the sick room, not only consume much oxygen, but vitiate the remaining atmosphere with carbon dioxid and other noxious material. In excluding members of the patient's family from the room, it is well to explain to them that this is done, not alone on the ground of securing absolute quiet, but also to insure purity of the atmosphere.

HYPODERMOCLYSIS.

Of recent years the treatment of hypodermoclysis has added a valuable therapeutic measure. In most cases it is to be preferred to direct venous infusion, as the salt solution used is thrown more gradually into the circulation. It has been objected that this method of treatment is liable either to produce pulmonary edema or to injure an already overtaxed heart by increasing vascular tension; and, further, that the small volume of fluid, i. e., relatively small as compared with the total volume of blood in the body, can not dilute the toxins present in the circulation to any appreciable degree. These objections appear to me somewhat theoretical, for with considerable experience with hypodermoclysis in pneumonia, I have yet to see any ill effects follow it. On the contrary, in not a few desperate cases, I have known it to save patients who seemed past every hope of recovery. When the respiration is shallow, intermittent and irregular, cyanosis is extreme, the pulse is scarcely perceptible, and there is coma and complete asthenia, the hypodermic injection into the flanks of 1,000 or even 600 c.c. of hot (110 F.) normal salt solution (0.6 per cent.) will sometimes produce a surprising response, and enable the patient to rally for an hour or two, when the procedure should be repeated. The rectal injection of salt solution may also prove of great service.

LOCAL APPLICATIONS.

Topical applications to the chest wall should be made with the view of promoting the comfort of the patient rather than with any idea of influencing either the inflammation or circulation in the lung. For many years I have given fair trial to all manner of applications to the chest wall, hot poultices, ice poultices, ice packs, mustard pastes, cold wet dressings, the pneumonia jacket of cotton or flannel reinforced by oil silk, and the like, but without acquiring the belief that they have the slightest influence on the course or outcome of the disease. At one time I made a series of experiments to determine the depth at which external thermic agents, both hot and cold, could be made to locally modify deep-seated body temperature. Selecting several patients who had long sinuses resulting from chronic empyema which had been operated on, I inserted specially constructed long-stemmed thermometers for a depth of from six to eight inches into the thoracic cavity. Poultices as hot as could be borne (in some instances at 130 F.) alternating with ice, were applied over the chest wall, but in no instance was the temperature of a deeply inserted thermometer capable of modification more than one-eighth of one degree F. By similar experiments repeated on the cadaver, however, the intrathoracic thermometers were decidedly influenced. The conclusion is justified that so long as the superficial cutaneous circulation is maintained, the constantly moving blood conveys away either the heat or cold of any external application, thereby preventing a deep-seated organ, like the lung, which also has an independent vascular supply, from being influenced.

It can scarcely be maintained that any deep-seated reflex effect called into play through external applications of heat or cold independently of direct transmission of thermal units, is capable of controlling an inflammatory process in the lung. I have emphasized this matter, because it has never seemed to me that any form of topical treatment of pneumonia can influence the lung itself. Such treatment is, however, of great service in relieving those patients in whom pleuritic pain is an important feature. As a rule, heat is more soothing than cold, but there are many exceptions, and one sometimes sees patients who have been made most uncomfortable by being half smothered in heavy hot poultices, the frequent renewal of which produces serious disturbance. Strapping the chest with adhesive plaster, although it relieves the pleuritic pain, materially interferes with careful physical examination of the lung. For the reasons above given, it is my custom to employ no topical applications at all, unless called for by excessive pleuritic pain, when the choice between the use of heat or cold should be decided by the patient's comfort, rather than by routine.

HYGIENE.

The general hygienic treatment of pneumonia is substantially that of typhoid fever, and I shall not take time for its discussion here, for it involves questions which are much less the subject of controversy than the use of drugs. As for diet, with high fever and tongue dried by mouth breathing and heavily coated, milk constitutes the best food, but under more favorable conditions considerable variety may be allowed, and such articles may be given as broths, egg albumin, beef juice, orange juice, kumiss, junket and palatable gruels of various kinds. The care of the mouth should receive as much attention from the nurse as in typhoid fever, for a foul tongue promotes the indigestion which has been above referred to as so injurious, besides making it difficult to swallow, and adding much to the discomfort of the patient. The usual mouth cleansing with hydrogen peroxid and mild antiseptics should be performed.

THE IMPORTANCE OF REST.

Overzeal in the treatment of pneumonia is, I think, more to be criticised than anything else. This includes overstimulation of the heart, overuse of expectorants, and above all incessant "fussing" about the patient, who, in the well-intentioned but ill-advised efforts of his care-takers, is often allowed scarcely ten minutes in the day for repose. I was lately called to see a physician in desperate plight with double pneumonia, whose brother practitioner was giving him frequent stimulating hypodermic injections, whose nurse was constantly administering expectorants and stimulants in the intervals of renewing poultices and supplying oxygen, whose wife was aiding by giving cold sponge baths literally every fifteen minutes (!), and whose anxious family were frequently looking in at the door to inquire how he felt.

It takes some courage and much experience not to overdo in the treatment of pneumonia. There is no other disease in which the idea of combat against the elements of death presents so active and intense a clinical picture. The picture changes from hour to hour, the time for combat is brief, and no matter how severe the odds against life may appear, there is always a chance, what one terms the "fighting chance," up to the patient's very last breath. Hence, the temptation for active interference may outweigh one's calmer judgment, and the patient may lose through exhaustion that modicum of strength which might at the last moment have turned the balance in his favor. It may seem somewhat trite, but experience shows that it is not so, to insist that proper intervals of absolute rest, of two or even three hours, should constitute a definite part of the treatment. The giving of medicines, food and stimulants, as well as all remedial measures, should be so carefully outlined for the nurse that there be no mistake on this point, and during each twenty-four hours there should be several such periods for rest prescribed. An hour's sleep will often do more to save the patient's life than all the medication he has received throughout the disease, and there are times when it should be remembered that "they also serve who only stand and wait."

CONCLUSIONS.

I am well aware that there is much more to be said regarding the treatment of pneumonia, but I have purposely confined these remarks to the emphasis of what has seemed most satisfactory in my individual work, leaving for others the expansion of the topic. It has always seemed to me that good nursing and the exercise of constant watchfulness should outweigh polypharmacy and specifics.

In closing this brief outline of treatment, I would emphasize certain conclusions as follows:

1. The importance of not crowding an overtaxed heart with too much stimulation, and especially of basing the selection of the proper variety of cardiac stimulant on the existing balance between the conditions of vascular tone and the effort the heart is already making.
2. The uselessness of the so-called "specifics" for pneumonia, and, as a rule, of expectorants.
3. The importance of prevention of indigestion and particularly of tympanites.
4. The great value of hypodermoclysis in certain cases.
5. The uselessness of topical applications excepting for the purpose of relieving pleuritic pain.
6. The necessity of prescribing proper intervals of rest in which the patient is free from incessant efforts at medication.

DISCUSSION

Dr. George L. Peabody believed that intelligent symptomatic treatment was the general attitude of the profession. In violent, uncontrollable, maniacal delirium the cold bath acted very well as a sedative, and he had no doubt that he had often saved life thus when death seemed imminent. A confusion of ideas exists regarding morphin. It does not affect the peripheral but only the central respiratory act and, in pneumonia, the central respiratory function is not at fault. He prefers paraldehyd or amylene hydrate to sulfonal or trional when a hypnotic is needed. It can be given in peptonized milk or by rectum, and a large quantity of the vehicle should be given. For some time past he has been treating cases of pneumonia with salicylates, preferring aspirin because better borne by the stomach. He has so treated 60 or 70 consecutive cases and aspirin certainly had an influence on the disease as proved by the fact that defervescence took place by lysis in 32 per cent. of the cases. He was skeptical regarding any so-called abortive treatment. He looked on hiccough as a bad symptom. If severe and persistent, with high arterial tension, inhalations of amyl nitrite have given him good results. He advocated oxygen if used early and abundantly before signs of cyanosis appear. Locally he approved of the electric warm pad.

Dr. L. A. Conner said that the treatment at the Hudson Street Hospital was purely symptomatic; unless stimulants were really demanded the patients received none; diet was milk, and an abundance of water was given. Not one-quarter as much alcohol is given now as three or four years ago, and without less satisfactory results. During the past two years one-half the patients with pneumonia had been placed on carbonate of creosote, and he hoped eventually to be able to present some statistics regarding the effect of this agent. Emphasis was laid on the importance of watching the abdomen, especially the tympanitis, which was more serious in pneumonia than in typhoid fever. Turpentine stupes were applied frequently and colon irrigations of hot and cold fluids, administered alternately, seemed to give the best results. Pulmonary edema was best treated by dry cupping frequently done.

Dr. Charles E. Quimby believed that keeping a uniform temperature to the body surface had a beneficial effect on the circulation in the lungs. Dry cough could be often relieved by dry friction. He thought it wise to have the temperature of the room above 80 degrees at all times, and the air full of moisture.

Dr. Morris Manges thought that the statistics from the Massachusetts General Hospital, covering nearly 100 years, showing an average mortality of between 10 and 11 per cent., were not reliable because they exclude pneumonias occurring in the young and aged. Wells' statistics, amplified by Osler, give a more correct mortality of 20 per cent. These latter statistics were taken from all over the United States, and embrace 255,000 cases. The routine examination of the abdomen he believed to be of more importance than the routine examination of the lungs. Paralytic distension of the bowels was not alone due to the intestinal contents, but also to a septic process. Cases in which there was no relief of the tympany were beyond the reach of local treatment. He cautioned against the use of even mild cathartics in abdominal distension. especially when of septic character. Venesection he believed to be of value in some cases, especially sthenic. Guaiacol had been of value in his hands in catarrhal pneumonia associated with grippe. Sodium salicylate seemed to act well in children. He did not use morphin in pneumonia, although tentatively he had tried heroin, but without satisfactory results.

Dr. Edward W. Lee emphasized the importance of hypodermoclysis, especially in pneumonia, following operation.

Dr. Alexander Lambert referred to ergot as an equalizer of the circulation, constricting the dilated blood vessels; he had used it with benefit in alcoholic and other pneumonias, in the tympanitic distension in both adults and children, and in edema of the lungs, especially when associated with dry cupping.

Dr. Gilman Thompson said that pneumonia often followed surgical operations because of the lowered vitality. The pneumococcus was present in one out of every five normal mouths, so that the opportunity for the disease to develop was always present under certain circumstances. The respiratory difficulty was the result of the action of toxic material contained in the blood acting on the respiratory center in the medulla. This was proved by the fact that when defervescence occurred the cyanosis cleared up, etc., when the lungs were not yet entirely resolved. The dyspnea was distinctly of central origin, and due to the poison contained in the blood. If the cerebral centers were overwhelmed with the poison morphin would then be injurious.

TUMORS INVOLVING THE CAUDA EQUINA,

WITH REPORT OF CASE.

GEORGE GILBERT DAVIS, A.B.
From the Laboratory of Surgical Pathology of Prof. N. Senn, Rush Medical College.
CHICAGO.

Tumors involving the cauda equina or causing symptoms by pressing on the cauda may have their origin either within the contents of the meninges, i. e., in the nerve trunks of the cauda or in the meninges themselves, or in the structures outside of the dural sheath, especially in the vertebral column.

Tumors having their origin within the cauda itself are not numerous. In a case reported by Volhard,[1] with typical symptoms, a diagnosis of neoplasm of the cauda equina was made and operation decided on, but the patient came to autopsy before it could be performed. A glioma was found close below the conus medullaris, compressing the roots of the cauda against the lumbar vertebræ.

A second case was reported from the service of Dejérine[2] at the Saltpetrière in 1895, and presented the symptoms of compression of the cauda equina. Operation was attempted by Chipault, but was unsuccessful, and the patient died three hours after the completion of the operation. A small-celled sarcoma of the cauda equina was found. Neurofibromatosis of the cauda equina occurs in connection with neurofibromatosis of other parts of the nervous system. Five cases were collected by Thomson,[3] and reported, respectively, by Hürthle and Nauwerck,[4] Küpferberg,[3] Leboucq,[3] Nélaton, Houel,[3] and Soyka.[5] Two cases of malignant growth, one a sarcoma of the cauda equina fibers, the second a fibrosarcoma, situated between the strands of the cauda are reported, respectively, by McCosh[6] and Fränkel.[7] In the latter case, the involvement was unilateral, the mass confining itself to the fibers coming from the left side of the cord.

Cases in which the growth springs from the meninges are less common, and the variety of the tumors is small. Sarcomas are the most frequent and are generally of the small-celled variety. Endothelioma is met with less frequently than sarcoma, but the symptoms produced are quite similar. Starr[8] reports a case of this variety in which McCosh removed the spines and arches of the second, third and fourth lumbar vertebræ. The endothelioma had involved both hard and soft tissues, the spines and arches being eroded. Another case, which compressed the cauda equina, is reported by Troitzky.[9] Among other tumors which may be, though rarely, encountered in the meninges, are fibromas, lipomas and secondary carcinoma.

The greater number of tumors of this region are extradural in origin. Typical symptoms are produced by noted that in lesions of the latter, the "symptoms develop more rapidly; the various sensory disturbances may not be alike; pain and temperature sensations are more frequently seriously affected than tactile sense. Severe pain is absent, provided the conus lesion does not involve the cauda fibers. Disease of the conus is more likely to cause decubitus than caudal disease. The most important symptom of caudal disease is pain. A conus lesion may be associated with pain, provided the cauda meninges are also involved. The absence of pain is indicative of conus lesion."

V. Bechterew[18] makes the point that the principal differentiating feature between lesions of the cauda and of the conus medullaris consists in the fact that conus lesions cause an anesthesia limited to the anoperineal region, and that the sciatic field, so commonly affected in cauda lesions, does not participate. The differential diagnosis of the two conditions is important, since disease of the cauda equina is often amenable to surgical treatment.

This consideration of the symptoms of disease of the cauda equina and its differentiation from lesions of the conus indicates clearly the basis on which a diagnosis of disease of the cauda equina was made by Dr. Sippy, after which the case was transferred to the surgical service of Dr. Bevan for operation.

In reference to the height of the lesion, if no local signs indicating involvement of the spine are present, as in this case, to aid in locating the lesion, it is proper to assume that the upper limit of the lesion is just above the exit of the highest nerve disturbed. A reference to Figure 2 will show *that the highest nerve disturbed* in this case is the fourth lumbar.

Operation.—July 16, an incision was made extending several inches above and below the fourth lumbar vertebra. A spindle-shaped mass, three inches long and two inches wide, was found to the right of the spines, situated outside the laminæ. A part of this was excised, two laminæ removed, and the membranes of the cord were found to be made up of the same solid tissue. The incision was closed without drainage. Cover glass preparations of the tumor stained for bacteria, as well as inoculation of tubes of blood serum and glycerin agar, were negative.

The part of the tumor mass removed weighs 30 grams and measures 6 cm. in length, this axis corresponding to the axis of the spinal cord; 4 cm. in width, this corresponding to the lateral diameter of the body, and 2.5 cm. in depth, this corresponding to the antero-posterior diameter of the body. The shape is irregularly triangular, the base and apex of which are formed, respectively, by the upper and lower poles of the tumor. The color, a whitish gray as a whole, is modified somewhat in two areas, one (Fig. 3, b) on the posterior and left lateral aspect, where a dark-red color marks a portion incorporating the deep muscle fibers of the back. The second variation is noted at the base of the triangle on the right side, where a nodule (Fig. 3, a) 1.5 cm. in diameter presents a creamy white appearance. The relation of the removed mass to the neighboring structures is as follows: The anterior surface was in direct contact with the laminæ of the vertebral column; the posterior surface incorporated in the deep musculature and fascia of the back; the lateral parts of the removed piece were in contact with the rest of the tumor mass, which was not removed. The consistency of the tumor removed is firm, rebounding when dropped on the table. On cut section the knife meets with firm resistance, and the same general color noted above persists, but in addition are many small yellow areas, varying in size from a pin head to a small bean. The largest of these yellow areas is seen in the nodule described above.

Many sections were taken from different parts of the tumor, and the predominating arrangement is as follows (Figs. 4 and 5): The capsule is thick and composed of large wavy strands of fibers arranged in lamellæ. The nuclei are elongated, spindle-shaped and deeply stained (hematoxylin and eosin). The intercellular substance is homogeneous and pink. Young blood vessels are present in great numbers and many contain red-blood corpuscles. Blood spaces without walls occur between the lamellæ, the red-blood corpuscles coming in direct contact with the fibers of the capsule. Clumps of small,

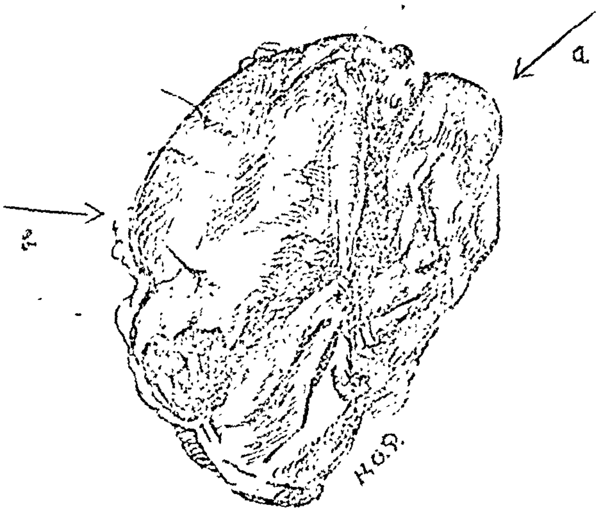

Fig. 3.—The mass removed. a and b, sites from which sections were made.

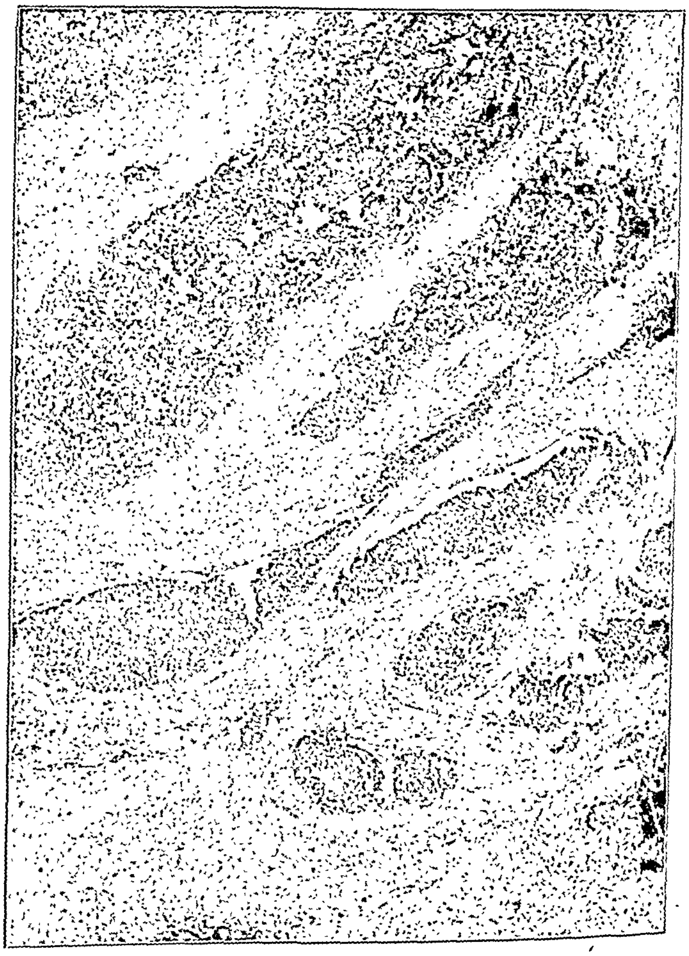

Fig. 4.—Section taken from part of tumor, indicated by arrow b in Figure 3. (Low power photomicrograph.)

---

[18] Rev. de Psych. et de Neurol., No. 9, 1899.

round cells are scattered diffusely throughout the capsule. Extending from the capsule are trabeculæ, projecting into the substance of the tissue, dividing the parenchyma into innumerable alveolar areas. The structure of these trabeculæ resembles that of the capsule, except that the smaller divisions show degenerative changes, due probably to pressure caused by growth of the parenchymatous tissue. The nuclei in the trabeculæ are less deeply stained and the intercellular tissue of a lighter pink color. The blood vessels in these trabeculæ are interesting. Some of the vessel walls are composed of a single layer of endothelial cells, which are in direct contact with the fibrous structure of the trabeculæ; these vessels are large and contain red corpuscles. Other vessels are present which have exceedingly thick walls, very narrow channels, and contain but few corpuscles. In many of the blood vessels are large heavily stained cells, similar to those found in the acini of the tumor, and which are to be described later.

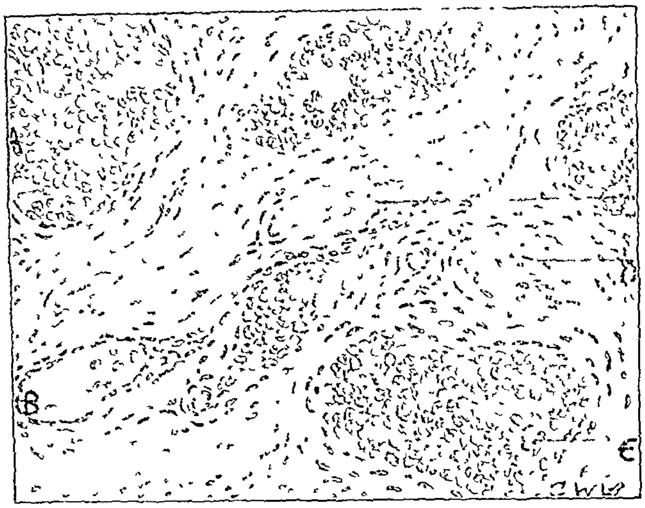

Fig 5—(High power drawing) A, Tumor cells; B, blood vessel containing tumor cells; C, extravasation of blood into stroma; D, stroma; E, young blood vessel among tumor cells.

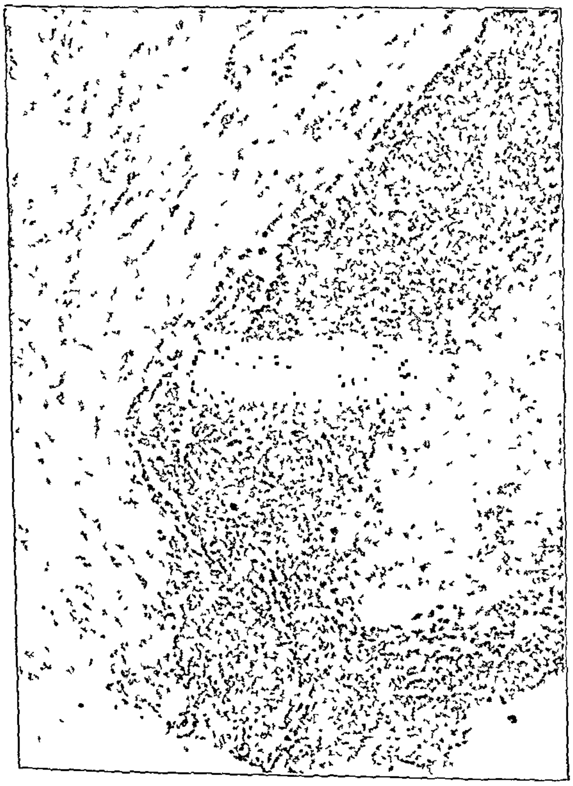

Fig 6—Meningeal involvement—dura invaded by tumor cells. (Photomicrograph)

The parenchyma is arranged in round, oval or irregular-shaped areas, ranging in size from small microscopic divisions, to the size of a pea. These dark-staining masses with thickly beset cells, present a marked contrast with the paler enveloping trabeculæ. The cells are large, round or epithelioid in shape and closely arranged. Their protoplasm in general is translucent, containing many irregularly arranged chromatic granules. Young blood vessels containing red-blood corpuscles are seen in the parenchyma; the walls of these are made up of tumor cells. Areas of degeneration, varying in size from small microscopic areas to .5 cm., are noted in many of the alveoli, especially the larger ones. These areas are of a hyaline-like character, stain pink, and present a homogeneous ground substance in which are imbedded transparent degenerated cells. They correspond to the areas described in the gross section as yellow-colored spots. The faint reticulum contains much blood.

A portion of the dura excised from where the membranes were involved in the tumor, showed, on microscopic examination, invasion by the same tumor cells described in the foregoing (Fig. 6).

The age of the patient, the rapid growth of the neoplasm, its histologic structure and the progressive course of the disease since the operation, are all in conformity with the diagnosis of sarcoma.

Results.—Three months after the operation the patient was found greatly debilitated, and presented an exaggeration of previous symptoms. Control of the bladder was entirely lost and involuntary bowel movements frequent, especially when the patient was asleep. He was unable to walk or even to support himself on his lower extremities. The pains in the limbs and back continued as before the operation, and emaciation was marked.

I am indebted to Dr. E. R. LeCount for valuable suggestions and criticisms during the preparation of this work, and to Drs. B. W. Sippy and A. D. Bevan for the clinical record of the case reported.[19]

RECENT ADVANCES IN ACTINOTHERAPY.

WILLIAM S. GOTTHEIL, M.D.
Dermatologist to the City Hospital and to Lebanon and Beth-Israel Hospitals.
NEW YORK CITY.

Young as is the treatment of disease by the various forms of radiant energy, there is already confusion in its terminology, and it will not be out of place to begin this review with the statement that the term "actinotherapy" is now the accepted designation for the method that employs the violet and ultraviolet spectral rays. The *x*-ray treatment is known as "radiotherapy," while "phototherapy" is employed for all kinds of light treatment collectively. There is need for insistence on exactitude in the employment of these terms, and even some of those who especially occupy themselves with phototherapeutics are open to criticism in this regard. Thus Freund entitles the authoritative work that he has just published "*Grundriss der Gesammten Radiotherapie,*" including therein not only the Röntgen treatment. but also that by high-frequency currents, Becquerel rays, visible and ultraviolet light rays, and even heat rays. The latter two agents he groups under the subheading of phototherapy. If the masters are not clear in their terminology the pupils will certainly go astray.

---

[19] I would mention, in addition to the authorities already cited, the following: Thorburn, W.; Med. Chronicle, 1889, x, 177-180; Fisher, W. W.: Tr. Prov. M. and S. Assn, Lond, 1841, 2, x, 203; Oliver, J.: Brain, Lond, 1886 7, ix, 550 552.

The scope of this retrospect is therefore restricted to the consideration of the progress that has recently been made in the therapeutic use of the ether vibrations that are appreciable to the unaided eye, together with the ultraviolet and chemically demonstrable ones that lie just beyond them. It practically includes only treatment with concentrated sunlight and with the various forms of the electric arc. It does not include treatment with the ordinary incandescent bulbs; and as there is a very prevalent misconception on that subject, it may not be out of place to refer to it here. The sun and the voltaic arc are the only efficient sources of actinotherapeutic energy that we possess. The incandescent bulb light has extremely little actinic power and penetration; nor can any practicable increase in its candle power or number give us a light that is comparable with even a very small arc in these qualities. The so-called light baths that are equipped with incandescents are practically sweat baths, and nothing more. The assertion that any actinic effect is gotten from them is entirely unsubstantiated, and I shall not consider them in this review.

A number of forms of apparatus, announced as improvements on the original Finsen type, have been introduced during the last year or two. Their aim throughout has been the very desirable one of simplifying and cheapening the apparatus, for it can not be denied that the Danish machine is complicated and troublesome to run, as well as expensive to install and use. I have had an opportunity to see and examine a number of the newer models, including the dermo-lamp, the Lortet-Genoud and the London lamp, and with the others I am familiar from the drawings and descriptions. They all run on small amperages and can be used on the ordinary incandescent wiring, and insofar possess very apparent practical advantages. They all give a superficial reaction; but they can not be expected to have any penetrative power. No attempt has been made to prove that their feeble light penetrates even the epidermis. In experiments recorded last year,[1] I proved that light of sufficient intensity from an arc could be made to penetrate not only the skin, but all the internal organs, and even the skin of the back after traversing the entire thickness of the body and then to influence a photographic plate. I used, however, a 50-ampere arc, giving a 20,000 to 30,000 candlepower light. Power is required for penetration; and without penetration, we can not expect to affect even the deeper layers of the skin, much less the internal organs.

This is a legitimate criticism of the new machines running on from 2 to 10 amperes of current. We can not hope to treat the deeper dermatoses with them, and it is entirely useless to attempt to affect a tubercular or carcinomatous focus in one of the internal organs. It is precisely in these fields that the future of the method lies. The few superficial dermatoses that are amenable to the action of the low-power instruments can well be treated by other means. In the latest publication from his institute,[2] Finsen is especially emphatic on this point. Leredde[3] agrees with him, and says justly that the intensity of surface reaction is no measure of the deep effect. The Lortet-Genoud apparatus gives a bulla in twenty minutes, but the light does not penetrate the tissues. It takes fifteen minutes for it to penetrate a rabbit's ear and affect a sensitive plate. Thinner living animal tissue than that it would be hard to find. With the powerful apparatus that I employ, a muscular human forearm can be penetrated in about the same time, and the chest or abdomen in two or three times the length of time required by the Lortet-Genoud apparatus to penetrate the rabbit's ear. The conclusions that I came to were that light from a source of sufficient actinic power and in sufficient concentration can be made to penetrate the entire thickness of the human body, including both layers of the skin, and that all the internal organs are accessible to its influence; and also that, since no organ or tissue can be more than half the thickness of the body from a cutaneous surface, and most of the internal organs are much less than that distance, the time required for efficient actinic penetration to any depth would be only a fraction of that required in the experiments; and conversely, if the time employed were equal, the chemotaxic effect would be much greater.

Both Finsen and Leredde conclude, and I thoroughly agree with them, that we must abandon the newer weak forms of apparatus, and return to those that concentrate large amounts of light. Of these only two are available. The original Copenhagen model is now purchasable in Europe, but it is hardly suited for any but institution use. It is extremely bulky, must be suspended from the ceiling, and requires an entire room. It is true that four patients can be treated at once; but as almost all the light comes from the crater of the arc, and since that crater is continually changing its position, it is evident that each of the four tubes radiating from the light will receive on the average only one-fourth of the light. This is the chief reason for the daily sessions of an hour or more for long periods of time that are required at the institute.

The instrument that I employ, while by no means small, is movable on castors and is suitable for the office. The full actinic force of the arc is directed on the area to be treated, and the only limit to the concentration of the circle of light is the efficiency of the cooling device in cutting out the heat rays.

Some legitimate objections to the earlier forms of the apparatus have lately been removed. The use of ordinary glass in the condensers and waterbath, which impedes the passage of the ultraviolet rays, has been abandoned; a Jena glass that is almost as transparent as rock crystal to them is now employed. Such, at least, is the assertion of the manufacturers. I can only state from careful comparative spectroscopic tests that it permits very much more of the ultraviolet to pass through than does the ordinary material. I also use a new carbon containing a large amount of iron and manganese in the place of the ordinary electrode. It gives a markedly violet flame that is entirely different from the usual light.

Of other improvements in the apparatus there have been but few. Broca[4] has improved the compressor which is necessarily employed with the low amperage lamps to get any penetration at all. I have not found it necessary to use anything of the kind. De Beurmann[5] applies a 1/1000 adrenalin solution to the part to expel the blood. He claims that it can be kept anemic for an hour in this way. Piffard[6] has lately demonstrated an improvement on this method, using cataphoresis to drive the adrenalin into the tissues. The iron electrodes that Bang announced last year have appeared. They seem to work well for short periods of time with the smaller machines.

[5] Ibid., July, 1902.

In the present state of our knowledge of the subject, I am prepared to say that it is quite useless to attempt actinotherapeutic work with anything less than 20 amperes and 55 volts; and that double that force is desirable if the internal organs are to be treated.

Some attention has recently been paid to the employment of sunlight in the place of the arc. Its applicability is limited, of course, since it can only be used during certain hours on bright days; but the absence of cost and the simplicity of the apparatus required are in its favor and I think will be extensively employed. The conditions are somewhat different from those with the arc. In the latter case we are dealing with rays diverging from a point, and it is desirable to approach the collecting lens as closely as possible to the source of light; and expense limits the size of the lenses in the machine. In sunlight we have practically parallel rays, and the amount of light collected is limited only by the size of the lens. Some ultraviolet light passes through all glass, and it is therefore possible to make the sunlight collecting lens of ordinary glass so large as to compensate for its deficient permeability, and make it equal in actinic power to a smaller rock crystal or glass lens. These considerations have led Finsen to employ ordinary glass and not rock crystal in his sunlight apparatus. The arc contains more violet and ultraviolet rays than does sunlight, on account of the atmospheric absorption; and the electric light can be used on any day and at any time of the day or night.

It would lead me too far to go into the consideration of all the various methods and apparatuses now employed, and I shall, therefore, proceed at once to a very brief consideration of the theory of actinotherapeutic action. The spectral rays that we employ are certainly bactericide. Velyaminoff[7] has experimented very extensively with the most varied pathogenic and non-pathogenic organisms, and states that the micro-organisms are directly and rapidly destroyed by the light; and Nagelschmidt[8] agrees with him. Sack,[9] on the other hand, is more inclined to attribute the results obtained to the photochemical and inflammatory effect. There is also an undoubted effect on the vasomotor nerves. Capillary dilatation, as Bie[10] has shown, is an invariable effect; and this is not a temporary matter, but persists for a long time, even for months, after the other effects of actinic action have passed. In fact, the latest investigations would tend to show that the rays cause a distinct endovasculitis after a time, and that, while slight action may cause vascular dilatation, the ultimate result is an inflammation of low grade with consequent permanent atrophy of the vascular tissues. We must conclude that the action of the light rays is a complicated one. It is, in part, directly bactericide and in part photochemical on the vasomotor nerves and the vascular structures. In addition to these, there are remoter effects in the stimulation of the tissue oxidation processes and new connective tissue formation.

In one respect the light action differs markedly from that of the *x*-ray, and that is a very important one from a practical point of view. The reactive tissue changes that it occasions are always moderate and controllable; and they appear promptly. There is never any delayed, excessive or uncontrollable effect. The condition of the hands of many of the Röntgen operators, and their insistance on their patients signing a release before beginning treatment, is sufficient evidence of the reality of the danger. A very considerable experience, now extending over several years, leads me to be positive on this point, and this with the most powerful currents available. The reaction can be pushed to vesiculation in a single session, if desired, and redness and swelling always occur. But all these phenomena disappear in a few hours or a day or two, and require, at the utmost, the application of a dusting powder. There are never any remote effects. Actinotherapy is perfectly safe.

Turning now to that portion of the subject that interests us most—the results obtained from the method—we are confronted with the facts that it has so far been employed by dermatologists almost exclusively, and that many of these used only the smaller and inefficient apparatuses to which attention has already been drawn. The report material is large, but not all of it is valuable. In lupus vulgaris, tuberculosis verrucosa cutis, tubercular ulcer, postmortem tubercle, etc., it is firmly established, not only as the most eligible, effective and innocuous treatment, but even as a test. Lesions that do not react and improve under it are not tubercular. Finsen's cases now number about 1,000, and almost all of them have been cured. His conclusions have been confirmed by many recent investigators, of whom I shall mention only a few. Klabowsky[11] reports 37 cases, including many old and intractable ones, that all did well. Gaston, Baudouin and Chatin[4] report 78 cases, one-third of them being completely and permanently cured; most of the others came irregularly or disappeared. There are similar experiences from a long list of investigators, among whom I shall merely mention Petersen,[12] von Ziemssen,[13] Velyaminoff,[14] Schmidt,[15] Sack,[16] Danlos,[17] Jessner,[18] and Hopkins.[18]

I have treated a number of cases myself with most excellent results, but I have not as yet published anything about them. I have had sufficient personal experience, however, to entirely confirm the conclusions of the European investigators. The affections are cured with the smallest possible amount of tissue absorption; the cicatrix is often hardly apparent. This is a point of extreme importance, since the face is the part most often affected.

Lupus erythematosus is a new field for the actinotherapeutic method. An article will shortly appear embodying my own results. Out of four private cases I have had three cures, and the fourth one was very extensive and of many years' standing. The patient lived in a foreign country, and was only under treatment for a short time. Ravogli[19] has treated a case of nine years' standing, in which the nose and both cheeks were involved. Finsen's latest report includes 31 cases, with 11 complete recoveries; and 19 cases were still under treat-

ment at the time the account was written. Leredde and Pautrier had 23 cases; 3 were complete failures; 3 were improved; 6 had "segmentary cures" of the patches treated, and 11 were entirely cured. These authors have added some interesting details concerning their cases, which are worthy of note as emphasizing the intractability of the disease and enabling us to estimate the value of their results. They had had altogether not less than 802 galvanocaustic séances, 382 scarifications, 462 high-frequency current sessions, without the cure of a single patch. Many of the authors previously mentioned record good results in the disease; a recapitulation is unnecessary. My own opinion is that at least one-third and possibly one-half the cases of this obstinate affection are curable by actinotherapy.

I have treated several cases of alopecia areata, and have on the whole been satisfied with the results. I believe, however, that it is very evident that under that designation are included at least two distinct affections, one of which is circumscribed, limited to the scalp chiefly, and benign in that it tends ultimately to spontaneous recovery, while the other is progressive, affects the entire body, and is malignant in the sense that treatment seems to have but little effect on its course. All my cases were of the former variety, but I can testify to a surprisingly rapid return of the hair in the patches treated. In some cases there was a good growth of lanugo hair after half a dozen sessions. Whether these cases are parasitic or not, our knowledge of the effects of light on the tissues would lead us to expect results; and I regard these cases as especially suited for this method of treatment. A number of other investigators give favorable reports, among whom Sack,[20] Schmidt,[17] Hyde and Montgomery,[21] and Leredde[4] may be mentioned.

Actinotherapy has been lately employed in the various forms of birthmark, nevus telangiectasis, etc. We are practically helpless in these cases when they are at all extensive; and, as the face is often affected, any method that promises relief is welcome. The endovasculitis excited by the light finally leads to cicatricial contraction and obliteration of the redundant vessels. A number of the writers above mentioned report successful cases, but I have not yet had occasion to try it in a suitable one. The difficulty has been that all my cases have been infants or very young children, whom it has been impossible to keep quiet while the light has been applied. I have tried in two cases to put the child to sleep with the aid of the breast or the nursing bottle; but this is an expedient that can not be employed with the regularity and for the length of time that is required. I have, therefore, been compelled to advise the postponement of treatment until the children are older. There then would be no difficulty in applying it, and I should certainly recommend its trial in adults, more especially in extensive cases of port-wine mark and non-hypertrophic telangiectasis.

A year ago Leredde, Bie, Blacker and Sequiera, Sjögren, Helm, and others reported cures of various cases of carcinoma of the skin, epithelioma, rodent ulcer, and Paget's disease with the light. That the more recent literature of the subject is small is probably due to the fact that radiotherapy has been so extensively employed in this class of cases, and that many experimenters have been using the smaller low-amperage apparatuses, to the inefficiency of which I have already called attention. Leredde[4] and Velyaminoff[16] have employed the more powerful machines with results at least as good as those obtained from the *x*-ray. I have no results to report as yet. My cases have been either extensive ones in hospital practice, in which, for reasons already stated, the treatment could not be employed, or private ones in which the circumstances precluded the use of a method that takes time. Further and extensive experimentation is required. The treatment is rational, in view of what we know of the action of the light, but actual trial only can decide as to its efficacy.

I have had one case of sarcoma cutis under the treatment for some time. It is quite extensive, however, and only a small portion of the growth can be treated at a time. The results have been fairly good. Individual nodules and tumors show distinct retrogressive changes under the influence of the light. The method is only applicable, of course, to the cases showing a single or only a few tumors. The disseminated cases, in which large areas or the entire cutaneous surface is affected, can not be treated in this way.

Rosacea, especially when the stage of permanent vascularization has been reached, would seem to be a good field for the employment of actinotherapy for the same reasons as in nevus. Finsen reports 15 of these cases, with 4 cures, 5 marked improvements, 1 still under treatment, and the remaining 5 as having stopped treatment after a short time. Bang,[22] and a number of others, report good results. I have used it in a number of cases of acne rosacea, but found it too slow to employ alone. It was generally employed in connection with curetting and local applications. I shall endeavor to use it exclusively in the next bad case of acne pustulosa that I meet.

In the parasitic skin diseases, ringworm, favus, sycosis and pityriasis versicolor, Von Ziemssen[23] and Leredde[24] have done well with the method. The same authorities report good results in psoriasis and rhinophyma. I have not been able to do anything with it in psoriasis; and we possess other simple and effective means of treating the disease. A number of investigators have used the method in various eczematous affections, in burns and wounds, in tropical ulcer, etc., but neither their number nor their results warrant their inclusion in this report.

As regards the employment of actinotherapy for the internal organs, the only reports as yet are those of Freudenthal[25] and Williams.[26] The former has found that the light is a most important factor in combating the symptoms of hay fever, and a valuable adjuvant in the treatment of pulmonary tuberculosis. The author takes a very conservative position in the matter, as is entirely proper in view of the very limited amount of work that has as yet been done in this field.

I can only say that the method is a promising field for investigation. The bactericide and tissue stimulating action of light is proven, as is also the fact that it can be made to penetrate the body and reach the internal organs. Whether its properties can be successfully employed for the treatment of diseases of the internal organs must be left for future investigation to decide.

EXAMINATION OF THE BLOOD OF PNEUMONIA PATIENTS FOR PNEUMOCOCCI.[*]

FRANK C. KINSEY, A.M., M.D.
THREE RIVERS, MICH.

INTRODUCTION.

The considerations which led to the present investigation are briefly as follows: In looking over the work thus far accomplished with regard to the presence of the pneumococcus in the blood of pneumonia patients, one is struck by the contradictory results of the various investigators. When Prochaska[28] [33] finds the organism each time in a large number of cases, irrespective of the outcome of the disease, while men like Kühnau,[10] in Germany, and James and Tuttle,[18] in this country, find it rarely and only in fatal cases, the need of more research work on the subject is clearly to be seen. A second reason for this work which needs no emphasis is its value from a diagnostic point of view. If the pneumococcus can be recovered from the blood of pneumonias, as can the plasmodium of Laveran in malaria, diagnosis, prognosis and treatment are all affected.

The immediate objects of the present work were four; to determine:

1. Are pneumococci to be found in the blood at any time?
2. With what frequency may they be found in all cases?
3. What is the simplest method of finding them?
4. What is the prognostic value of positive results if such occur?

METHODS OF EXPERIMENTATION.

Instruments.—The instruments used for drawing blood in work of this description vary from the uncleanly wet cup of Petruschky[8] to the lancet of Schabad[10] and Kühnau.[16] Sittman[9] used a glass canula, which instrument was also employed by Prochaska.[28] White[21] used a syringe. In the present work a glass canula was employed, marked in cubic centimeters to register the amount of blood taken. One end was drawn to a tube which was ground to fit a platinum needle about six cm. long; the other end to accommodate a rubber bulb supplying sufficient suction to draw up the blood to any height desired. This instrument, purchased of Leitz, was found very satisfactory.

Media.—In the first few experiments litmus milk and blood serum were employed, as well as bouillon. Cole[31] of Johns Hopkins used sterile litmus milk and considered it superior to bouillon on account of the early acidification of the medium. Blood serum was also used by a few investigators; but the majority of workers employed bouillon, and hence this medium would be chosen for purposes of comparison and uniformity, if for no other reason. The ease with which it is prepared is another argument in its favor, and any lingering doubts as to its superiority would be dissipated by the warm recommendation of A. Fraenkel. For the above reasons, after the first few experiments, bouillon was used throughout the work. The bouillon was autoclaved at 110 C., and one of the flasks tested afterward for alkalinity, etc.

Technic.—Any attempt to cultivate bacteria from the blood is worse than useless unless done under the strictest aseptic precautions. The above observation may perhaps seem unnecessary in this connection, yet in reading over some of the work referred to above, one may well doubt its aseptic character on account of the technic employed. In many cases blood was taken from the finger—a point of technic which renders these results open to suspicion, to say the least. Kühnau[10] established this point experimentally in 18 persons by taking blood from the arm and finger of each case. Of the 18 fingers there were 12 contaminations, while not one occurred from the arm, making a convincing argument against the finger as a location for drawing blood.

The technic of the present work was as follows: The operator's hands were prepared by scrubbing for ten minutes with green soap and sterile water. They were then soaked in bichlorid, washed with alcohol, and finally with ether. In the meantime, an assistant scrubbed the field at the bend of the elbow, and put on a pad soaked with bichlorid. Then he exerted sufficient pressure on the upper arm to make the veins below stand out prominently. The operator then completed the preparation of the patient's arm by a rub with alcohol and afterward with ether. The sterilized instrument was then introduced into the most prominent vein in the sterile field. This was usually the median basilic or median cephalic, though the superficial median and radial veins were occasionally chosen on account of their prominence. The needle was introduced into the vein perpendicular to its surface with one firm push, causing a pain so inconsiderable as to require no local anesthetic. As soon as the vein was entered the blood appeared in the glass canula, being drawn up by the suction of the bulb. When a sufficient amount was obtained it was put into the flask of bouillon, gently agitated to mix the culture and allowed to grow in the incubator at 37 C.

REPORT OF BLOOD EXAMINATIONS.

The series below is made up of 50 cases, divided into two groups of 25 cases each. The basis of this division is simply a difference in the proportion of blood to bouillon.

Group 1.—In the first 25 cases, from 8 to 9 c.c. of blood were used to 50 c.c. of bouillon, making a dilution of about 1 to 6. Of these 25 cases, only 3 showed the pneumococcus, while the other 22 were negative.

The three positive cases were as follows:

Case 1.—A Greek at Wesley Hospital, aged 34. History of cold, followed by a chill, fever, and, subsequently, severe pain under the right nipple. Examination on admission showed dullness over entire right chest and moist râles. Abundant rusty sputum which contained pneumococci. Blood examination was made two days after admission, at which time the temperature was 102.6 F. (39.2 C.), pulse 80 and respiration 26. The blood was grown on bouillon in the incubator at 37 C. for two days when a brick-dust precipitate appeared at the bottom of the flask. Microscopic examination showed a small round or oval coccus with lance-shaped extremity occurring in pairs or singly, less often in small groups. Streaks on agar yielded the typical transparent, dewy growths of the pneumococcus, which stains showed in pure culture. On the afternoon of the day on which the blood was taken, the patient's temperature fell to normal. The patient was discharged cured one week later. In this case the pneumococci were found in the blood just before the crisis.

Case 2.—H. S., male, aged 18 years, entered Wesley Hospital with dullness on right side, pain, etc., and was diagnosed as pneumonia. The blood examination was made at 2 p. m. the following day with a temperature of 102.6 F. (39.2 C.), pulse 92 and respiration 24. Growth on bouillon and subcultures on agar showed pure colonies of the pneumococcus. Patient recovered.

Case 3.—Mrs. M., aged 52 years, admitted to hospital with a temperature of 106 F. (41 C.), pulse 152 and respiration

---

[*] Work done at Professor Zeit's laboratory, Northwestern University, Chicago.

SUMMARY OF GROUP 2 (25 CASES).

No.	Name, Age and Sex.	Hospital.	Clinical Condition.	Death or Recovery.	Result.	Remarks.
1	A. A., 24, Male.	Cook County .	Temp. 99.6, pulse 108, resp 20	Died.	Negative.	Blood taken during pseudo-crisis.
2	E. M M , 24, Male.	Cook County .	Temp. 102, pulse 96, resp 32	Recovered.	Positive. .	Many pneumococci.
3	W. E., 27, Male	Cook County .	Temp. 105, pulse 116, resp. 30.	Recovered.	Negative. .	
4	M. L., 33, Female	Charity	Temp. 102.5, pulse 120, resp 30. . . .	Died.	Positive .	Died following day.
5	O. P., 18, Male . .	Wesley.	Temp. 101.9, pulse 80, resp. 20.	Recovered.	Positive .	General infection.
6	D. P. S., 45, Male.	Cook County .	Temp. 103, ax., pulse 120, resp. 46 . .	Died. .	Positive .	Died following day.
7	J. C., 40, Male. . .	Cook County	Temp. 105, pulse 120, resp. 36.	Died. . . .	Positive. .	
8	W. M., 42, Male. .	Cook County .	Temp. 102, pulse 120, resp. 40.	Died. . . .	Positive .	
9	J. D., 52, Male. . .	Cook County .	Temp. 97.2, pulse 84, resp. 24.	[illegible]	[illegible]	Senile form.
10	H., 45, Male . . .	Wesley.	Temp. 101, pulse 84, resp. 38	[illegible]	[illegible]	Scanty growth.
11	E. D., 32, Male . .	Wesley.	Temp. 100, pulse 70, resp. 26	[illegible]	[illegible]	Pneumococcic otitis media.
12	H. J., 35, Female .	Wesley.	Temp. 102.4. pulse 107. resp. 26. . . .	[illegible]	[illegible]	General infection.
13	H. P., 30, Male . .	Cook County .	Temp. 103.2, pulse 130, resp. 80. . . .	[illegible]	[illegible]	Took oxygen during examination.
14	J. C., 24, Male. . .	Wesley.	Temp. 102 4, pulse 110, resp. 28. . . .	[illegible]	[illegible]	
15	N. C., 22. Female .	Wesley.	Temp. 102, pulse 128, resp. 34	[illegible]	[illegible]	First examination was negative, second positive.
16	G. A., 40 Male . .	Wesley.	Temp. 100, pulse 80 resp. 38	[illegible]	[illegible]	
17	P. R., 50, Male . .	Cook County .	Temp. 100.4, pulse 104, resp. 32 . . .	[illegible]	[illegible]	
18	G. W., 22, Male . .	Cook County .	Temp. 101.2, pulse 92, resp. 36	Recovered.	Positive .	
19	McV., 55, Male .	Cook County .	Temp. 100.6, pulse 104, resp. 32. . . .	[illegible]	[illegible]	Scanty growth.
20	W. H., 36, Male. .	Cook County .	Temp. 103, pulse 128, resp. 48.	[illegible]	[illegible]	Alcoholic.
21	H. E., 45, Male . .	Wesley.	Temp. 101, pulse 96, resp. 30	[illegible]	[illegible]	Following the crisis.
22	P. D., 40, Male . .	Mercy. . . .	Temp. 97.6, pulse 72, resp. 30	[illegible]	[illegible]	
23	H. C , 47. Male . .	Cook County .	Temp 99.8, pulse 112, resp. 36	[illegible]	[illegible]	Crisis previous day.
24	J. K., 27, Male . .	Cook County	Temp. 102.2, pulse 128, resp. 48	Died.	Negative. .	Alcoholic.
25	J. E., 47, Male . .	Cook County .	Temp. 103, pulse 150, resp. 40	Died. . .	Positive. .	

48. Dullness at first in the left lower lobe, which almost cleared up, when the left upper lobe became involved and friction sounds appeared. There was a constant delirium and a persistently high temperature of from 103 to 106.6 F. (38.5 to 41.5 C.). The blood examination was made with a temperature of 103 F., pulse 152, and respiration 36. On the third day the bouillon culture showed the pneumococcus in abundance. Confirmed by cultural controls. Two days later the patient died from heart failure with a temperature of 108 F.

Owing to lack of space, the negative cases will be omitted. The positive results constituted about 12 per cent. of this group of 25 cases. One of the positive cases died and 2 recovered. Of the negative cases, 11 died and 11 recovered.

Group 2.—Although the results obtained in this series of cases were found to agree with those of many investigators in the same field, still the question arose as to whether the proportion of blood to bouillon might not be so high as to inhibit the growth of the organism except in favorable cases. It is not necessary here to enter into a discussion of Ehrlich's side-chain theory, nor the action of the side-chains on the pneumococcus. But with this question in view it was suggested by Dr. Zeit that a second series of 25 cases be examined in exactly the same manner as the first, except that the proportion of blood to bouillon be lower, and results of the two groups be compared. Accordingly, in the second group, one part of blood was employed to fifteen or twenty parts of bouillon. A tabulation of the results of this second series is in the accompanying table, and the details are given in the following histories:

Case 1.—August A., of German nationality, aged 24. Trouble began with a chill and pain in the right side, followed by fever and rusty expectoration. Physical examination showed a consolidation of left lower lobe. Admitted to hospital with a temperature of 103 F., pulse 132 and respiration 30. Blood was taken for examination during what proved to be a pseudocrisis, with a temperature of 99.6 F., pulse 108 and respiration 20. The patient died. Examination of bouillon cultures and streaks on agar was negative.

Case 2.—Ernest McM., aged 24, a bicycle builder, was admitted to the hospital with a temperature of 100 F., pulse 136 and respiration 30. The temperature averaged 101 F. that day and 101.2 F. on the next, sometimes going to 102. Examined the following day with a temperature of 102, pulse 96 and respiration 32. The patient recovered. Examination of the bouillon cultures showed many pneumococci. Streaks on agar gave pure cultures without the capsule. Stains of the first generation by Welch's capsule stain showed remains of these structures, which disappeared entirely in the later generations.

Case 3.—William E., printer, aged 27, admitted to hospital with a temperature of 97, pulse 120 and respiration 30. The same evening his temperature rose to 102, pulse 120, respiration 30. The night before admission patient had a severe chill, followed by fever and cough, with pain in the right axilla. Rusty sputum. History of pneumonia one year before. Physical findings of lobar pneumonia. Examined, with temperature of 105, pulse 116, respiration 30. The patient recovered. Examination of bouillon cultures and agar streaks showed no pneumococci.

Case 4.—Mrs. L., aged 33, admitted to hospital with a temperature of 103.2, pulse 112 and respiration 32. History of chill with temperature. Physical examination showed consolidation of the right upper lobe, extending to the middle lobe. Blood was taken with temperature of 102.5, pulse 120 and respiration 30. Examination of the bouillon cultures showed many pneumococci, some encapsulated and others not. The organism was mostly in diplococcus arrangement with a few chains of four and five. In the agar were many nests of pneumococci with fewer capsules, while in the later generations no capsules appeared. The patient died following examination.

Case 5.—Oresti P., Italian, aged 18. Entered the hospital unconscious and vomited all night. Red blood count showed 4,352,000 and the white, 16,000. On admission the temperature was 101.4, pulse 90, respiration 40. The following day the temperature was 103.2, pulse 100. Shortly after admission the patient complained of pain in the back of the neck. Puncture was made by a hospital interne and growths of the cerebrospinal fluid showed pure cultures of the pneumococcus. This led to examination of the blood. At this time (4 days after admission) the temperature was 101.9, pulse 80, respiration 20. Direct smears on cover glasses showed no bacteria. Cultures of blood on bouillon were found to contain many pneumococci after the second day of growth. These were mostly without capsules, although a number still retained them. Nearly all were in the form of diplococci, with a few scattered chains. Growth on agar showed the characteristic dewy form. Microscopic examination showed pure cultures of the diplococcus without capsules. As the patient showed no physical signs of lung involvement, the blood was examined for the second time. Cultures in every way identical with the first resulted after two days' growth. The patient recovered.

Case 6.—D. P., aged 45, admitted to hospital with temperature 101.8, pulse 124, respiration 48. Rusty sputum; pain in the side, and physical signs of lobar pneumonia. Examined with temperature 103 ax., pulse 120, respiration 46. Patient died the following day. Numerous pneumococci were found in the bouillon culture, and streaks on agar yielded pure cultures of the diplococcus.

Case 7.—John C., laborer, aged 40. Admitted with temperature of 102, pulse 102, respiration 26. Vomiting, broncho-vesicular breathing, and bronchial breathing over small area over vertebral border of right scapula. Bronchophony. Moist râles at fourth rib. Consolidation over infraspinous fossa of scapula on the right side. Examined with temperature 105, pulse 120, respiration 36. The pneumococcus of Fraenkel was found in pure culture. Patient died.

Case 8.—William M., laborer, aged 42. Admitted to hospital with history of chill three days before, followed by fever. Pain in the right side, aggravated by coughing and deep breathing. Patient was an alcoholic who went on periodical drinking bouts. Physical examination showed crackling râles at end of inspiration; resonance diminished on posterior aspect of left side. Later bronchial breathing, bronchophony and dullness on right side. On admission, temperature 102.2, pulse 120, respiration 30, which was the average condition of the patient for three days. Patient examined on fourth day after admission, with temperature 102, pulse 120, respiration 40. He died two days later. Direct smears of the blood on cover glasses showed no bacteria present. Cultures of the blood grown in the usual manner yielded positive results.

Case 9.—James D., laborer, aged 52. Admitted to hospital with temperature of 97.2, pulse 84, respiration 24. Although this patient had all the physical signs of pneumonia, with consolidation of entire right lower lobe, he ran almost no temperature. Apparently of the senile variety. At the time of examination, five days after admission, the temperature, pulse and respiration were practically normal, as they had been all week. Direct smears of the blood on cover glasses were negative. Growths of the blood on bouillon for two days yielded a scanty pure culture of the pneumococcus, from which confirmatory generations were grown on agar. The patient slowly recovered.

Case 10.—Mr. H., laborer, aged 45. Admitted to hospital with a temperature of 102.6, pulse 84, respiration 38, and history of chill, dyspnea, pain in the right side and rusty sputum. Examination showed a small area of consolidation on the right side. Leucocytes 11,400. Examined three days after admission, with temperature 101, pulse 84, respiration 38. On the following day pneumococci were found in the bouillon in pure culture.

Case 11.—Eduard D., aged 32, foreigner. On admission, temperature 104, pulse 90, respiration 32. Physical signs of consolidation. Rusty sputum showing abundant pneumococci. Had an otitis media suppurativa, with discharge from both ears, smears from which showed pneumococci. Streaks of this pus on Loeffler's blood serum yielded pure cultures of the micrococcus pneumoniæ. Culture of the blood was made on the fourth day after admission, with a temperature of 100, pulse 70, respiration 26. Examination the following day showed the pneumococcus present in pure culture. Patient recovered partially and then had a relapse. At this time his blood was examined a second time with results identical with those recorded above.

Case 12.—Mrs. Hulda J., aged 35. Her case was not examined primarily for this series, but has been put in because of the later developments. She had what was thought to be an irregular typhoid or paratyphoid running some temperature for several weeks. The Widal could not be obtained in spite of repeated trials. No plasmodia could be found. The temperature continued irregular up to the time of examination, on which date the temperature was 102.4, pulse 107, respiration 26. No pneumococcemia had been suspected, but blood cultures were made as an experiment. On the following day cultures appeared which were so characteristic of the pneumococcus that examination was made microscopically at once. A few encapsulated pneumococci were found in each field. Many tests were made to rule out accidents. Streaks on agar showed many diplococci under the microscope. In neither medium was any other organism found. On the following day the feces were examined. Among the ordinary bacteria present were large numbers of encapsulated pneumococci; rarely in chains of three or four; nearly always in diplococcus arrangement.

Case 13.—Harry P., aged 30. Admitted to hospital with temperature of 102, pulse 136, respiration 32. History of chill six days before entrance, pain in the side, anorexia, headache, etc. Uses alcohol moderately, smokes to excess. Physical signs of lobar pneumonia of right chest. Temperature continued high until day of examination, three days after admission, on which date temperature was 103.2, pulse 130, respiration 80 (patient was taking oxygen). Bouillon remained sterile. Streaks on agar yielded no growth.

Case 14.—Joe C., aged 24, entered hospital with temperature of 102, pulse 138, respiration 30. Examined two days later, with temperature 102.4, pulse 110, respiration 28. History of pain in right side, increased by coughing. Chills. Constant cough. Pneumococci in the sputum and physical signs of pneumonia. Cultures of the blood on bouillon yielded the pneumococcus after two days' growth. Confirmed by pure cultures on agar.

Case 15.—Miss Nellie C., aged 22. Admitted to hospital with temperature of 103.2, pulse 120, respiration 42. History of chill followed by pain in the side. Many pneumococci in the sputum, and physical signs of pneumonia. Blood examination was made two days later, with temperature of 102, pulse 128, respiration 34. Cultures remained sterile. Four days after examination, she developed a pneumococcic arthritis, her temperature remaining high. A second examination of the blood was then made. This time many pneumococci were found in pure culture. Streaks on agar confirmed results of the bouillon. The patient slowly recovered.

Case 16.—George A., Greek, laborer, aged 40. Contracted bronchitis after sleeping in a tent. Eight days later had a severe chill. Entered hospital with a temperature of 100.4, pulse 76, respiration 20. Examination showed physical signs of pneumonia. Blood culture was made four days later, with a temperature of 100, pulse 80, respiration 38. Examination was positive.

Case 17.—Pat R., laborer, aged 50. Admitted to hospital with temperature of 101.4, pulse 104, respiration 40. Physical signs of lobar pneumonia. Many pneumococci in the sputum. On examination, the temperature was 100.4, pulse 104, respiration 32. Culture media remained absolutely sterile.

Case 18.—Gus W., waiter, aged 22. Admitted to hospital with temperature of 100, pulse 108, respiration 28. History of chill three days before, followed by pain over the entire body; cough which grew worse, and rusty sputum. An alcoholic. Physical signs of lobar pneumonia. Examined five days after admission, with temperature of 101.2, pulse 92, respiration 36. Cultures showed a few pneumococci in each field. Agar streaks were confirmatory.

Case 19.—Simon McV., laborer, aged 55. Admitted to hospital with temperature of 100, pulse 88, respiration 28. History of chill, followed by pain in the right side. Physical signs of consolidation of the right upper lobe. On examination the following day, temperature was 100.6, pulse 104, respiration 32. Blood showed a few pneumococci after two days' growth. The patient recovered.

Case 20.—William H., laborer, aged 56. On admission, temperature was 104, pulse 132, respiration 30. History of chills, fever, pain in the side, anorexia, rusty sputum. Drank whisky to excess. Physical signs of consolidation of the left lower lobe. Patient was examined two days after admission with a temperature of 103, pulse 128, respiration 48. Cultures showed a few pneumococci present in each field. The patient died.

Case 21.—Herman E., aged 45. Admitted to hospital with temperature of 101.8, pulse 110, respiration 40. History of chill, pain in the right side, and cough. Physical signs of a lobar pneumonia. Drinks alcohol regularly but moderately. Examined five days after admission, with temperature 101, pulse 96, respiration 30. Culture was tested two days later and found to contain a few pneumococci. Agar streaks were positive. The patient recovered.

Case 22.—Patrick D., a driver, aged 40. Admitted to hospital with temperature of 100.4, pulse 94, respiration 26. Physical signs of consolidation of left lower lobe. Blood was taken for examination following crisis, with a temperature of 97.6, pulse 72, respiration 30. Examination of the culture two days later showed many pneumococci. Patient recovered.

Case 23.—Harry Van C., stableman, aged 47. Admitted to hospital with temperature of 101.2, pulse 120, respiration 50. History of chill, cough and pain in the right side. Had physical signs of a right lobar pneumonia. The patient was examined the third day after admission, at which time his temperature was 99.8, pulse 112, respiration 36. Cultures of the blood on agar and bouillon remained sterile. The patient recovered.

Case 24.—John K., colored, aged 27. Admitted to hospital with a temperature of 101.6, pulse 136, respiration 36. History of chill, shortness of breath, etc. Physical signs of right lower lobe pneumonia. The temperature came down nearly to normal and then went up again. Blood was taken during this relapse, with the temperature at 102.2, pulse 128, respiration 48. The cultures on bouillon and agar remained absolutely sterile. The patient died.

Case 25.—John E., aged 47, was admitted to hospital with temperature of 103, pulse 150, respiration 40. Presented physical signs of a pneumonia of the left lower lobe. Cultures were made on the day of admission. Examination the following day showed many pneumococci. Agar streaks were confirmatory. The patient died.

RESULTS.

The present investigation started with four questions:

1. Can pneumococci be found in the blood at any time? This must be answered in the affirmative, because of the results secured in our investigations and in those of others.

2. With what frequency may they be found in all cases? In the first series there were 3 positives in 25 patients, or 12 per cent. of the entire number. In the second series, with a method more favorable to the growth of the organism, there were 19 cases, or 76 per cent., with positive results. Of the 6 negative cases, 2 might be considered unfavorable for the recovery of the *pneumococcus* from the blood on account of the condition of the patient at the time of the examination. Case 1 was negative, with a temperature of 99.6 during a pseudo-crisis, and Case 23 was negative, with a temperature of 99.8, after a crisis the previous day. It is possible that, had a blood examination been made while the temperature was high, the pneumococcus might have been isolated. On the other hand, Cases 9 and 22 were positive with a subnormal temperature, showing that a high fever is not absolutely essential in pneumococcemia. In the other 4 negative cases we can offer no explanation. Nevertheless, from the results of this investigation, we are inclined to agree with A. Fraenkel[30] and Prochaska,[25] that the pneumococcus may be found in the blood of every pneumonia patient, and, with Silvestrini and Sertoli,[23] attribute negative results to unfavorable conditions for growth or failure in technic.

3. What is the simplest method of finding them? The technic has been described above. We believe the best results are obtained by taking large quantities of blood (from three to six c.c.) with a dilution of over one to twelve of a liquid-culture medium, preferably bouillon.

4. What is the prognostic value of positive results? We believe that the mere finding of the pneumococcus in the blood is of no prognostic importance whatever. Of the 19 positive cases in the second series, 69 per cent. recovered and 31 per cent. died, while of the negative cases, 33 per cent. recovered and 67 per cent. died. Hence, according to our series, no worse prognosis, at least, attaches to a positive than to a negative finding. So many of our cases, however, were associated with alcoholism that these prognostic percentages hardly represent the average. But in our cases when the organism was found in the blood of a patient who subsequently died, it was invariably present in large numbers, while, with two exceptions (Cases 2 and 15, both severe infections), few pneumococci were found in those positive cases which recovered. According to our results, then, the mere finding of the pneumococcus has a diagnostic, but not a prognostic bearing, while the finding of large numbers of pneumococci is of grave prognostic import.

I wish to thank the visiting physicians and the resident staff of the Cook County, Wesley, Mercy, St. Luke's and Charity hospitals for many kindnesses, and Dr F. Robert Zeit of Northwestern University for many valuable suggestions as well as excellent advice throughout the work.

BIBLIOGRAPHY.

The following résumé comprises practically all that has been done up to the present time on the organism in the living blood:

1. Telamon (Le Progrès Medical, 1883, No. 51) examined the blood in 25 cases of pneumonia. He found the pneumococcus twice, both times but a few hours before death. Tests of the same cases the day previous were negative.

2. Friedlander (Fortsch. der Medicin, 1884. ii, p. 333), examining the blood of 6 cases of acute pneumonia, found the pneumococcus but once.

3. Netter (Arch. Gen. de Med., 1887) reported one positive case which was complicated with meningitis and peritonitis.

4. Befanti (Riforma Medica, 1890, No. 37. Referat Baumgarten's Jahresbericht, 1890, p. 63) reported that he found the diplococcus of pneumonia present in the blood of many (does not state the number) examined by him during life.

5. Boulay (Des affections à pneumoc. indep. de la pneumonie franche, Paris, 1891. Ref. Kraus. Zeitschr. f. Heilk., 1896, p. 117) had a series of 4 cases with 2 deaths, from the latter of which he reported positive results. The 2 recoveries showed no pneumococci.

6. Goldschneider (Deut. med. Wochensch., 1892, No. 14) recorded 2 positive cases with one death in a complicated case.

7. Canon (Deutsche medicinische Woch., 1893, p. 1038) in an investigation covering many varieties of sepsis, reported one case of pneumococcemia with jaundice in which blood cultures on agar showed from 10 to 15 colonies of pneumococci.

8. Petruschky (Zeit. für Hyg. und Infct., 1894, vol. xvii, p. 59) in a series of cases had 4 pneumonias, one complicated with erysipelas. Examination of the blood was in all cases negative.

9. Sittman (Deut. Archiv f. klin. Med., 1894, p. 327), had 16 cases of pneumonia with positive results in 6 cases, 5 of which were complicated with lesions in other organs, 4 of the positive cases were fatal, while of the 10 negative cases 9 recovered and one died. The positive results were obtained from one to seventeen days before death in the fatal cases.

10. Schabad (Centralbl. f. Bact., 1896, vol. xix, p. 991) in a case of pneumococcemia involving practically all the organs of the body, obtained positive results from agar growths of the blood. The first generation was encapsulated, the second not.

11. Kraus (Zeitschr. f. Heilk., 1896, vol. xvii, p. 117) in a series of 12 cases reported that the blood showed pneumococci in only one instance. This case was complicated with erysipelas. He had growths (contaminations) in all 12 of his cases.

12. Grawitz (Charité-Annalen., 1896, vol. xiv) reported one positive case with death.

13. Nicolaysen (Am. pnevmokokkens Lokalisationer udenfor Lunegen. Norsk Magazin for Laegevidenskaben, 1896, p. 374) reported a positive finding in a pneumococcemia 2 days before death.

14. Duflocq (Lecons sur les bactéries pathogènes, 1897, pp. 147-8. Ref. Beco. Revue de Médecine, 1899, p. 461) in 1896 reported one positive case with death.

15. Kohn (Deut. med. Woch., 1897, No. 9) had 32 cases, with positive results in 9, of which 7 died and 2 recovered. His positive results were obtained only a day or two before death in the fatal cases. Three times the results were negative and the patient died, but one of these deaths was due in an old man to his rising from bed too early and suffering a heart collapse.

16. Kühnau (Zeitscht. für Hyg. u. Infctsktn., 1897, vol. xxv, p. 492) examined the blood of 9 severe uncomplicated cases of pneumonia. In only two cases, both of which were fatal, did he find the diplococcus. Another fatal case was negative. The *Staphylococcus albus* was found 7 times and the *aureus* once.

17. Roemheld (Mün. med. Wochenschr., 1897, p. 603) had a pneumococcemia from which during life he drew blood on glycerin-agar with negative results.

18. James and Tuttle (Presbyterian Hospital, N. Y., Reports, 1898, vol. iii, p. 44) examined the blood in 12 cases of pneumonia. Two of these were fatal, the remaining ten recovered. No pneumococci were found in the entire series of inoculated tubes.

19. Holst (Norsk Mag. for Laegevid., 1898, No. 11) in a series of 23 pneumonias, obtained the pneumococcus in two and a staphylococcus in one. Of the 23 cases 4 died and the others recovered.

20. Preble (The Journal A. M. A., Aug. 19, 1899,) reported 4 observations, in 3 of which he obtained the pneumococcus in cultures and in all by direct smears of the blood. Two died and two recovered.

21. F. W. White (Jour. Experimental Med., 1899, p. 425) reported 19 cases, 3 of which were positive; all fatal. Seven of the negative cases were also fatal.

22. Sello (Zeitschr. f. klin. Med., 1899, p. 112) reported a series of 48 cases after Sittman's method. Of these 36 were negative with 27 recoveries and 9 deaths. Twelve cases were positive with 2 recoveries and 10 deaths.

23. Silvestrini and Sertoli (Riforma Medica, 1899, No. 16, Ref. Centralbl. f. innere Med., 1900, vol. xxi, p. 135) out of 16 cases reported the diplococcus present in 15; and in 24 investigations, present 22 times. The authors are inclined to attribute negative results to failure in technic.

24. Beco (Revue de Médecine, 1899, p. 461) had 50 cases with 11 positive findings. Twenty-nine recovered, of which 2 were positive; and 21 died of which 12 were negative and 9 positive. One of Beco's cases showed the Friedländer pneumobacillus.

25. Prochaska (Centralbl. f. innere Med., 1900, No. 46) reported his first series of 10 cases, all of which were positive. He had 4 deaths and 6 recoveries after long periods. No other colonies were found. The cases were not selected.

26. Lenhartz (Man. of Clinical Microscopy. Ref. Burt, Amer. Med., April, 1902) in 1901 reported 20.7 per cent. of positive results in a continuous series of 30 pneumonias.

27. Lenhartz (Muench. med. Woch., 1901, No. 28) found the pneumococcus 3 times, streptococcus 8 times, staphylococcus pyogenes aureus 4 times and the albus once in 16 cases of pneumonia with endocarditis.

28. Prochaska (Deutsch. Archiv f. klin. Med., vol. lxx, p. 559) in 1901 reported 40 additional cases of fibrinous pneumonia, in all of which micro-organisms developed, and, in the great majority of cases, the pneumococcus. In two instances pneumococci were not found, but micrococci in chains, which Prochaska did not know whether to regard as irregular forms of pneumococci or as separate germs. Eight of the 40 cases died and the rest recovered In none of the cases was there contamination from the skin or from the air.

29. Landi and Cionini (Deut. med. Woch., 1901, p. 296. v. reported a series of 27 pneumonias in which investigation of the blood during life gave positive results.

30. A. Fraenkel (Deut. med. Woch., 1901, Nov. Ver.) in speaking of the pneumococcus, in the blood said, "I have myself very often obtained cultures in the blood. One finds them when he takes large quantities of the blood (5 to 10 c.c.) and a liquid medium like bouillon, in every case. They seem to multiply better in a liquid culture medium. In other words, since we no longer take 1 c.c. of blood for our experiments, but 6 to 8 c.c., we find the pneumococcus in the blood in every instance.

31. Cole (Johns Hopkins Hospital Bulletin, June, 1902) made cultures in 30 cases of pneumonia, all lobar except one, which was a pneumococcemia with arthritis and meningitis. Of these 30 cases 9 were positive, with death in every instance. Four of the negative patients died also.

32. Herrick (Amer. Jour. Med. Sci., July, 1902) reported a case of pneumococcus arthritis in which puncture of the median basilic and growth on agar was negative.

33. Prochaska (Deut. med. Woch., 1902, No. 21) reported his third series of cases. He had 4 pneumonias, in all of which pneumococcus was found. He had 3 recoveries and one death.

34. Baduel and Gargano (Gazzetta degli ospedali e delle cliniche, Jan. 4, 1903,) reported an epidemic of pneumonia involving 8 children in one house, many of whom had complications. The pneumococcus was found in the blood of all these cases. Method not stated.

35. Rosenow (Medicine, June, 1903) reported cultures from 83 cases, with positive results in 77.

THE USE OF SILVER FOIL TO PREVENT ADHESIONS IN BRAIN SURGERY.

M. L. HARRIS, M.D.
CHICAGO.

The formation of adhesions involving the cortex of the brain and its covering membranes is the rock on which the ultimate success of many otherwise brilliant and successful operations on the brain is wrecked. The harmful influence of posttraumatic and postoperative adhesions of the surface of the brain in the production of epilepsy is universally recognized, and many suggestions have been put to application by the surgeon to prevent this occurrence, but only too often do we find that after a brilliant localization of a brain tumor or other cortical lesion by the neurologist, and a faultless operation by the surgeon, the terrible fits after a momentary pause recur with all the old vigor and frequency. It is unfortunately true that operative treatment in the large majority of the cases of epilepsy due to distinct local lesions is a failure, owing to the formation or re-formation of adhesions. The adhesions which are the most harmful are those which take place between the dura and the brain. Concerning these, Schär[1] says: "One may be able to elevate a depressed bone, remove a cyst or a connective tissue scar, or a mass which is pressing on the brain, but on the other hand, it is useless to divide adhesions between the dura and pia, or pia and brain, because the same immediately after the operation inevitably re-form."

Fortunately not all surgeons entertain such a hopeless view of the subject, and many of them have devised plans for preventing the re-formation of the adhesions, which are frequently successful. When a bone flap is formed which can be replaced, it has been suggested that the dura be removed entirely over the affected area, or that a flap of dura be brought out and turned over on the outer surface of the bone flap when the latter is replaced, after the methods of Keen and Chipault. These methods, which have apparently been followed by success, permit the brain or its covering pia to lie in direct contact with the inner surface of the bone, to which adhesions are not so likely to form. As a firm dura, however, is the best means of preventing the formation of that very unpleasant complication of brain surgery, namely, hernia cerebri, it is very desirable to retain this membrane whenever possible. It has, therefore, been proposed to interpose certain substances between the dura and the brain, in the hope that thereby the formation of adhesions might be prevented.

Beach,[2] in 1890, first suggested the use of gold foil for this purpose, and two years later used it in a case of epilepsy in which convulsions had returned after an operation done two years previous. Improvement followed the use of the gold foil at the second operation. Following this, cases in which gold foil was used were reported by Estes,[3] Oliver,[4] Summers,[5] Wier and others. Oliver's case, one of epilepsy, had been operated on before and some bone removed. Convulsions recurred and a second operation was done, adhesions separated and a plate of gold foil interposed. The patient had no more convulsions up to the time of his death, which occurred suddenly at the end of four months. At the autopsy the gold plate was found in position, and had served its purpose in that it had prevented the formation of adhesions. Woolsey[6] reports a case in which he used gold foil. The case was one of traumatic epilepsy. and had been operated on previously, at which time a piece of thickened dura about two inches in diameter was removed. As no improvement had taken place at the end of ten days, the wound was reopened and "a piece of gold foil was inserted between the scalp and the brain. The gold foil was sterilized by heat, but unfortunately it came in paraffined paper, and some of the melted paraffin had adhered to its surface. There were probably some small tears made in separating the paraffin from the paper." The patient was in perfect health for several months, when his attacks recurred. Dr. Woolsey reopened the wound and found that the gold foil had not prevented adhesions of the scalp to the brain. The gold foil had broken up into particles and between them newly formed fibrous tissue had grown, forming a layer of considerable thickness, embedding the gold foil and forming firm adhesions between the scalp and the brain. Dr. Woolsey was unable to say whether this would have been the result had the gold foil been entirely intact. It was the thickest foil kept in stock by a large dental manufacturing establishment. Freeman[7] says: "I possess a specimen of foil (gold) which I placed in the trephine opening in the posterior fossa during the course of an operation for cerebellar tumor. The patient lived about three months, and during that time considerable new connective tissue had formed." No details of this case are given. He does not state the nature of the tumor, whether it was removed or not, where the new connective tissue was formed, nor where the foil was placed.

The use of thin rubber tissue as recommended by Abbe has been tried by a number of surgeons, and with apparent success by some. McCosh[8] says: "One patient on whom I operated thirty months ago carries without signs of irritation a piece of this tissue on the surface of his dura. That it may, however, act as a foreign body is shown in Case 13, and there is no proof that the so-called 'life' should be longer in its new home than it would be in the external world." The case mentioned was one in which a piece of rubber tissue had been inserted. The patient did well for about twenty months, when his convulsions recurred. Another operation was performed. "A scalp flap was lowered over the old trephine opening, which was found filled with dense connective tissue, to which the scalp was intimately adherent. A layer about one-sixteenth of an inch thick was dissected off. Under this was felt a mass of apparently cicatricial tissue, very hard except near the center, where there was a roundish nest consisting of soft, almost granulation-like tissue, in which were seen blackish particles, which were found to be scraps of rubber tissue amalgamated with the soft connective tissue into a mass the size of a small cherry. This was cut out by scissors."

The case was then treated by placing over the brain a piece of platinum foil about the thickness of a sheet of note paper. Primary union and at the end of eight weeks he had no return of attacks.

Dr. Abbe,[9] who performed the first operation on this case and introduced the rubber tissue, says that "he was not surprised that development of granulations about the rubber had ultimately broken it up and enveloped it. It simply showed nature's effort to expel it when suppuration had once started. No argument could be based on this case as to the behavior of tissue in non-suppurative cases."

In 1898, Freeman[10] recommended the lining membrane of an egg in place of the inorganic substances. He tried the membrane in two experiments on animals, but had not used it on the human subject. In 1900, Greer[11] used egg membrane in an operation on a lad who eleven years before had sustained a compound fracture of the skull and who had suffered from epilepsy since. The skull opening, which resulted from the fracture, was found filled with dense tissue. In separating this tissue some brain substance was removed. Two pieces of eggshell membrane were placed—one between the brain and the skull and the other outside the skull. The scalp was then replaced and primary union occurred. Four months after the operation the old scar broke open and left a small hole in the scalp, through which the eggshell membrane could be seen. This was pulled out in its entirety. It was still tough and showed no apparent change in its structure. The wound then closed. The subsequent history of the case is not given, so we are left in doubt whether any good was accomplished by the operation or not.

The question of closing defects in the bone by celluloid or thick gold or silver plates or by plastic operations, is not under discussion, but simply the question of the prevention of adhesions between the brain and its membranes or the bone.

The general principle of the introduction of some foreign substance has been tried in a sufficient number of cases, and with results, too, which seem to justify our belief in its efficacy.

The best material to be used and the details of technic, however, are questions still to be worked out. There are some points which appear to be well established. For instance, the traumatism incident to the operation should be as slight as possible. A bone flap which can be replaced is preferable, when possible, to the trephine opening with the bone left out. Before the introduction of any substance hemorrhage should be perfectly controlled and all blood clots removed. The substance should extend well beyond the edge of the area involved in the adhesions. There should be no openings or breaks in the substance. The material must be one which can be sterilized. The wound must heal in a perfectly aseptic manner. The question of material is not so well settled. Whether the organic substances, such as egg membrane, prepared ox peritoneum, etc., will prove of value remains to be determined. They have not been used often enough to relieve one of the theoretical doubt of their efficacy, as the case of Greer, mentioned above, is unsatisfactory. Thin rubber tissue has been used a number of times with good results. The author has a patient who has carried a good sized piece of rubber tissue in his skull for several months with an excellent result. One disadvantage of the rubber is its tendency to roll up after it has been inserted. It then not only fails to fulfill its purpose, but may be an actual cause of irritation. The author knows of one unreported case in which the rubber, which had to be removed some months after it was introduced, was found all rolled up. The rubber may also be disintegrated by granulations, as in McCosh's case.

The use of the thick, unyielding metal plates or the heavy foils, such as the No. 60 or thicker dental gold, the author believes as a rule undesirable. The heavy plates may become tilted and act as irritants or gradually work their way to the surface; or late suppuration may occur, necessitating their removal, as the author has known in one case. Of the materials thus far proposed, the author believes the thin foils are the best, and of these he prefers the silver foil. It is so thin and soft and smooth. It conforms to all irregularities of the surface on which it is laid. As many layers may be applied as may be necessary to secure a smooth, unbroken surface. It is not only tolerated very kindly by the tissues, but exerts a beneficial influence on granulating or healing surfaces. The foil may be placed directly in contact with the brain tissue, between the pia and dura, or wherever it may be necessary to accomplish the purpose desired.

The author has used the silver foil in a number of cases of brain surgery, and while no claim for anything new is made, he wishes to urge its more frequent use for the purpose indicated, and with greater care in reference to the technical details above mentioned.

The following case will illustrate the application of the principle:

George P., aged 12. When three years old he fell out of a chair and injured his head. He was taken to a hospital, where he remained two weeks. After returning home he was all right for about two years, when he developed epilepsy. The attacks were of the jacksonian type, beginning in the left arm. In addition there was partial paresis of certain muscles of the left arm, and to a very limited extent of the left leg. He entered my service at the Children's Hospital, June 22, 1900. Dr. H. T. Patrick saw the case with me, diagnosed a cortical lesion involving the left arm center, and advised operation. This was done July 10, 1900.

A large osteoplastic flap was turned down, uncovering the area indicated. A subdural calcareous mass was found about 3 cms. in diameter by 1½ cms. in thickness. It was firmly attached to the inner surface of the dura as well as to the brain tissue. A dural flap was turned down and freed from the mass. In removing the mass the cortical surface of the brain was unavoidably injured, and quite a depression remained in the brain tissue. After controlling the hemorrhage, the dura was replaced and sutured, as was also the osteoplastic flap. Primary union occurred and recovery was without incident. He left the hospital Aug. 5, 1900.

Notwithstanding the fact that active treatment with the bromides was pushed after the operation, relief from the attacks only lasted about two months. They then recurred and gradually increased in frequency and severity until in February, 1902; when he again entered the hospital he was having from five to eight fits a day. The left arm was quite weak and movements impaired.

The second operation was performed February 17, 1902. The same osteoplastic flap was turned down, and the dura opened. Firm adhesions were found between the dura and the brain tissue. These were carefully separated and hemorrhage controlled. Several layers of very thin silver foil were then placed over the brain tissue, extending some distance beyond the area involved in adhesions. The dura was then replaced and sutured, and the skull closed as before. Recovery from the operation was perfect, and he left the hospital March 23, 1902. The bromid treatment was continued as before. He has been under observation up to the present time, and although it has been a year and ten months since the last operation, he has not only not had a single fit, but has improved materially in his left arm as well as in his general condition. He attends school regularly and says that he feels perfectly well.

A METHOD OF DISPENSING WITH RUBBER GLOVES AND THE ADHESIVE RUBBER DAM.

A PRELIMINARY NOTE.

JOHN B. MURPHY, A.M., M.D.
Professor of Surgery Northwestern University Medical School; Attending Surgeon Mercy Hospital, Cook County Hospital.
CHICAGO.

The disadvantages, inconveniences and dangers of rubber gloves and dam, as well as their theoretical advantages, are well understood and will not be commented on here. For several months past I have been endeavoring to find a material that might be applied to the hands of the surgeon and skin of the patient which would practically seal these surfaces with an insoluble, impervious and practically imperceptible coating—a coating that would not allow the secretions of the skin to escape and will not admit secretions, blood or pus into the pores or crevices of the skin, at the same time one that will not interfere with the sense of touch or impair the pliability of the skin. I have ascertained that a 4, 6 or 8 per cent. solution of gutta-percha in benzine fulfills all of these requirements, while a similar solution in acetone also meets most of the requirements. In my clinical experience in the last four months I have found that the 4 per cent. solution of rubber in benzine is the most serviceable for the hands, as it wears better on the tips of the fingers under handling instruments, sponges and tissues than the acetone solution. For the abdomen the acetone solution has the advantage, as it dries in from three to four seconds after its application, while the benzine solution takes from two to three and a half minutes to dry to a firm coating. The acetone coating when dry is only slightly adhesive while the benzine coating is sticky.

The method of application to the hands and forearms is that of simple washing as with alcohol, care being taken to fill in around and beneath the nails. The hands must then be kept exposed to the air with the fingers separated until thoroughly dry. They may then be washed in alcohol, bichlorid or any of the antiseptic solutions without interfering with the coating or affecting the skin. It wears off on the tips of the fingers if the operations be many or prolonged, when another application may be made between operations; on the remaining portion of the hands one application is sufficient for a whole morning's work.

My routine method of hand preparation is as follows: First, five to seven minutes' washing with spirits of green soap (5 per cent.) and running hot water; second, three minutes' washing with alcohol; third, after thoroughly drying I pour on the rubber solution after the method above stated, allowing it to dry without rubbing, after the surface is thoroughly covered. The coating is so thin it can only be recognized by its glazed appearance. The coating will resist soap and water washing to cleanse the hands between operations. It is removed by washing in benzine.

The abdomen or surface preparation is five minutes' scrubbing with spirits of green soap (5 per cent.), then washing with ether, followed by alcohol. The surface is then swabbed over thoroughly with the acetone or benzine rubber solution.

The gutta-percha solution is prepared by dissolving pure gutta-percha chips in sterile benzine or acetone. This was accomplished first for me by the chemist, E. von Hermann. These solutions do not stand boiling as it impairs the adhesiveness and elasticity of the coating. The advantages of this method of avoiding the dangers of infection from the hands and skin of the patient are very evident. In addition to the bactericidal properties of the benzine it prevents perspiration beneath the coated surface, and also the rubbing off of epithelia from the hands and skin surface into the wound. It does not puncture like the rubber glove, and where it wears off on the finger tips there is no accumulated epithelium or secretion beneath. It is, moreover, impermeable and precludes the ingress of infective flora or blood to the operator's skin. After operating, the surface washes clean as readily as the surface of a rubber glove. At the end of the day's work, when the hands are washed in benzine to remove the coating, the skin is very soft and smooth. The surgeon's hands are thus protected from all of the deleterious effects of daily operating, which is in itself a safeguard against infection. Inoculation and bacteriologic tests are being made and will be reported in detail later. The simplicity and ease of application of this method, with its practical certainty of protection, should appeal to every operator.

SIMULTANEOUS EXTRA-UTERINE AND INTRA-UTERINE PREGNANCY.

REPORT OF A CASE.

CHARLES A. STILLWAGEN, M.D.
Gynecologist to East End Hospital.
PITTSBURG, PA.

Mrs. O., aged 38, was married Oct. 2, 1902, and had menstruated regularly every 24 days until April 20, 1903, which was the date of her last period. She suffered more or less pelvic pain from that time. She was removed to St. Francis Hospital July 14, 1903.

The following history was furnished me by that institution: Family history, negative. Personal history: She had always been delicate, and particularly so since an attack of pneumonia two years ago. Menstrual history was normal, the last period having occurred April 20, 1903. Present illness began about June 14 with obstinate constipation, and severe pain in abdomen centered over sigmoid region. Her physician gave morphia to relieve the pain. Later she had severe vomiting and was given fractional doses of calomel without effect. High enemas were administered with some effect. June 20, 1903, patient aborted two-months' fetus. The abdominal pain persisted, and was most marked in the lower right quadrant; abdominal muscles were rigid. She was admitted to the hospital July 14, suffering from almost continuous vomiting, constipation amounting to obstruction and severe abdominal and lumbar pain. She was thin and emaciated, and of a sallow complexion.

Examination of the heart was negative. There was impaired resonance at the apex of the right lung in front and over the left apex posteriorly; bronchovesicular breathing posteriorly on the left side, anteriorly on the right side and subcrepitant râles on the right side anteriorly. The abdomen was distended, tender on pressure, rigid, dull in the flanks and over the hypogastrium. No tumefaction could be outlined. An evacuation of the bowels was secured July 16, after which all symptoms were somewhat relieved, but the patient became dissatisfied and returned to her home July 20.

At her home a diagnosis of abdominal pregnancy was made by Dr. R. M. Sands, who sent her to the East End Hospital, for operation, where she was admitted August 6. Throughout her illness morphia had been administered only in sufficient quantities to relieve pain, but she had become more or less addicted to the drug. She was emaciated to the last degree. A large hard mass could be felt in the right iliac region which protruded so that it could be distinctly palpated. No fetal heart sounds or bruit could be heard. The appearance of the mass and the patient's cachexia suggested malignant disease.

An operation was performed August 8. The incision was made in the median line. Firm intestinal adhesions were dissected from the anterior surface of the mass before the enveloping membranes were revealed. Haste being such an important factor on account of the desperate physical condition of the patient, these were simply incised, the liquor amnii evacuated, and a perfectly fresh fetus with the cord and placenta removed. The sac was packed with iodoform gauze to control hemorrhage, and the edges sutured in the abdominal wound. The fetus measured 10.5 cm. from vertex to rump, and was probably alive when delivered.

The patient was almost pulseless when taken from the operating table, but reacted nicely after free stimulation and hypodermoclysis. The temperature and pulse rapidly reached normal; bowels moved on the fourth day. The gauze was removed on the fourth day and fecal matter was found in it. The membranes sloughed away on the eighth day, the fecal fistula persisting. Convalescence was further complicated by the morphia habit previously mentioned. The patient was exceedingly hard to manage and insisted on returning to her home, which she was permitted to do on her promise to have the care of a trained nurse. *At this time, thirty-nine days* after operation, she was able to be about her room and the halls of the hospital. After her return home she declined the attention of a nurse, finally refused nourishment entirely, and died of inanition, Oct. 19, 1903, sixty-seven days after operation.

A thorough autopsy was not practicable, but a sufficient examination was made by Dr. James Ralston to determine the primary seat of the abdominal pregnancy as right tubo-ovarian. The fistulous tract communicated with the rectum and was probably due to a placental attachment at that point.

The condition which this case illustrated is the simultaneous development of an intra-uterine and an extra-uterine gestation. That fecundation is also practically simultaneous in the great majority of cases is borne out by the reports of unimpeachable cases to date. It is the phenomenon of a twin pregnancy, except that the one ovum is arrested in its course before it reaches the uterine cavity. No pathologic condition can be especially charged with its occurrence, except those which obtain in the ordinary cases of ectopic pregnancy. Cases of intra-uterine pregnancy occurring after the termination of an extra-uterine gestation do not come under this classification.

Simultaneous extra-uterine and intra-uterine pregnancy is looked on as a rare condition, and some of the latest text-books on gynecology dismiss the subject with a line and speak of it merely as one of the possibilities. Zinke[1] tabulated 88 cases taken from the collections of B. B. Browne, H. Gutzwiller, John S. Parry, E. W. Martin and Christer-Nilson, to which he adds his own collection with the report of 1 case. Vilsin[2] collected from the literature as far back as the eleventh century 68 cases, to which he adds 1 observation of his own. In 58 per cent. of the cases of this collection the women were between 30 and 40 years of age; 19 per cent. were primiparæ. In only 20 cases did both fetuses arrive at full term; in 47 both aborted, usually one before the other. The death of the mother caused the death of the immature fetus 6 times, i. e., in 10 per cent. of the cases; the intra-uterine fetus went to term in 29 cases, i. e., in 46 per cent. of the cases. In 25 cases, or 37 per cent., the extra-uterine embryo went to full term. Vilsin's most important conclusions are that interruption of the intra-uterine pregnancy had by far a slighter effect on the further development of the extra-uterine pregnancy than vice versa.

Disturbances in the blood circulation in close neighborhood to the uterus caused by rupture or abortion of the pregnant tube, are in many cases responsible for the premature interruption of the intra-uterine pregnancy. The fact that in twenty-five cases the ectopic fetus reached a full term is not considered by Engstrom[3] as a mere accident, but he believes that increased afflux of blood to the pelvis on account of the intra-uterine pregnancy improves at the same time the blood supply of the pregnant tube, thus promoting the development of the ectopic fetus.

At least twenty-five cases of simultaneous extra-uterine and intra-uterine pregnancy may be added to the tabulated record of Zinke, mentioned above. Some of these were overlooked in the preparation of the various collections and additional ones have been reported since the date of his collection on going to print. But it is more than probable that the reported cases of this condition are only a small percentage of those actually occurring. No doubt many cases occur in which the extra-uterine pregnancy terminates without attracting sufficient attention to make a diagnosis or in which the symptoms are overlooked, and the intra-uterine pregnancy continues to term or aborts, or death may happen from the rupture of the ectopic sac, and the intra-uterine pregnancy be undiscovered. Again, there are those cases in which the intra-uterine abortion, in the light of an existing extra-uterine gestation, is supposed necessarily to be the expulsion of the decidua. It is a part of the history of most cases of ectopic pregnancy that the patient expelled something which was supposed at the time to be a miscarriage, and in view of the increasing number of reported cases of a co-existing intra-uterine and extra-uterine pregnancy, it is safe to assume that occasionally instead of the expulsion of the decidua it is the abortion of the intra-uterine gestation. It is also possible that in the early discovery of an ectopic pregnancy the intra-uterine gestation is destroyed by the curettement usually preceding operation on the pelvic organs. At any rate, the condition occurs frequently enough to stimulate a desire to save at least two of the three lives involved. To accomplish this it is most important that an early diagnosis of the ectopic pregnancy be made and the pregnant tube removed by operation. It is not of the utmost importance that the intra-uterine pregnancy be diagnosed, but it is well to keep steadily in mind that the phenomenon of simultaneous extra-uterine and intra-uterine pregnancy does occur, and by the elimination of the preliminary curettement in all suspected cases of a co-existing intra-uterine and extra-uterine gestation, or, better still, in all operations for ectopic pregnancy, an occasional life may be preserved.

Clinical Reports.

VOLVULUS OF THE OMENTUM.*

FRANCIS T. STEWART, M.D.
Professor of Surgery, Philadelphia Polyclinic; Surgeon to Germantown Hospital; Assistant Surgeon to Jefferson Hospital; Out-patient Surgeon to Pennsylvania Hospital.
PHILADELPHIA.

Including my case nine instances of volvulus of the omentum have been recorded in surgical literature. These are as follows:

Case 1.—Male, aged 35 years, a patient of Dr. Alfred Allman, for whom I operated. His mother, a sister and six children are living and in good health. He had never suffered from any serious illness. Four days before operation, while in the best of health, he was attacked by severe abdominal pains, which began in the epigastrium, and which later settled in the right iliac region. He vomited at this time and went to bed. The pain grew worse and the vomiting persisted. I saw the patient for the first time June 19, 1902, on the fourth day of the illness. He was a large, well-nourished man, sweating freely, and evidently suffering severe pain. His temperature was 101 F., the pulse 120, and the respirations 20. There was no hernia. The right side of the abdomen was rigid and the point of greatest tenderness was at the outer border of the right rectus muscle on a level with the umbilicus. The bowels had moved freely just before the time of examination.

A diagnosis of acute appendicitis was made and the abdomen opened through the right semilunar line. The appendix was removed and found to be normal except for three minute hemorrhagic spots beneath the mucous membrane. A further search of the abdomen was made and a mass feeling like a gauze sponge was found well above the incision. It proved to be the right lower corner of the omentum, gangrenous and twisted on itself through 360 degrees. After excision the mass measured six inches long and three inches wide. The peritoneal cavity was flushed with salt solution, and the abdomen closed without drainage. Recovery was uneventful.

The following is a report of the microscopic study of the excised tissue by Dr. Randolph: A large mass of omental tissue, dark in color and showing an abundance of adipose tissue. The mass is twisted longitudinally on itself at the point of amputation. Sections for microscopic examination were removed from the portion beyond the twist and embedded in paraffin and stained with hematoxylin and eosin. There is no necrosis of the adipose tissue. The blood vessels are the seat of extensive thrombosis, especially the smaller veins. Much of the blood in the vessels is extensively disintegrated. In some places there is extravasation of the disintegrated blood and pigment which infiltrates the neighboring connective tissue. The changes are those which would be brought about by interference with venous return.

Case 2.—Oberst,[1] 1882: Male, aged 35 years. Right inguinal hernia for 12 years. Symptoms of irreducible hernia for two days before operation. The diagnosis before operation was irreducible hernia. At operation the sac was found to contain incarcerated omentum due to torsion, the torsion being entirely within the hernial sac. The probable etiology was forcible attempts at reduction.

Case 3.—Bayer, 1898: Female, aged 54 years. Left inguinal hernia 15 years. Following an attack of coughing there were severe pain in the hernia and a feeling as if a round object were revolving inside it. On the following day a diagnosis of strangulated hernia was made and operation undertaken. The omentum was found adherent to the mouth of the sac by a band forming one support, the other being the intra-abdominal pedicle of the omentum. Around these two points the omentum was revolved just as a triangular handkerchief that is held at two ends could be, the pedicle being twisted four or five times on itself. There was beginning gangrene of the omentum at the peripheral end, which was pushed back through the inner half of the hernial ring. The probable etiology was a severe attack of coughing.

Case 4.—Baracz, 1900: Male, aged 42. Left inguinal hernia for several years. Symptoms were those of strangulated hernia and a diagnosis was so made. The lower part of the omentum was thickened, dark in color, and turned several times around its axis. The hernial sac was empty except for some clear fluid and a band which ran from the base of the sac up through the inguinal canal into the strangulated omentum. The probable etiology was lifting a heavy trunk, followed by attempts at taxis.

Case 5.—Peck, 1900: Female, aged 37 years. Right inguinal hernia for 12 years. The symptoms were abdominal pain, vomiting, and slight fever. A tumor could be felt in the abdomen, and a diagnosis of suppurating ovarian cyst was made. The tumor was made up of the entire omentum, a tightly twisted pedicle being found just below the transverse colon. There was no connection between the hernia and the omentum, but there were some old adhesions between the omental mass and the right ovary. Microscopic sections showed chronic inflammatory changes and the extravasation of beginning strangulation. Etiology unknown.

Case 6.—Hochenegg, 1900: Male, aged 41 years. Right inguinal hernia for 30 years. Twenty-four hours before the onset of symptoms the hernia became larger and could only be reduced with the greatest difficulty. The symptoms, which were present for two days before operation, were abdominal pain, distension, vomiting, fever, and a mass in the right iliac region. A diagnosis of appendicitis had been made. The tumor consisted of strangulated omentum, was the size of a man's head, was nowhere adherent, and had a slender pedicle twisted on itself three times from right to left. The probable etiology was attempts at reduction of the hernia.

Case 7.—Wiener, 1900: Male, aged 79 years. Right inguinal hernia for 30 years. The symptoms were pain in the right iliac region, which had come on suddenly four days before operation, slight fever, and a tumor in the right abdomen. A diagnosis of intraperitoneal abscess was made. A piece of omentum as large as the palm of the hand and dark blue in color was found. Its distal portion was adherent to an epiploic appendage on the ascending colon and its proximal portion was continuous with the remainder of the omentum by a narrow pedicle, which was twisted on itself five or six times, causing strangulation of the portion of the omentum affected. Etiology unknown.

---

* Read before the College of Physicians of Philadelphia.

[1] Cases 2 to 7, inclusive, are abstracted from Weiner's valuable paper on "Intra-abdominal Torsion of the Omentum," Annals of Surgery, November, 1900.

Case 8.—Baldwin,[2] 1902: Male, aged 47 years. Hernia not present. Typical symptoms of appendicitis were present for three days. No tumor could be felt. A diagnosis of acute appendicitis was made. The omentum was rolled up so as to make a distinct tumor with a small pedicle, which was twisted on itself eight times, the entire mass being about the size of a large fig. Etiology unknown.

Case 9.—Blake,[3] 1903: Male, aged 45 years. Right inguinal hernia for 20 years. Three days before admission he had pain in the right side of the abdomen and in the hernia. Attempts at reduction were unsuccessful and painful. The lower right quadrant of the abdomen was filled with a mass which reached to the middle line. A diagnosis of probable appendicitis, with a peritonitis spreading into the hernial sac, was made. The omentum was gangrenous and twisted through four and a half turns at its attachment to the transverse colon, constricting it to a rope-like mass one and one-fourth inches in thickness and four inches long. The lower end of the omentum entered the sac of the hernia and had been retained there by the thickness of its extremity. Probable etiology, attempts at reduction of the hernia.

Summary.—Seven of the cases were males, two females. The ages of two were 35, one 37, one 41, one 42, one 45, one 47, one 54, and one 79. The omentum was connected with the hernia in five of the seven cases in which a hernia was present. The symptoms were acute in all and pointed toward some serious intraperitoneal lesion. The diagnosis was not made in any case; two were diagnosticated strangulated hernia, one irreducible hernia, four appendicitis, one intraperitoneal abscess, and one suppurating ovarian cyst. The tumor could be palpated in five; in four no tumor could be felt. There seems to be no way suggested by which a diagnosis may be reached. A movable, doughy tumor coming on quickly after attempts to reduce a hernia should make one suspicious of omental torsion. A count of the leucocytes may contribute in differentiating this condition from an abscess. A blood count was not made in any of the above cases. In all of the cases the importance of immediate operation was recognized. The extent of omentum involved varied from a portion, the size of a large fig, to the entire omentum forming a mass the size of a man's head. The tip of the omental mass was fixed in six cases, thus forming two supports between which the omentum might turn. The cause of torsion was forcible attempts at reduction of a hernia in four instances, severe coughing in one, and unknown in four.

Comments.—It is easy to understand how a twist in the omentum may be produced by forcible taxis of an epiplocele, by cysts or tumors of the omentum which develop irregularly, by a careless operator who fails to smooth out the omentum after an abdominal operation, and by contraction of the abdominal walls or movements of the intestine in those cases in which the tip of the omentum is adherent, but the explanation is difficult in those cases in which an apparently normal omentum revolves on its own axis in an apparently normal abdomen, as in two of the reported cases. As the result of experiments on animals, Payr[4] is convinced that overdistension of the spirally disposed veins of the omentum would produce a twisting of that structure.

Weiner[1] emphasizes a practical point of some value in those cases of hernia in which there have been symptoms of strangulation and in which only a strand of omentum is found in the sac at the time of operation, by insisting on a thorough investigation of the intra-abdominal portion of the omentum for torsion.

A study of these cases impresses on us an additional danger in employing forcible taxis and serves to fortify the conviction already formed that strenuous efforts to reduce a hernia are exceedingly hazardous.

TWO CASES OF INFANTILE MYXEDEMA

JAMES FREDERICK CLARKE, A.M., M.D.
FAIRFIELD, IOWA.

There are no less than six cases of infantile myxedema, resulting in a cretinoid condition, in Iowa, and probably many more. Since the condition is frequently unrecognized, it is possible that the accompanying photographs of the two cases occurring in my practice may help to call attention to the value and importance of early treatment.

Case 1.—E. M.[1] was first seen when 20 years and 4 months of age (Fig. 1). Thyroid feeding was at once begun. Improvement was rapid even at this late age. In the first 18 months the increase in weight was 13½ pounds, and in height was 5¾ inches (Fig. 2). She now, at nearly 23 years of age, appears as a bright active child of 7 or 8 years, with, since treatment was begun, an entire new growth of hair, new teeth and a normal soft skin.

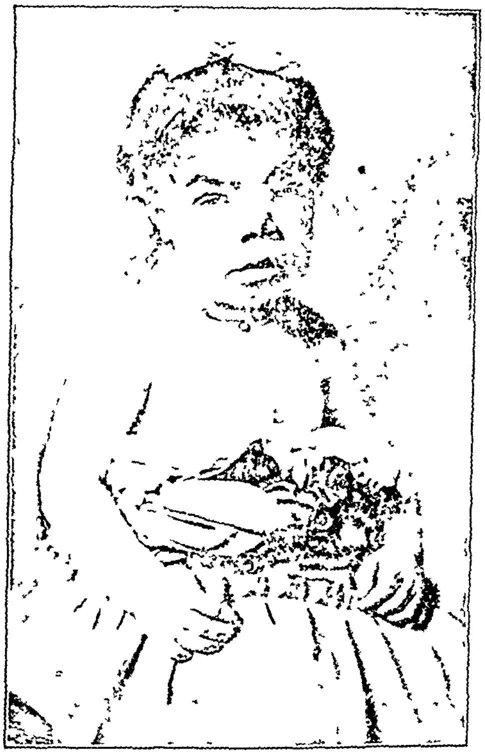

Fig. 1.—Case 1. E. M., age 20 years and 4 months, at beginning of treatment.

Case 2.—P. B., born in Iowa, was seen first when 8 years and 5 months of age (Fig. 3). Her family history was good. The mother gives the past history as follows: The labor at her birth was easy, no physician being present. The baby weighed 9 pounds. At two weeks a "blood tumor" appeared on the forehead and grew to the size of a walnut. At 4 months this tumor was removed under chloroform anesthesia. Whooping-cough was the only other sickness until she was weaned and began teething at 18 months of age. At 18 months she was "sick all winter," lying in her buggy all the time, and having a yellow color. Teething continued to the sixth year. She has never walked except by holding to chairs, and has never learned to speak but a few words. She has had alternating diarrhea and constipation and at times vomiting. Though always sleeping well, she eats very little, at many meals not more than two teaspoonfuls of food. She has never had spasms and the eyes have never been crossed.

4. Archiv f. klin. Chir., vol. lxviii, No. 2, 1902.

1. Reported with early photographs in the Medical Fortnightly, May 26, 1902.

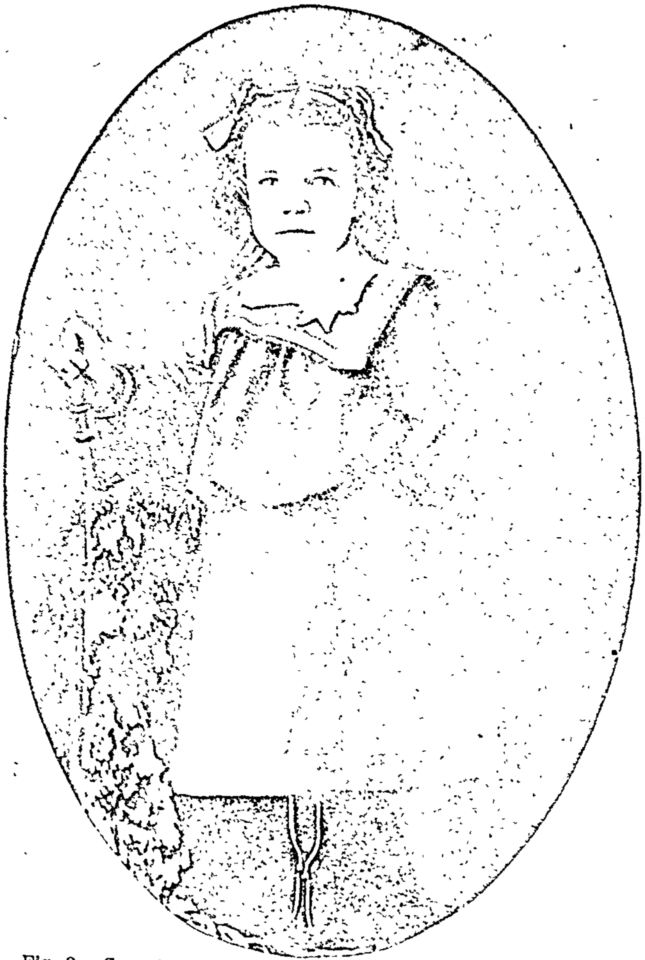

Fig. 2.—Case 1. E. M., age 21 years and 11 months, after one year and seven months' treatment.

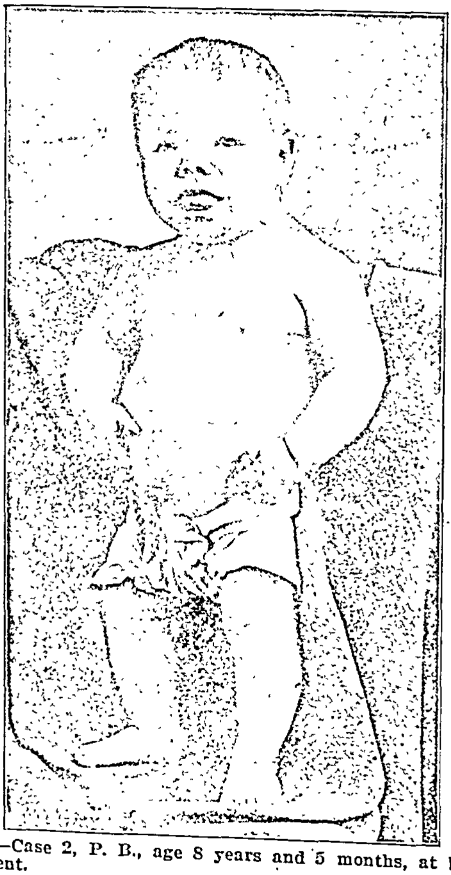

Fig. 3.—Case 2, P. B., age 8 years and 5 months, at beginning of treatment.

When first seen, Nov. 25, 1902, this child, 8 years, 5 months old, had the fontanelle open. The suture lines of the skull were depressed. The thick tongue protruded and the saliva constantly dribbled from the mouth. The child would sit continually in an apathetic condition or would stand supported by a chair. The hair was coarse, the skin dry and wrinkled, and only first teeth were present. The abdomen was prominent, the legs bowed and the spine curved so that the chin rested on the thorax.

Thyroid feeding was begun at once. Beginning with one-half of one tablet after each meal, the amount was rapidly increased until two tablets were given three times a day. In two weeks she became brighter and more active. There was at first a loss in weight and then a rapid gain.

In one year from the beginning of the thyroid feeding, the gain in weight has been 14 pounds, and the gain in height 7¼ inches (Fig. 4). Two new teeth have appeared and her hair is all new and soft. She runs about, eats well and is learning to talk. The photographs show better than words the transformation.

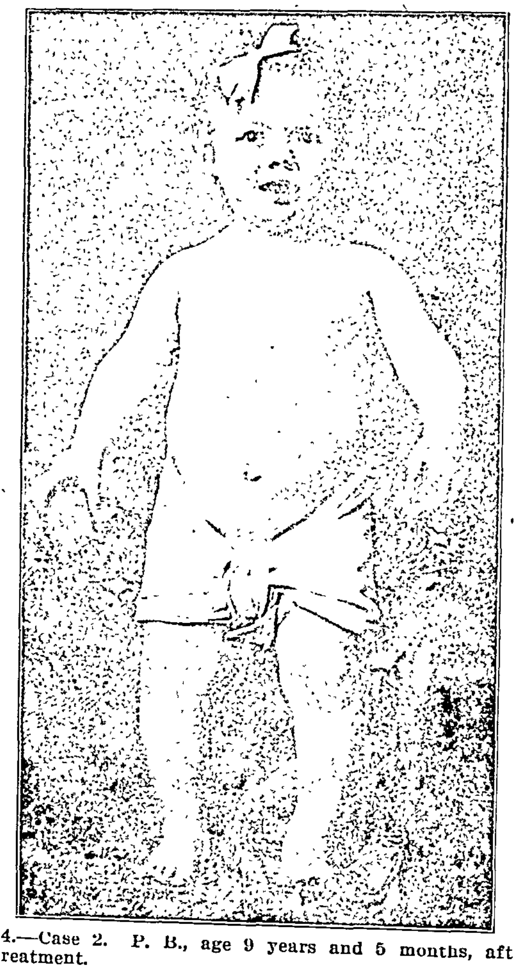

Fig. 4.—Case 2. P. B., age 9 years and 5 months, after one year's treatment.

A Tropical Clinical Thermometer.—Baldwin describes in the London *Lancet* (January 30) a thermometer to take the temperature of a patient when the atmospheric temperature is greater than that of the patient. The ordinary clinical thermometer can not be shaken down below the register of the atmospheric temperature. The new thermometer is made without the stricture or bend for registration. It is, therefore, a minimum thermometer, that is, it will register the lowest temperature. The thermometer is made longer than ordinary, so that it may be read without removal from the mouth or axilla, because it will commence to change immediately on removal. It also has a vacuum bulb at the distal end to provide against expansion, as ordinary thermometers sometimes burst when the temperature reaches 110 degrees.

THE MEDICAL WORK IN HOSPITALS FOR INSANE.

An important treatise by Dr. Paul Sèrieux on the care of the insane in France, Germany, Switzerland and Italy, is being issued by the Municipal Press of Paris. We are accustomed to the difficulties in the medical administration of American hospitals for the insane, and are prone to think that they order these matters better in France; but it is interesting to find that precisely the same difficulties as our own confront the physicians in charge of foreign hospitals.

Dr. Marandon de Montyel, the head of a large asylum, is quoted as saying that if he and all of his colleagues were frank they would confess that it was impossible for them to know their own patients. Another physician, Dr. Brousse, asks how a medical superintendent can know his patients, when they number from six hundred to fifteen hundred. After showing that in order to examine an average number of nine hundred patients once a week, a man can devote only three minutes to each case, he ironically inquires: "How can one in three minutes make a minute psychologic analysis, an extensive physical examination, an inquiry into antecedents and heredity, and then proceed to gain the confidence of his patient and prescribe the proper course of treatment? In the face of this manifest impossibility, the only thing to do is to select certain cases, and naturally one chooses the most interesting. The others are left to their madness. The acute cases become chronic, and remain permanent inmates of the asylum which they cumber."

Dr. Sèrieux makes a sweeping indictment against the large institution, saying: "Thus it is true that not only are many of the insane not given treatment, but they are allowed to become—I had almost said they are made—incurable when they might have been cured. And the number of these is relatively large. Under such circumstances, an insane patient who recovers does so because of his own recuperative powers, for he has nothing to depend on but the vis *medicatrix* naturæ. Fortunately this is sometimes powerful enough to repair the ravages which the ignorance and stupidity of men only succeed in aggravating *instead* of checking."

The physician, according to this authority, is reduced to the rôle of registrar, farmer and hotel keeper. If a farming establishment is connected with the asylum, he will superintend its operations. He must be responsible for the bakery and the kitchen, and above all he must sign stacks of papers and certificates, which, however, are really given out blindly; he must keep elaborate records when he ought to be examining and caring for his patients. Every day he makes a visit to the wards. And what a visit! A review *en bloc et au galop*, like a colonel passing in front of his regiment, a summary, hasty inspection which has fully as much to do with the conditions of the ward as of the patients. The *mise en scène* of this function is often carefully arranged to enhance the dignity of the superintendent. "But," Dr. Sèrieux asks, "what is the use from a medical point of view of this procession, with the superintendent at the head, followed by an escort of assistants, nurses and attendants? Such a visit is as inefficacious as it is ceremonious. It takes cognizance chiefly of the noisy patients, may have a subduing influence over them, and has been felicitously called 'police therapeutics.'"

Whoever is familiar with the American hospital for the insane must recognize that this description applies well to many of them. The great problem of hospital administration in the United States, as in France, is how to restore the physician to his rightful domain. At present in America, the physician in charge is made general superintendent, in an effort to avoid a clash of authority between a medical head and a business manager. Various other experiments have been suggested and even tried. We have had the business superintendent with a medical staff supposedly supreme in its sphere, yet necessarily limited and unauthoritative. From this we have quickly swung back to the usual plan of a physician-superintendent.

Three states, Iowa, Wisconsin and Minnesota, administer the affairs of their charitable and even penal institutions by boards of control, consisting of paid officials appointed by the governor of the state, and whose duty it is to make purchases and contracts for the whole group of institutions under their charge. The theory underlying the creation of such bodies is, of course, that the centralization of responsibility which the business world has found so effective and profitable, will prove equally advantageous in public financial operations. But from our point of view its most important result is, that if properly administered, such a board would free the superintendent from many of the irksome non-medical cares which now infest his day. The work of such boards has been, perhaps, too brief and too limited by various circumstances for us to be able as yet to judge fairly how far they can effect this object.

Doubtless the most intelligent experiment in this country is shown in the New York Lunacy Commission. The material care of the 23,000 insane persons who are the wards of the State of New York is in itself an enormous business, justifying the application of the most approved business methods, and it was natural on that ground alone that there should be an effort to make purchases in the largest quantities and at the lowest rates. The commission, as is well known, consists of three salaried commissioners, one of whom is a lawyer, and one of whom must be a physician. Observers of New York conditions have viewed with some concern the recent tendency to make the commission more and more bureaucratic. The question is a nice one: How to secure centralized responsibility in business matters, how to correlate the medical work of the various institutions, how to secure a general medical *esprit dé corps,* yet without sacrificing the personal responsibility and power of initiative which the physician must retain.

To our minds the whole subject of institutional administration deserves from the profession a degree of attention it has not received thus far, and the fact that the same difficulties are felt the world over only emphasizes this need.

THE TREATMENT OF PNEUMONIA.

What is needed in the treatment of pneumonia is not more drugs, but the discriminating and intelligent use of those we have. We need to steer clear of therapeutic nihilism on one hand, and of overdoing and polypharmacy on the other. To declare, because there is as yet no specific for the disease, that drugs and medical treatment are valueless, is as absurd as it is to pour useless or even harmful drugs into the patient as soon as the diagnosis is made.

The temptation to overtreat is great. Recognizing the grave nature of the malady, knowing its rapid course and its tendency to suddenly developing complications, importuned by anxious friends to relieve annoying symptoms and to keep doing something, we too often yield to the pressure and, before we are aware, have gotten into the narrow path of treating the disease and not the patient. We soon begin to talk of "my treatment for pneumonia," and we are humbugged into believing in the efficacy of our pet remedies, though to an outsider it is clear that too often we are doing harm. It would be a fine clinical lesson if each medical student before graduation could have the chance of watching, say one hundred cases of pneumonia—and of other acute infections, too—and thus have the lesson of the tendency toward spontaneous recovery firmly ground into his mind. It would be most valuable capital on which to begin his practice of treating infectious diseases.

On the other hand, the physician who has seen cases die—and he is generally a hospital physician—in spite of medicine, and other cases recover without any drug at all, is apt to become skeptical and declare that there is no treatment for pneumonia except for its surgical complications, and that the patient's only hope is in his resisting power, the *vis medicatrix naturæ.* Such a view is as narrow-minded and ridiculous as the opposite; such practice has had the negative virtue of not being directly harmful, but its sins of omission may be many.

The treatment of pneumonia is discussed in a judicial tone by Dr. Gilman Thompson in this issue of The Journal.[1] His advice regarding the general uselessness of expectorants, external applications and the so-called specifics, is timely. This advice has been given many times, yet it will, we fear, be thought by many readers to apply to the other fellow. But if the cap fits, let us put it on. How can we consistently and conscientiously give to our patients enormous doses of digitalis, creosote, guaiacol, sodium salicylate, etc.—doses that if given to him in health, we should declare were toxic and plainly responsible for nausea, vomiting, cardiac weakness, albuminuria, delirium and other untoward symptoms? Yet we pour in the huge amounts because we have seen—probably in an abstract—that some one, usually an obscure writer, but with a German name, has declared his belief in the efficacy of such and such a medicine. Thompson, it will be seen, believes in drugs. He knows, as does every physician of experience, that he has saved lives by their timely use. But he warns against the overstimulation of the heart, against overfeeding, against the too free use of that two-edged sword, morphin. Morphin in pneumonia, by the way, always seems to us like the revolver in the home—a weapon that should be kept on the shelf out of reach of the children, for while of inestimable value at the right time, it is capable of doing incalculable harm, and only the experienced ones should handle it. The constant annoying of the patient by too frequent sponging, moving, giving of food, medicine, etc., is a point that should be brought home to us all. Rest and sleep are sometimes of far greater value than drugs.

Why can we not have for pneumonia, as for typhoid, a few broad general principles of treatment? Why not admit that at present there is no specific, and so stop the indiscriminate and harmful practice of overdrugging? A therapeutic nihilism, on the other hand, is equally bad. Drugs and other remedial measures are indispensable, and properly used save lives, but they should be employed only when needed, and then as needed by the particular case in hand. Let there be individualization in the treatment of this disease.

SOLUBLE BACTERIAL TOXINS.

When Roux and Yersin discovered that the filtrate of an old broth culture of diphtheria bacilli is strongly toxic for guinea-pigs; and when it was later shown by Behring that the serum of an animal which had been repeatedly injected with small and gradually increasing quantities of this toxin is capable of protecting another animal against a fatal dose of the toxin or of living diphtheria bacilli, it was thought that the problem of infectious diseases had been solved. It was soon found, however, that these discoveries are not capable of universal application because, aside from the diphtheria bacillus, the bacillus of tetanus is the only organism that has thus far yielded a powerful toxin when grown in the ordinary culture media. In the case of other organisms, the experience has been that, not having a toxin to work with, it has been impossible to prepare a satisfactory antitoxin. Of late years, numerous attempts have been made to get soluble toxins from other bacteria by growing them in specially prepared media or by treating the organisms in a special way after they have been scraped off a solid medium on which they were grown, and some of these efforts have been crowned with a fair degree of success.

---

[1] See page 747.

Brieger and Mayer have found that typhoid bacilli when grown on a solid medium, scraped off and macerated for several days in a weekly alkaline solution of ammonium sulphate, give off specific substances which are capable of imparting strongly agglutinative and bactericidal properties to the serum of an animal that is repeatedly injected with the sterile solution. These solutions, although they contain specific bacterial products, are not toxic for experimental animals. and it seems that they for that reason can be of no great value in the preparation of an antityphoid serum which can be used successfully as a therapeutic agent. Conradi macerated typhoid bacilli and dysentery bacilli in .85 per cent. salt solution, and thus obtained solutions that were highly toxic for rabbits and guinea-pigs. The suspension of bacilli in salt solution is kept at incubator temperature for twenty-four to forty-eight hours, and under these conditions the bacilli undergo autolysis, liberating the toxins which are contained in their bodies. Macfadyen and Rowland, as we have pointed out,[1] prepared a highly toxic extract of typhoid bacilli by grinding up the organisms at a very low temperature and exhausting this mass with physiologic salt solution. More recently,[2] they have applied this method to streptococci, to *Staphylococcus pyogenes aureus, Bacillus enteritidis, Bacillus tuberculosis* and *Bacillus diphtheriæ* with equally satisfactory results. A 10 per cent. extract of streptococci, for instance, killed guinea-pigs within six hours when 0.1 c.c. was injected intraperitoneally. The results with staphylococci and *Bacillus enteritidis* were equally favorable.

Several attempts have also been made to get soluble streptococcus toxins by growing a virulent organism in special media. Marmorek prepared a medium containing glycocol and leucin, and asserts that he obtained a powerful toxin in this medium. The streptococcus, which was very virulent, was allowed to grow in the medium for eight days, when the culture was filtered and the filtrate tested on rabbits. The streptococcus used in these experiments had its toxin-producing power augmented by growing it for several generations in a leucocyte exudate obtained from a guinea-pig which had been injected with several doses of antistreptococcus serum. Besredka grew a virulent streptococcus in heated rabbit's serum, and thus obtained a special hemolysin secreted by the streptococcus, in the filtrates, but these filtrates were not toxic for rabbits. Recently, Simon[3] also prepared a toxin by growing streptococci in special media for three to eight days and filtering. He obtained leucocyte exudate from the pleura of rabbits, centrifugated the leucocytes out, and grew the streptococci in this liquid or in a mixture of it and bouillon. Filtrates from the cultures killed rabbits in doses of 2 to 7 c.c., but the time of death was very indefinite, varying from two to twelve days. Simon believes that a streptococcus, in order to secrete toxin, must meet a certain resistance to its development in the medium in which it is grown, and that this resistance is furnished by something in the leucocyte exudate. It seems now that those organisms which have been supposed not to secrete a soluble toxin do after all secrete their poisons, but in some instances, at least, they must be stimulated by the animal cell juices before they secrete toxins. It now remains to be seen whether or not it will prove possible by means of these specially prepared toxins to secure potent antiserums with actual therapeutic powers—the ultimate good of all this work.

PROFESSOR EHRLICH'S VISIT TO CHICAGO.

Next week the University of Chicago confers honorary degrees on a number of distinguished German scholars. The representative of German medicine selected for this conspicuous honor is Prof. Paul Ehrlich, director of the Royal Institute for Experimental Therapy at Frankfurt a. M. Ehrlich's name is one of the most familiar in the medical annals of our day. His earlier investigations into the morphology of the blood, and especially his differentiation of leucocytes, are known to every physician. His real fame rests on his theoretical investigations of the fundamental problems of immunity. A backward glance through the editorial pages of THE JOURNAL will show quickly the extent to which the Ehrlich lateral or side-chain theory has dominated the researches in this field during the last few years. This theory has not only made clear to us many observed phenomena, but has also been fruitful of important investigations, the results of which have been and will continue to be of great significance to therapy. Ehrlich's method of quantitative measurements of diphtheria toxin and antitoxin has been of the greatest service in serum therapy, at the same time as it has led to the establishment of the chemical nature of the interaction of these substances. It is of great interest to watch the steady growth of the chemical conception of the mode of action of the toxins, lysins and antibodies that have come to our knowledge within recent years. To Ehrlich will belong the great honor of the first fruitful theoretical foundation of the new science of immunity. Certainly the outlook for further results of direct therapeutic value from research in this field is most promising.

[2] Centralbl. f. Bakt., xxxv, 1904, 415.

[3] Centralbl. f. Bakt., 1904, xxxv, 440.

Since Ehrlich came to Frankfurt to direct the newly established Royal Institute for Experimental Therapy, many brilliant researches have been carried out under his supervision, and among them are certain noteworthy ones by American workers. In addition to research, the institute exercises governmental control of the curative and other sera manufactured in Prussia. All sera placed on the market must bear the imprint of having been found by this institute to be pure and to reach certain standards. This is a most important function. It guarantees the public the best products of serum therapy—an official guarantee that is not yet provided in this country.

A short time ago special arrangements were made whereby the scope of the institute was enlarged so that it could take up the problem of the etiology of cancer. Some results of this line of work have already been published, as, for instance, observations on epithelioma contagiosum in fowls, which is shown to be caused by a most interesting filterable, hence, probably, ultramicroscopic virus.

We understand that on March 21 Professor Ehrlich will deliver at the university a public address on "Modern Theories of Toxins and Antitoxins."

When the University of Chicago invites Professor Ehrlich to come to this country to receive an honorary degree under the circumstances mentioned, it is investigation in medicine that is placed on high as one of the ideals of German scholarship. We as a medical profession gladly join with the university in this recognition. To Professor Ehrlich we would express a deep sense of indebtedness for his devotion of his great gifts to theoretical investigation which has brought results that vitally affect human welfare.

DRUGGIST ETHICS.

There was a time when the drug store was really an apothecary shop for the dispensing of drugs on prescription of physicians. Now the average city drug store, at least, has become a bazar in which almost everything under the sun, and a few other things beside, can be purchased at cut prices. There are undoubtedly many things apart from the materials used for prescriptions that might properly find a place in a drug store. But the present heterogeneous collection of things so overshadows the original purpose of the institution that it is easy to understand how prescription filling becomes a very secondary department, with consequent neglect of due attention to this originally most important function, and there follow the evils of substitution, since the already crowded store has no room for the variety of drugs that may legitimately be called for.

There is another phase of present customs in the drug store that is even more striking and less desirable. Druggists' windows are usually covered with signs and advertisements recommending patent medicines and disgusting references to and indorsement of "lost-manhood" fakes and abortifacients. One is apt to find such catching phrases as "We recommend So and So's tonic," or "We know the value of Dr. X's cough medicine," or "Dr. Y's Successful Prescription for Women. Come in and let us tell you about it." Or, "Ask the drug man and he will tell you what to take for that cold," or "that backache." Sometimes these are illuminated announcements, which presumably show the personal interest of the druggist in these remedies. In a few cases, where such announcements have been noticed, the tonics so plausibly recommended contain nearly as much alcohol as the whiskey that is sold over the bar in the ordinary saloon. As the amount to be taken is from three to six tablespoonfuls, that is, one and a half to three ounces a day, it is easy to understand how some women, and what is, if possible, worse, some children, acquire the liquor habit in what is presumed to be an incomprehensible way.

The majority of druggists in our large cities now seem to consider it the proper thing, not only to push nostrums of others, but to have those of their own, or at least those that bear their names. None of these remedies is, as a rule, such as can be taken with impunity by the ordinary patrons of a drug store. The cough medicines are often a favorite remedy of incipient consumptives, and as they usually contain opium, they tend to lock up the bowels, decrease the appetite, lessen the secretions and consequently lower resistive vitality, while they make the chances of reinfection by keeping infective material within the lungs much greater than before. With regard to headache powders, there seems to be no doubt that some of the increase in the sudden death rate in our large cities noted in the last ten years is due to the careless and frequent employment of depressant coaltar remedies which are so easy to procure under the name of headache powders.

Beside this, many druggists consider it perfectly proper to give medical advice with regard to supposed minor ailments. There is certainly no physician doing work in the dispensary service of a large city who has not had cases of pneumonia, especially in young strong patients, who have applied to druggists and obtained some remedy that for a time has delayed their application to a physician for treatment. Needless to say, if the delay is long, that is, if the patient is encouraged to remain on his feet for twenty-four to forty-eight hours after he has felt the first symptoms of his affection, the prognosis of the case is extremely unfavorable. There are other classes of cases, especially the beginning infections, such as typhoid fever and even smallpox, where the facility with which a druggist prescribes for symptoms keeps patients from applying to a physician and learning their true condition before inflicting fatal injury on themselves or causing great danger to others.

It is very evident, then, that medical practitioners who have the good of their profession and the health of the community at heart, must discourage these unethical practices. It is no use to say that rents are so high that druggists must do much more business than that which comes to them in the filling of prescriptions and the proper dispensing of drugs. The reason why rents are so high is that druggists insist on having their stores on important business corners for the purpose of attracting the class of trade who buy the unethical goods they sell. There is no reason why properly conducted drug stores should not occupy much less conspicuous places than those which are now the favorites, and by so doing revert to the ethical institutions they were before. Commercialism has invaded entirely too much the proper domain of drug dispensaries, and it seems time for concerted action on the part of the medical profession to bring about the necessary reform. Meantime, much may be done to discourage the growing evil if physicians will encourage the filling of their prescriptions at pharmacies, where more attention is paid to the proper dispensing of legitimate medicines than at the almost department-store variety shops that maintain a counter for prescriptions, but very evidently consider this an entirely secondary feature of their business.

AUTO-DISPENSING.

The custom of dispensing medicines has been much more general among British practitioners than in this country. In fact, in a large practice it is not infrequent there for a physician to employ a special dispenser or pharmacist to put up his prescriptions or to prepare the drugs for use. Legislation now proposed would prohibit all such dispensing of medicine by physicians, except in remote country practice and in emergencies, etc. Naturally, this has raised a storm of protest. Such a measure has been a law, we believe, in France for some years, and it is reported not to work entirely satisfactorily; it is found that its advantages are not so many as its disadvantages. The druggist is apparently the principal gainer by the change. It is a truth that the art of prescribing is being to a certain extent lost, but, on the other hand, there are immense disadvantages in the prohibition of auto-dispensing. The ultimate result of such a law would probably be to send many patients to the prescribing druggist, and thus greatly increase the use of patent and advertised proprietary remedies.

THE COLD WINTER AND THE MORTALITY RATE.

Pneumonia, which is becoming the leading disease factor in the mortality of the present day, is a disorder that is very decidedly influenced by the external temperature and by the changes of temperature. The winter just closing, which has been almost a record one, and one which would show perhaps a greater amount of steady average cold than any other winter in the last twenty or thirty years if the month of November were included within the three winter months, has been a potent cause of much of the pneumonia mortality. According to a New York newspaper, the bacteriologic department of the Board of Health of New York City has investigated the subject of the contagion of pneumonia, and finds that contagion bears comparatively little importance to the spread of the disease. The board is inclined, therefore, to attribute the excessive death rate from pneumonia to the cold of the past winter. Of course, this is a factor additional to the influences, whatever they may be, which have been active in producing the greatly increased pneumonia mortality over the past ten or fifteen years. It is probable, therefore, without going into the field of prophecy, that the mortality, especially among the older and more feeble members of the community, during the coming spring months will be very much increased, largely through lung disorders, chiefly pneumonia. The reaction after a period of intense cold, such as has been the case, is likely to be a somewhat serious one, and many will succumb. The green winter is not always the one that makes the fat churchyard.

A SAFE FOURTH OF JULY.

The annual protest against the useless destruction of life and limb in the Fourth of July celebrations, instead of dying out last fall when deaths from tetanus ceased to occur, has been prolonged into a campaign. The startling statistics which we printed last August,[1] are still being referred to by the press; the matter is still being agitated in various parts of the country, and the indications are that there is more than a superficial interest in the saving of a good holiday from a bad usage. What might be substituted for the present noisy demonstration was the subject of a meeting of the Ravenswood (Chicago) Woman's Club recently. Segregation was suggested, a space being allotted to those who must burn powder, where, with a supply of physicians, they might celebrate in the old way, while other people celebrated in a quieter and more appropriate manner. Public meetings, speeches, picnics, music, and the instruction of children by their parents in the duties of citizenship—in other words, going back to the old and sensible method of celebration—was another suggestion. While there is not much in this program to entice a real boy from his firecrackers and revolver, the day might be so arranged, with games, picnics and various unusual occurrences, in which all the family, cousins, uncles and aunts join, as to leave no chance for him to miss firecrackers. The segregation idea is a good one. If the parents in a town or in a definite section of a city would agree to taboo fireworks—except in a certain described and limited locality—and to have a full day of celebration in other ways, the children would doubtless enjoy the day and have no regrets over the lost opportunity to burn powder and fingers.

TUBERCULOPHOBIA IN FRANCE.

Under a recent ruling of a commission appointed by the minister of the interior of France, consumptives in public hospitals must be kept isolated from the other patients. In January, the minister of the interior sent to the various local authorities circulars calling on them to give instruction to the hospital authorities to observe this rule of isolation. According to this rule, there must be no direct or indirect relation or association between the tuberculous and non-tuberculous, and the attendants and physicians having the care of the tuberculous must abstain from having anything to do with other patients, or at least must change clothing and be disinfected when they are obliged to change from one service to another. The practical difficulties of carrying out this rule are shown in an editorial in the *Semaine Médicale,* February 10. It points out that the regulation is far more strict than those now observed in regard to diseases much more seriously contagious than tuberculosis, and that this is the first time that any such rigid rules have been adopted anywhere, at least under the direct sanction of the government. The frequency of tuberculosis and the manifold forms in which it appears, the variations of its severity and the fact that probably a very large proportion of the population is more or less affected, or has been, would seem to point to the absolute impossibility of such strict and efficient isolation as is here apparently attempted. It would seem that tuberculophobia has gone farther in France than elsewhere.

THE FICKER TYPHOID TEST.

The application of the Gruber-Widal reaction to the diagnosis of typhoid fever has done much to clear up obscure cases, especially in hospital practice. The technic of the test is not especially difficult to acquire, but the necessity of having constantly on hand fresh and virulent cultures of the typhoid bacillus makes it practically impossible for the general practitioner to use the reaction directly; if he avail himself of the advantages which the application of the Gruber-Widal reaction affords, he must either have a bacteriologist come to his patient, or he must send some of the patient's blood to a central laboratory where special cultures of the typhoid bacillus are kept ready for the purpose. Too often the cultures in such laboratories cease to be suitable for the test, or the blood is given to an assistant who does not take the necessary pains to ensure a reliable report; just where trustworthy information is most needed, it may be wanting. Last year Ficker[1] recommended the use of a fluid containing dead typhoid bacilli from cultures of known origin and virulence instead of the bouillon cultures of living bacilli, twenty-four hours old, ordinarily employed. He maintained that the serum from typhoid patients agglutinated the dead bacilli very definitely, and that the procedure had numerous advantages over the ordinary Gruber-Widal reaction. Clinicians were at first somewhat skeptical with regard to the value of Ficker's test, but in a number of hospitals it is being tried and the results thus far have been favorable. J. Meyer,[2] working under Hansemann's direction in Berlin, finds Ficker's test even more reliable than the Gruber-Widal reaction, probably on account of the greater constancy of the virulence of the bacilli used in the manufacture of Ficker's fluid. In two cases of typhoid, in which the ordinary Gruber-Widal reaction was doubtful, the Ficker test gave a positive result. The new method has the great advantage of convenience. The test can be made by any physician in his office as easily as one can examine a sample of urine for the presence of sugar. No thermostat is required, no living culture of typhoid bacilli, no complicated technic. All that one needs beside the Ficker's fluid is a bottle of salt solution, a cupping glass, a glass pipette and a few test tubes. Merck of Darmstadt has put the fluid, together with the apparatus, in convenient form on the market. The method will doubtless be applied in the near future by many clinicians. Should the reports be as favorable as those thus far made, a decided step forward in typhoid diagnosis will have been taken.

TUBERCULOSIS AND PREGNANCY.

While it is the exception for tuberculosis to be transmitted directly from parent to child by heredity, a type of cell of lessened resistance and augmented susceptibility may be thus transmitted. In addition, the offspring of tuberculous parents is exposed to the danger of direct infection with tubercle bacilli expelled with the broken-down products of the morbid process. For these reasons the tuberculous patient should not marry, or if a married person be tuberculous procreation should be avoided, particularly in the case of women. Although it was at one time thought that pregnancy has no influence on the course of tuberculosis, or even has a beneficial influence, a better knowledge of the facts shows that it has really a most deleterious influence. From a study of this question, Dr. Wilhelm Hahn[1] expresses forcibly the opinion that pregnancy is a severe complication of tuberculosis, and the more so the more frequently it is repeated. He advises that in the conflict with tuberculosis as a disease of the masses, the question of preventing conception in tuberculous women should receive the most serious consideration. If pregnancy has occurred, the woman should be kept under constant medical observation. If aggravation of the tuberculous process take place, abortion may be induced with the consent of the woman and the sanction of a consultant. The life of the mother is to be considered as of more value than that of the child. In the later months of pregnancy, the induction of premature labor offers no advantage over delivery at term, and in the case of a tuberculous woman is a procedure of no small degree of gravity. As, moreover, a tuberculous woman may give birth to a healthy child, which, if placed under suitable environment, will have a favorable chance of living, it would be a mistake to sacrifice the life of the child needlessly. Since pregnancy of itself causes important changes in the human organism, a tuberculous pregnant woman should receive proportionately a greater amount of care. It is not likely, at the present time at least, that legal enactments looking to the application of any of the foregoing recommendations would be adopted or could be enforced, but these will subserve a useful educational purpose, and will receive the consideration of physicians and others interested in the welfare of the race.

Medical News.

COLORADO.

Will Establish Antitoxin Stations.—Stations for the distribution of diphtheria antitoxin are to be established by the State Board of Health in Denver and Salida.

January Deaths.—During January 915 deaths were reported in the state, an annual death rate of 18.65 per 1,000. Of these 34 were due to typhoid fever, 31 to diphtheria and 10 to scarlet fever.

Communicable Diseases.—During January there were reported to the State Board of Health, 168 cases of diphtheria, 208 of scarlet fever, 87 of smallpox, and 525 of typhoid fever. Of the latter 444 occurred in Leadville.

Obstacles to the Enforcement of Law.—John T. Bass, an osteopath of Denver, who was arrested at the instance of the State Board of Medical Examiners, charged with practicing medicine without a license, and who sued the board for $10,000 damages for malicious prosecution, was given a verdict and awarded $700 damages. The defendants will ask for a new trial.

Cause of Typhoid Epidemic at Leadville.—The typhoid fever epidemic at Leadville developed between December 20 and January 10. The State Board of Health, in its monthly bulletin, analyzes the causes of this epidemic. The diagnosis was first confirmed by two autopsies. It was found that in the fall of 1903, two cases of typhoid fever—one imported—were treated at St. Vincent's Hospital. This hospital is on some of the highest ground in the city, and the drainage is toward the center of the city. The sewage, before emptying into the sewer in the street, runs through a settling tank, where heavy matter is allowed to settle, and the liquids pass off into the sewer. This tank is made of brick and mortar, not cemented inside or out, and, consequently, is not water proof. The theory of the board as to the epidemic is as follows: Stools, which were not disinfected from these first few typhoid fever cases in the hospital, reached the settling tank, and seepage occurred downward toward the street until the water main was reached. December 5 the main was drained in the vicinity of this hospital. As soon as the mains were drained, a vacuum occurred, and, consequently, the seepage flowed into any crack in the main with which it came into contact. When the water is in the main, the pressure is so much greater inside the pipe than out that seepage can not occur. But when the main was drained the pressure was reversed. In a town like Leadville, it is not an uncommon thing, owing to the mining that is going on in the town and its vicinity, for the water mains to become injured from the settling of the ground, resulting, of course, in more or less leakage. Therefore, it was an easy matter for contaminated sewage to come in contact with one of these leaks, and for the sewage to enter the main at the time it was drained.

ILLINOIS.

Dr. Hill's Anniversary.—On March 12, Dr. William Hill, Bloomington, became 75 years old. In honor of the anniversary the older members of the profession and their wives were entertained at dinner and many useful and beautiful gifts were presented to the venerable host.

Personal.—Dr. John T. McAnally, Carbondale, who is now in Mexico, will return and resume practice April 1.——Dr. Brown Pusey, Chicago, has gone to Europe for a protracted period of study.——Dr. Charles P. Caldwell, Chicago, was severely injured, March 7, in a cable-car collision.

Communicable Diseases.—Supposed chicken-pox at Pisgah has been shown to be smallpox. There are said to be about 25 cases in 8 or 10 families.——Diphtheria has caused the mayor of Gilman to issue a proclamation closing schools and prohibiting public gatherings.——Scarlet fever is still spreading in Taylorville.

Charges Unproved.—The charges circulated against the assistant physician of Peoria County, of alleged flagrant and consistent neglect of duty, have been disproved by the county physician, who says that the trouble has arisen through a service rendered by courtesy only, and in which the judgment of a visiting nurse had been given precedence over that of a physician.

Chicago.

New Hospital for Englewood.—Rev. Bernard P. Murray of St. Bernard's Church, Englewood, has almost completed his plans for a hospital at Sixty-third Street and Harvard Avenue, to cost $200,000.

Ehrlich Coming to Chicago.—Prof. Paul Ehrlich, director of the Royal Prussian Institute of Experimental Therapeutics at Frankfort-on-the-Main, Germany, will be the representative of German medicine at the coming convocation at the University of Chicago, at which he will deliver an address, and will receive the degree of LL.D.

Will Draft New Ordinance.—A committee consisting of Drs. D. A. K. Steele, L. Blake Baldwin, A. J. Ochsner, Julius H. Hoelscher and Malcolm L. Harris, representing the various hospitals of the city, is engaged in drafting a new city hospital ordinance. The old ordinance is said to be so defective that no hospital could operate under its provisions if they were enforced.

Rules for Inspection of School Children.—Dr. Henry Hartung of the board of education has formulated the following routine for the examination of school children:

> Eyes.—Diseases of the conjunctiva and lachrymal apparatus, muscles of the eyeball, visual acuity, hypermetropia, myopia, astigmatism.
> Ears.—External ear, auditory meatus, drum membrane, hearing, acute or chronic diseases of middle ear.
> Mouth and Pharynx.—Defects of tongue, lips, palate, condition of teeth, hypertrophy of tonsils, pharyngitis, adenoids, granulations, etc.
> Nose.—Acute or chronic rhinitis, nasal hypertrophies, polypus, deflection of septum, etc.
> Chest.—Abnormal development, round shoulders, spinal deflection, diseases of the heart and lungs.
> Skin.—Acute or chronic affections, scabies. pediculosis, favus, etc.
> General Nutritional and Structural Disorders.—Anemia, chronic headaches, glandular enlargement, tuberculosis, deficiency of muscular development, nervousness, chorea, or any pathologic condition which may retard the pupil's growth or influence his progress in school work.

Erratic Mortality.—The total 549 deaths reported from all causes during the week ended March 12 are 76 fewer than those reported during the preceding week, and 82 fewer than those of the corresponding week of 1903. This, of itself, and for a single week, is not remarkable, although the annual rate, 14.75 per 1,000, is unusually low for March. One of the erratic features is the great reduction in the deaths of those over 60 years of age; the total 126 form only 23 per cent. of the total at all ages, while the average of such deaths for the previous nine weeks was 33 per cent. of the total. It might be explained that the previous rate had carried off an undue proportion of the aged; but the statement of mortality shows that chronic diseases such as consumption and cancer, whose victims are largely among the aged, caused 32 and 14 more deaths, respectively, than during the previous week. The marked and sudden increase of deaths from consumption—amounting to very nearly 40 per cent. more than the average of the previous nine weeks—coupled with a decrease of 23.5 per cent. in the deaths from pneumonia, forms another erratic feature. The 86 deaths from consumption are the greatest number ever reported in any single week, while the 127 pneumonia deaths are the fewest since the week of Dec. 26, 1903.

MARYLAND.

Personal.—Dr. J. Clement Clarke, Sykesville, has been reelected superintendent of the Springfield Hospital for the Insane.

Want Money for Asylums.—The authorities of Springfield Hospital for the Insane ask for $100,000 for buildings and $40,000 a year for maintenance. Those of Cambridge Hospital ask for $10,000 for building and $6,000 a year.

Tuberculosis Bills.—Two bills prepared by the tuberculosis commission are before the legislature. One provides for registration of tuberculous patients throughout the state; the other aims to prevent the spread of tuberculosis by requiring apartments occupied by tuberculous patients to be disinfected, and gives power to the local boards of health to do this, making it a misdemeanor for the owner to rent to other tenants without proper disinfection.

An Active Profession.—A large delegation of physicians went to Annapolis, March 8, to urge the appropriation for the new library building of the Medical and Chirurgical Faculty, but, nothwithstanding, the legislature rejected the application. With the view of discouraging any further inroads on its time the committee, through Dr. Hill, brought into the house the following order:

> Ordered that an additional room be assigned to the ways and means committee for the purpose of quarantining the letters received from the medical doctors of the state of Maryland in advocacy of a bill for the appropriation of $100.000 for a library building for the Medical and Chirurgical Faculty of Maryland. and that four stenographers and typewriters and six additional clerks be assigned to the committee, and that the postmaster be directed to deliver to the chairman of the committee $500 worth of stamps with which to answer the letters, and that a commission of attorneys

—of which Mr. George C. Morrison of Baltimore shall be chairman, at a salary of $5,000 per annum—be named by the speaker of this house to draw up the wills and settle the estates of all the members of the ways and means committee and take care of their widows and orphans, in the event of the failure of the legislature to appropriate the amount desired.

Baltimore.

Fire Alarm System in Hospital.—The Johns Hopkins Hospital has had installed a new fire-alarm system, with 13 stations and a volunteer fire department.

Personal.—Dr. St. Clair Spruill has gone to Jacksonville.——Dr. William S. Halsted will deliver the address at the next commencement of the Yale University Medical School.

Lung Disease Predominates.—While the death rate was lower 105 of the 282 deaths last week were due to affections of lungs and bronchial tubes. The rate per 1,000 for whites was 22.87; for colored, 48.29. Two cases of smallpox were reported, and there is still considerable prevalence of scarlet fever. The pneumonia deaths were 46 in number.

Bequests.—Mr. C. F. Mayer, ex-president of the B. and O. R. R., who died in Baltimore, February 24, made provision in his will for an ultimate handsome endowment fund for the Church Home and Infirmary, Baltimore.——Mr. Leopold Strouse, a Baltimore merchant, recently deceased, left $500 to the Hebrew Hospital and $2,000 to the Johns Hopkins University.

MASSACHUSETTS.

Composer's Bequests.—The will of William Francis Boott, the composer, devises $1,000 each to the Cambridge Hospital and to the Southbridge Hospital.

Made Residuary Legatee.—The Waltham City Hospital has been made the residuary legatee of the estate of Nathaniel A. Moody, which amounts to almost $28,000.

Illegal Practitioner Insane.—Ulric St. Pierre, New Bedford, who was recently fined $300 and sentenced to the house of correction, has been pronounced insane and committed to the Taunton Insane Hospital.

Fires in Hospitals.—Fire originating in an overheated furnace and appearing first in the operating room on Saturday, March 12, damaged the Melrose Hospital to the extent of $1,000. The patients were all removed safely, and are temporarily cared for in the Nurses' Home.——Fire in the Woburn Emergency Hospital, March 8, caused damage estimated at $1,000. The patients were removed in safety.

Personal.—Dr. Francis A. Bragg, Foxboro, has been nominated by the governor as medical examiner for the Sixth Norfolk district, vice Dr. J. C. Gallison, Franklin, deceased.——Dr. and Mrs. John R. Grouard, Nantucket, have sailed for Jamaica.——Dr. Forster H. Smith has been elected city physician of Lowell.——Dr. Marshall J. Mosher has been appointed physician to the Waltham Board of Health, and Drs. Edward F. Dowd, Charles A. Willis and Walter F. Adams, medical examiners of public schools.——Dr. Morton E. Cummings has been chosen as city physician of Malden, vice Dr. Richard H. Thompson.

To Avert Tetanus.—At a meeting of the Berkshire District Medical Society, February 26, the following preamble and resolution was passed:

> Whereas, Four hundred and six deaths from tetanus were reported as occurring in the United States in July, 1903, as a result of the Fourth of July celebration, 363 of these deaths having been caused by toy pistols loaded with blank cartridges, and 17 by cannon crackers.
>
> *Resolved*, That the Berkshire District Medical Society is in favor of any legislation and municipal ordinances which will effectively stop the sale and use of toy pistols, blank cartridges and cannon crackers.

Tufts College Announcements.—Tufts Medical School has increased its tuition fees from $125 to $150 a year. The following promotions and additions to the faculty are announced: Edward M. Plummer, M.D., professor of otology; Edward B. Lane, M.D., professor of mental diseases; Gardner W. Allen, M.D., assistant professor of genito-urinary surgery; Charles B. Painter, M.D., assistant professor of orthopedic surgery; John S. Ames, M.D., assistant professor of clinical medicine; Frank P. Williams, M.D., instructor in rectal diseases; Harry M. Germain, M.D., instructor in clinical surgery and assistant in anatomy; Luther G. Paul, M.D., instructor in clinical surgery; Scott McLeod, M.D., assistant in anatomy; Willis T. Middleton, M.D., assistant in anatomy; Frederick W. Stetson, M.D., assistant in clinical medicine, Arthur T. Legge, M.D., assistant in orthopedics; Leon E. White, M.D., assistant in otology; Walter E. Fernald, M.D., clinical lecturer on mental diseases; Charles M. Whitney, M.D., instructor in genito-urinary diseases, and William L. Ripley, M.D., instructor in physiology.

NEW YORK.

More Ratification.—Herkimer County Medical Society, at its annual meeting in Herkimer, March 8, passed a resolution endorsing the consolidation of the state medical society and association.

Schoolhouse for Hospital.—In Watertown, where it is said there are at least 500 cases of typhoid fever, the new high school building has been commandeered as a hospital by the board of health on the suggestion of the sanitary officer, Dr. George A. Soper, and is being used as a hospital, as the two local hospitals were overcrowded.

Insanity on the Increase.—The annual report of the state commissioner in lunacy says that 5,000 new cases developed during the year, 2,434 more than during the previous year. The total number of insane in all institutions was 25,934. There were 1,262 recoveries, a percentage of 24.72, as compared with 24.60 for the previous year.

Association to Consider Consolidation.—There will be a special meeting of the New York State Medical Association at the Academy of Medicine, New York City, March 21, to hear the report of the committee on conference of the New York State Medical Association, looking toward the union of that body and the Medical Society of the State of New York.

Personal.—Dr. Donald Ross, a member of the medical staff of the Willard State Hospital, has been appointed assistant physician to the Craig Colony for Epileptics at Sonyea.——Dr. John D. Malone, Newburgh, jumped from a trolley car while it was in motion, and sustained minor injuries. He sailed for Europe March 8.——Dr. Jesse S. Heiman won first place and Dr. Louis P. Gould second place in a competitive examination for house staff at St. Joseph's Hospital, Syracuse.

Infectious Pneumonia.—The increasing prevalence and death rate of pneumonia has been recognized by the State Health Department, which now announces that it will be given a separate column in the bulletin, instead of being grouped, as heretofore, with "acute respiratory diseases." The term "infectious" will include only the acute lobar pneumonia, and not catarrhal or broncho-pneumonia. The bulletin states that "while many prefixes to this name appear on our death returns, it is pretty safe to say that physicians generally understand the distinction as to the infectious disease we desire to specially record." The total number of deaths from pneumonia in the state during January was 1,510.

To Detect Defectives.—A state board of expert insanity experts, to be stationed at Ellis Island, to inspect immigrants as they land, with a view of detecting those in such stages of mental decline as would lead to their becoming public charges, is provided for in a bill introduced before the legislature in behalf of the State Commission in Lunacy. The total expense is estimated at not to exceed $25,000 per year, which would include one chief inspector at $5,000, two at $3,000, a male interpreter at $2,000, and a female interpreter at $1,500. The United States Marine Hospital has charge of this matter at present, but makes no provision for the employment of experts in insanity. The proposed bill is favored by Governor Odell and the lunacy commission.

Coroner's Bill Again.—Senator Elsberg has introduced his coroner's bill for greater New York, which failed to pass last year. The amended bill will allow the coroners now holding office to serve their full term, but the office will then be finally abolished. After January 1, 1905, the coroner's physicians will be transferred to a bureau of medical examiners in the department of health, in which department will be placed the jurisdiction of primarily investigating the causes of sudden and suspicious deaths in New York. From Jan. 1, 1905, to January, 1906, the latter being the expiration of the present coroner's term of office, the coroner's function will be limited to the holding of inquiries in like manner as city magistrates. After January, 1906, the coroner's office will be abolished and the medical functions will be entirely under the department of health, and the judicial functions in the hands of the city magistrates.

Buffalo.

Staff Elects Officers.—The medical staff of the Sisters of Charity Hospital elected officers as follows: President, Dr. James J. Mooney; vice-president, Dr. Charles S. Jewett, and secretary, Dr. Alfred E. Diehl.

Club Election.—The Physicians' Club, a private medical organization, has elected officers as follows: President, Dr. J. Henry Dowd; vice-president, Dr. Frederick M. Boyle, and secretary, Dr. W. K. Callahan. Resolutions were adopted recommending that an elementary course in hygiene especially pertaining to the prevention of tuberculosis be taught in the public schools.

County Hospital Report.—The annual report of the Erie County Hospital shows a total average population of 362, at an average cost of $4.59 per capita. This cost is slightly increased over the 1902 report because of the increase in coal, advance in salaries and many permanent improvements which have been made. The admissions in the different departments were as follows: Medical department, males 1049, females 344; surgical department, males 741, females 144, and gynecological and obstetrical department 118.

Superintendent for Raybrook.—Dr. John H. Pryor of Buffalo has been appointed superintendent of the New York Hospital for Tuberculosis at Raybrook in the Adirondacks. Dr. Pryor, who was the originator of a state hospital for tuberculosis, was appointed one of the trustees. In order to compete in the examination he resigned as trustee, and received the highest mark. The position pays a salary of $3,500 and maintenance, and the superintendent is privileged to have consulting practice. The hospital will be open for the reception of 100 patients June 1. Local examiners to determine eligible cases for the hospital will soon be announced.

Visitors Commend State Hospital.—The report of the board of visitors of the Buffalo State Hospital to the State Commission in Lunacy, praises the management of the hospital, and states that the hospital is not as in former years, overcrowded, the present number of patients being 1,648, with a capacity for 1,631. It speaks of the intelligence of the attendants and that patients in dress and person are clean. There is a fire drill, which is also commended. The food is of the most excellent quality. The nurses' home has been enlarged, and now is occupied by 74. Plans for a home for the superintendent are now in his hands, with instructions for the contracts. It is urgent that a separate building be constructed for the consumptive insane.

New York City.

New Sisters' Hospital.—The Sisters of the Poor of St. Francis are erecting a hospital in the Bronx, which will accommodate 350 patients.

Healer Imprisoned.—Peter Barr, self-styled "divine healer," has been sentenced to thirty days' imprisonment for practicing medicine without a license.

Prolongs Regular Session.—Long Island College Hospital announces that, as it has prolonged its regular session until June, the summer session has been discontinued.

First Aid Service in Parks.—In all the northern parks, emergency hospital tents are to be established during the spring, where the injured on the football and baseball fields and on the golf links may obtain prompt medical and surgical aid.

Cottage for Consumptives.—A cottage to be used as temporary quarters for cases of incipient tuberculosis is being erected on the lawn at Bellevue Hospital. It will contain but twelve beds, and if a greater demand is made, more cottages will be built.

Brooklyn Personals.—Drs. Elias H. Bartley and William F. Campbell have been elected trustees of the Bushwick Hospital. ——Dr. Frank A. Jennings, house surgeon of St. Catherine's Hospital, in recognition of his work during the past 15 months as house surgeon of the institution, was given a banquet by the visiting and house staffs, February 29.

Thousands for Sick Poor.—By the will of Miss Sarah Schermerhorn, $200,000 has been given to charity. Of this the mission work of Grace Church among the sick and poor receives $78,000; the general and fresh-air work of the New York Protestant Episcopal City Missionary Society, $25,000; the New York Institution for the Blind, $5,000, and the Home for Consumptives, Denver, $50,000.

New York Academy of Medicine.—A book just issued shows that there are 878 fellows, 98 associate fellows, 46 honorary fellows and 32 benefactors. The library contains over 80,000 bound volumes, about 36,000 pamphlets, and subscribes regularly to more than 1,200 current periodicals, comprising nearly all the medical journals, transactions of medical societies, hospital and boards of health reports published throughout the world.

Physicians' Building.—We are informed that a building, to be devoted to physicians' offices exclusively, at Madison Avenue and 58th Street, will be opened May 1. The owners allow a committee of lessees to pass judgment on all others who make application for suites, and the committee is making such careful selection that the experiment seems already a success. It is intended that the building shall be something in the nature of a club, with society meetings and other social features to make it attractive.

Mt. Sinai Hospital Open.—This new $3,000,000 hospital, occupying an entire block, will open its doors to the public this week. It is said to be one of the most perfectly equipped hospitals in the world; every modern scientific appliance needed has been installed, and from the basement to the roof-garden everything has been designed to make the building cheerful and comfortable. The air in the hospital is even filtered. There is an utter absence of sharp corners, or angles, thus minimizing dust accumulation and making cleaning easy. The building will house 456 patients comfortably.

PENNSYLVANIA.

Philadelphia.

Voodoo Doctor Must Hang.—George P. Hossey, the negro voodoo doctor convicted June 26, 1903, of the murder of William G. Danze, was sentenced to death by Judge Martin in the Criminal Court. Unsuccessful efforts had been made to secure a new trial.

Spitzka in Philadelphia.—On March 15, Dr. Edward C. Spitzka, New York, addressed the students of Jefferson Medical College, on "The Brain and Skull of Man and the Anthropoids." After the address he was tendered a reception by the F. X. Dercum Neurological Society at the University Club.

Friends' Asylum Resists Taxation.—The Friends' Asylum for the Insane, at Frankford, filed a bill in equity against Abington Township in order to restrain it from collecting road tax on a farm of 104 acres situated in said township. The plaintiff contends that as the institution is purely charitable, its property is exempt from taxation.

Polyclinic Hospital.—During February, 1,554 new cases were treated in the dispensaries of the Polyclinic Hospital, and 5,765 visits were paid, making a total of 7,319 cases treated in the dispensaries during the month; in the receiving ward 529 cases were treated during the same period; 83 patients were admitted to the wards of the hospital, and 93 were discharged.

New Laboratories Open in June.—The new medical laboratories of the University of Pennsylvania are to be opened June 10. The first meeting of the general committee of arrangements, of which Dr. Horatio C. Wood is chairman, has been called for March 19. It is proposed to send out more than 16,000 invitations. The American Medical Association will close its session at Atlantic City on that day, and the members will be asked to attend.

Maragliano to Address the Profession in Philadelphia.—Under the auspices of the Henry Phipps Institute, arrangements have been made with Dr. C. Maragliano, professor in the University of Genoa, and a senator in the Italian parliament, to lecture in this city, March 28, on "The Serum Treatment for Tuberculosis." Dr. Maragliano will be entertained by Dr. Flick, head of the Phipps Institute, and by other physicians. Efforts will be made to have him give one or more clinics in the hospitals of the city during his stay. He will arrive March 20.

Health Report.—Typhoid fever is still epidemic throughout the city, although there has been a decided falling off in the number of cases reported during the past week. The health authorities look for a continuance of high aggregate of cases of typhoid on account of the bad condition of the drinking water. There were 140 new cases of fever reported during the week, as compared with 195 for the previous seven days. The deaths numbered 25, an increase of 6. Smallpox broke out afresh in the early part of the week, and 48 new cases are reported, an increase of 15 over the previous week. There are now 115 smallpox patients in the Municipal Hospital, and it is estimated there are about 100 additional patients who are treated at their homes. The deaths from all causes during the week numbered 709, being an increase of 81 over those of last week, and an increase of 32 over the corresponding week of last year.

Danger Signals to City School Teachers.—On March 9, Dr. H. Augustus Wilson addressed the teachers of the public schools on "School Life and Its Relation to the Deformities of Childhood." He exhibited lantern slides showing the most common forms of deformity, many of which, he said, were due to studying in improper positions and at improperly constructed desks. He pointed out how curvature of the spine was caused by persistent faulty position in standing, sitting, sleeping and carrying heavy weights, like school books, on one side. He said that the primary inducing cause may also be due to defective vision or hearing, causing the child to keep its head in one position.

He spoke of limp as the danger signal of hidden destruction, and said it should never be disregarded He concluded by saying that whenever a child assumes persistently a faulty posture, whenever there is a limp, whenever there appears to be an increasing, languid, indolent, listless assumption of ab normal or faulty position the child should be kept under careful medical inspection

TEXAS.

State Association Meeting—The State Medical Association of Texas will hold its thirty sixth annual meeting at the University, Austin, April 26 to 29 inclusive

Hospital Dedicated—The Lawrence Johnston Clayton Emergency Hospital established by the All Saints' Hospital Association at Fort Worth, was dedicated March 7.

Donates Site for College.—Dr John O McReynolds, Dallas, has donated to the Southwestern University Medical College a plat of ground on which a medical college building will be erected

Banquet to Dr. Billings—The El Paso County Medical Society listened to an address by Dr Frank Billings, February 27, after which he was the guest of honor at a banquet given by the society

Cuspidors in Cars—The following rule, on March 31, will replace the previously existing clause in the disinfecting instructions of the state health officer, as applied to passenger coaches and sleeping cars.

> Each passenger coach or sleeping car used for passengers must be provided with one cuspidor for each two double seats, or every four chairs Each cuspidor must contain not less than six ounces of a disinfectant solution approved by this department The cuspidors to be emptied, washed in similar solution and replenished each trip or every twenty four hours

VIRGINIA.

Dr. Taylor Has Pneumonia.—Dr Hugh M Taylor is seriously ill with pleuro pneumonia at his home in Richmond He is reported to be making satisfactory progress

College Gets Appropriation—The annual appropriation of $5,000 for the Medical College of Virginia, after bitter opposition, was passed by the house of delegates, March 2

Mistrial in Unlicensed Practitioner's Case.—In the case of Mula Baksh, a "herb doctor," one of seven charged by the Norfolk Medical Association with practicing medicine without a license, the jury disagreed and was summarily discharged for the term

Would Aid Consumptives—The State Board of Health has forwarded to the legislature a report recommending the passage of a bill authorizing the governor to appoint a committee to consider the establishment of a sanitarium for consumptives, and to report to the next legislature It is stated that there are 12,000 cases in the state

County Health Report—The report of vital statistics of Elizabeth City County, prepared by the secretary to the board of health, Dr Walter Plecker, Hampton, shows a death rate for 1903, of 10 5 per 1 000 for whites, and 22 02 for colored, or 16 20 per 1,000 of all deaths Tuberculosis heads the list of death causes, closely followed by pneumonia and organic heart disease During the year 66 cases of typhoid fever, 31 of diphtheria and 6 of scarlet fever were reported

WASHINGTON.

Olympia Healthy.—The health officer of Olympia asserts that city is one of the most healthy in the United States During 1903 only 45 deaths occurred, a death rate of 6 per 1,000

Personal—Dr S B Nelson, Pullman, has been elected president, and Dr. Elmer E Heg, Seattle, re elected secretary of the State Board of Health——Dr John B Longhary has been chosen president of the Seattle Board of Health

Organization Stamps Out Smallpox—The annual report of the State Board of Health shows the benefits of organized effort in stamping out smallpox In April there were 202 cases of smallpox in the state, in May, 70, in June, 115, in July, 56, in August, 34, in September, 44, in October, 42, in November 28, and in December, 29

More Room Needed for Insane—The State Board of Control, after its February inspection, is said to have found that several of the state institutions are overcrowded, and will probably recommend an appropriation to cover the cost of additions to the state hospitals at Stellacoom, Walla Walla and Medical Lake The state has now 2,500 insane in its care, and the number is increasing rapidly

WISCONSIN.

Must Take Rest.—On advice of his physician, Dr. William H Earles, Milwaukee, will go to Southern California to regain his health, which has been impaired by overwork

State Board Moves—On and after April 1, the office of the secretary of the State Board of Health will be in Madison, and all communications intended for the board should be addressed to Dr Cornelius A. Harper, secretary, Madison, Wis

County Asylum Burned—Racine County Insane Asylum at Gatliff was burned to the ground, February 22 All the patients, numbering 133, were brought out in safety and taken to Racine The loss is $115,000, half of which is covered by insurance

A Good Law if Enforced.—The Milwaukee City Council, on March 7, passed an ordinance prohibiting spitting on the floors of public buildings, sidewalks and public vehicles, and providing a fine of $5, or ten days' imprisonment for conviction of violation of the ordinance.

Dr. Wingate Resumes Practice— Dr. U O B Wingate, Milwaukee, who for ten years has filled most admirably and ably the position of secretary of the State Board of Health, announces that on his retirement from that position, April 1, he will devote his time and attention entirely to medical practice

GENERAL.

Indians Have Smallpox.—The Indians in the Northwest of Canada are suffering from an epidemic of smallpox

First Aid in Pennsylvania Railway.—Plans have been approved by officials of the Pennsylvania Railway to place medical outfits, with stretchers, in stations and on trains, to be of service in case of accidents First aid instruction will be given the employes

Famous Foreigners at Atlantic City Session—Dr A Lorenz has announced his intention of being present at the next session of the American Medical Association at Atlantic City, June 7 to 10 He will come to Philadelphia as the guest of Dr. H Augustus Wilson about May 25 At the commencement exercises of the Jefferson Medical College, May 27, he will have conferred on him the honorary degree of LL D Dr Albert J Hoffa, professor in the University of Berlin, and Dr. Lorenz will hold an orthopedic clinic at the college, Monday morning, June 6, from 9 30 to 12.30 Arrangements are under way by which perhaps other eminent men from across the water will be present

FOREIGN.

Cancer Research in Greece—Question blanks were distributed to the physicians throughout Greece, and every one of the blanks was filled out and returned The total 56 physicians had only 7 cases of cancer to report in a population of 66,000 The stomach, uterus, tongue and breast were the organs affected

Radiology.—We notice that the *Riforma Medica*—which attempts to classify its abstracts—has now one department devoted to "Radiology" Works on radioactive substances and phototherapy in general are included under this title, which has supplanted the former heading of "Sensational Medicine" The sensation of yesterday is the work field of to day.

Vienna Anglo-Americans Organize—To further the interests of American physicians studying in Vienna, the Anglo American Medical Association was organized, February 22, with a membership of 68 The following officers were elected: Dr Amond Ravold, St Louis, president, Dr Ralph P Daniells, Chicago, vice president, and Dr F G Harris, Chicago, secretary and treasurer

Another Appeal for Brevity—This time it is the dignified *Deutsches Archiv f Klinische Medicin* which states that it has tried to keep pace with the constantly accumulating material by issuing its numbers at shorter intervals This increases the cost to both publishers and subscribers, while long articles drag through several numbers, and readers lose their interest From every point of view, therefore, it is advisable to reduce the amount of material The editors beseech all intending to contribute to its columns to condense their articles as much as possible They hint that the length of an article is liable to be in inverse proportion to the age and experience of the writer

Battle of the Clubs in Germany.—The demands of the medical officers of the sickness insurance societies for increased remuneration now that their term of service has been doubled by recent legislation, have been unexpectedly re enforced on the floor of the Prussian house of deputies by the minister of the interior department, who censured the lawmakers for ignoring the medical officers of the societies in this legislation. The organized stand taken by the profession in the matter has led to contention between the medical and the financial officers of the societies, and these words of a member of the Prussian cabinet are regarded as an indication that the government will sustain the profession in their moderate demands.

Sweden to Have a Medical Weekly.—Dr. K. Kjellberg of Stockholm has commenced the publication of a weekly medical journal, to be the official organ for the General Swedish Medical Association. The title is *Almänna Svenska Läkartidningen.* The first two numbers have been received and contain instructive articles on "Arrhenius and the Doctrine of Immunity"—a subject discussed editorially in these columns, page 651—and others on Finsen treatment of lupus, paraffin prothesis, etc. The list of collaborators on the journal includes Profs. E. Almqvist, J. Borelius, H. Köster and seventeen others. The journal *Eira* was previously the organ of this association, but it suspended publication on the death of its editor, Dr. Simon, last June.

The Age Limit for Professors in the French Universities.—"Few die and none resign" seems to apply to university professors as well as elsewhere. A Paris exchange gives a list of 17 professors who served until they died at 83, 86 or even at 92, all over 71. Eight professors resigned at the age of 72 to 82. These, with other data which it presents show that the imposition of an age limit was a wise measure. The limit was at first 70 and was then reduced to 55 and 60. The students' mode of protesting against the recent abolition of the age limit is not parliamentary, but as the *Gaz. Méd. de Paris* remarks, "it takes a small revolution to accomplish anything at Paris." The rioting has gradually subsided after a week or two of interference with the lectures. The students have organized and presented a petition to the authorities begging to have the age limit of 70 years restored.

Fifteenth International Medical Congress, Lisbon, 1906.—The first article of the official regulations for this congress establishes the date as April 19 to 26, 1906. The second article refers to membership, which is limited: 1, to physicians applying, and 2, to scientists, who shall be presented by the Portuguese executive committee or by the national committees of other lands. French is to be the official language for international relations, the committees setting aside their own language, the Portuguese, completely. In the general assemblies and section meetings English, French and German may be employed, and in the section meetings other languages may be used, provided the communication is followed at once by the same translated by some member into one of the languages permitted. All communications destined for the congress should be sent to the secretary general, Professor [illegible] Lisbon, before Jan. 1, 1906. They should be accompanied by a summary, which will be published and distributed to the members of the corresponding section by the congress authorities. Communications may be sent in later, but will then have to await their turn after those already on the order of the day have been disposed of. The subscription fee is $5, which can be paid to the treasurer, Prof. Alfredo Lopes of Lisbon, or to the national committee in each country.

Professor D'Antona's Acquittal.—Professor D'Antona of Naples is one of the leading surgeons of Italy and one of the most respected and beloved. He was made the defendant in a sensational suit under the following circumstances: He performed an exploratory laparotomy on a patient in the last stages of a liver affection. The conditions were found inoperable, as the family had been warned might be the case, and the abdomen was closed, leaving two hemostatic forceps and gauze tampons. The following day he removed the forceps and some of the gauze strips, and then, as usual, left the further care of the case to the surgical personnel of the Pace Hospital. The gauze tampons were renewed several times, and the family, profiting by the temporary improvement in the condition after the laparotomy, removed the patient from Naples to Campobasso, where he died three days after his arrival. The necropsy revealed an ascitic-purulent accumulation at the inner end of the gauze. The family instituted criminal proceedings against Professor D'Antona, accusing him of "homicide from imprudence." The committee of six medical experts testifying in the case included Foa, Bassini and Novara, and their report was to the effect that the condition of the patient was so precarious that the leaving of the gauze in the abdomen was most certainly not the cause of the fatal termination, and that it was very doubtful whether it had hastened it. The case was appealed from court to court, but the supreme court has finally fully exonerated Professor D'Antona, who received an ovation from his friends and students when he returned to Naples, February 15. The final trial was before the senate of the realm, which resolved itself into the supreme tribunal for the purpose, as Professor D'Antona is a senator. Seventy witnesses were examined.

Anti-quack Legislation in Baden.—The various states of Germany leave much to the discretion of the local authorities in the matter of repressing quackery. Baden has now taken the lead in more drastic measures, and the Landtag is now considering a bill, endorsed by the government, which provides for a fine of $40 or imprisonment for charlatans whose practices conflict with the interests of public health or morality or with the decrees issued to protect the populace against swindling. The same penalty is imposed for publicly announcing or advertising misleading notices in regard to competency, special training or successes or making exaggerated promises or proposing to treat patients without a personal examination (absent treatment). The same penalty is imposed likewise for announcing or advertising drugs whose free sale is prohibited or means for preventing conception. These regulations do not apply to announcements in the medical press. Dr. Julian Marcuse of Mannheim writes to the *Berliner klinische Wochenschrift* that the new bill realizes several of the wishes of the profession, which the authorities have always declared impracticable. The bill makes the editors of journals also responsible for publishing extravagant ads, and it puts an end to the distributing of circulars, pamphlets, etc., by quacks. The market-crier style of advertising is forbidden both for quacks and for registered physicians. Marcuse finds nothing to criticise in the entire bill except the reference to means to prevent conception, which he thinks had better be omitted. In all other respects the bill is a model which he hopes will find imitation elsewhere. Its passage in the Landtag seems to be assured. It is pointed out that when it is legally forbidden to advertise in true charlatan style and distant treatment is also forbidden under penalty, the circles in the populace who pin their faith to what they read in print—and these circles are larger than is generally recognized—will be protected against injury to health and life as well as pocket.

DUBLIN LETTER.

Amalgamation of Hospitals.

An interesting event took place here lately in the completion of the scheme for the amalgamation of the ophthalmic hospitals. For the past twenty years it has been proposed that St. Mark's Ophthalmic Hospital and the National Eye and Ear Hospital should join their resources to form one large and efficient institution. After much opposition the outlines of the arrangement were agreed to, and in 1896 a great bazaar was held to provide funds to build an entirely new hospital. Since then, though still working as separate branches, the two old hospitals have had their management in common, but within the last few weeks the new building has been finished, and the patients have been transferred to it. The result will be that more work can be done in better surroundings, with much greater economy. It is a pity that some of the other Dublin hospitals do not follow the example set them by the ophthalmic hospitals, a course recommended twenty years ago by a viceregal commission; for a more wasteful system than the present one can not devise. In a city of about quarter of a million inhabitants there are no less than ten general clinical hospitals. The largest of these contains about three hundred and fifty beds, but most of them have only a hundred or less. Each of them is overstaffed, but as the medical attendants are none of them paid, this may not be a disadvantage. Indeed, as long as good men are to be had, and the medical profession of Dublin stands very high, it is no harm to keep many men attached to a hospital. But the expenses of management are enormously increased by the multiplicity of institutions, and students are unable to see a great variety of cases. It must be remembered, however, that none of the hospitals possesses medical schools, the schools being separate educational institutions. Outside pressure has frequently been brought to bear on the hospital authorities to persuade them to amalgamate some of the smaller institutions, but conservatism and vested interests have kept the day.

Royal Academy of Medicine.

The Royal Academy of Medicine has just published its proceedings for 1903—a volume which is supposed to represent the scientific work of the profession in Ireland. Though it contains many interesting contributions on clinical cases, on the whole it is a disappointing collection. Each physician is content to furnish a description of his case, but the whole volume does not contain what can be called a complete article. The references to literature are most meager, and the whole tone is lamentably insular. Things have sadly changed since the days when Dublin physicians—Graves, Stokes, and their contemporaries—wrote in such a way as to make the Dublin school famous throughout the world, not only for clinical acumen, but for broad scholarship and classical style of literary composition. Nowadays we look to your side of the seas for medical men who can write sound and clear English, and we take our models in Wendell Holmes, Weir Mitchell and Osler.

Pollution of Shellfish by Sewage.

A valuable research into the conditions of the oyster-beds and other shellfish layings on the Irish coast has just been made by the officers of the local government board. The object of the inquiry was to discover to what degree the various layings were liable to sewage contamination, and two series of investigations were made. An inspector, Dr. Brown, made a topical examination of the various localities, and noted the nearest points of sewage outfall, and of discharge of surface drainage. His opinions constitute one part of the report, while the second part consists of the investigations of the board's bacteriologist, Dr. McWeeney, into the condition of shellfish sent him from each bed by the inspector. Each gentleman formed his conclusions independently of the other, and a comparison of the two reports is consequently very interesting. The bacteriologist takes as his standard of purity the absence of *B. coli* and *B. enteritidis sporogenes*, although recognizing that the habitat of these germs in nature is still doubtful. The test is in all probability somewhat rigorous, and should not be considered final for practical purposes, unless borne out by local examination. In every case in which the inspector believed contamination either probable or possible, Dr. McWeeney found evidence of fecal pollution, although in some the number of organisms present was very small. The result as a whole shows that at the present time the majority of Irish beds are in an unsanitary condition, some of them, as, for instance, all those in Dublin Bay, being positively bathed in sewage. On the other hand, there are many beds, particularly on the west coast, absolutely free from all possibility of contamination, and as there is unlimited expanse of pure seaboard still available the industry should not eventually suffer.

LONDON LETTER.

Striking Success of the Anti-Malarial Expedition to Ismailia.

Sir Alfred Jones, the munificent patron of the Liverpool School of Tropical Medicine, entertained a company of merchants and scientists to meet Professor Boyce on his return from Egypt and to receive his report on the anti-malarial expedition to Ismailia. The results are striking. When Major Ross visited Ismailia in September, 1902, there were 2,000 cases of malaria annually in a population of 9,000, of whom 2,000 were Europeans. The authorities carried out Major Ross' suggestions as to filling up marsh land and clearing out small irrigating channels and stagnant waters, at an expense of $22,000. They organized a drains brigade and a petroleum brigade. As a result people can now sleep in any of the European quarters without mosquito nets. The annual number of cases of malaria was reduced to 200. No fresh cases occurred, and there were no deaths in the year among Europeans, and only four among natives, against 30 deaths the year before. So great was the improvement that Prince d'Arenberg, president of the Suez Canal Company, hoped before two years to see Ismailia regarded as a sanatorium and watering-place for Cairo. Tropical medicine is showing that we have been for centuries cultivating medicine applicable to our own country and domestic life and neglecting our great empire all over the world. The time has come when medicine applicable to the whole world must be taught. Major Ross said that the success of the anti-malarial campaign at Ismailia had taught two things—that a large town could be entirely rid of mosquitoes and that it was equally possible to eradicate malaria. He has been asked by the government to draw up a report on malaria in India, where among the troops and the gaol prisoners 300,000 cases are admitted to hospital per annum. With the results obtained in Ismailia before him he is confident that this immense admission rate can be reduced to one-third.

Ambidexterity.

A society for the promotion of ambidexterity has been formed under the name of "The Ambidextral Culture Society." The list of members contains some prominent names in medicine, and among the laity, such as Mr. Noble Smith, the orthopedic surgeon, Sir James Sawyer, Lady Florence Dixie, and the professors of natural history at the universities of Edinburgh and St. Andrews. Among the subjects on the syllabus for discussion are "Ambidexterity in the Infant School," "Physiology of Simultaneous Ambidextral Work," "Ambidexterity in Angling," and "Ambidexterity from the Medical Point of View."

The Cambridge Diploma in Tropical Medicine.

The great advances recently made in tropical medicine, as previously stated in The Journal, have led to the establishment of a diploma in that subject by the University of Cambridge. In Germany and France military, naval and colonial physicians are required to attend courses in tropical medicine before taking up their duties. There are indications that similar regulations will soon be applied to physicians desiring to enter the British service abroad or to engage in medical missionary work. In a recent colonial office circular it is proposed that colonial government physicians shall pass an examination to obtain a certificate of efficiency in tropical medicine. The government has encouraged Cambridge University to institute a test in the knowledge of tropical diseases. The examination will be held once a year. As evidence of study and attainments candidates may present records of work done in tropical medicine and any diploma of public health or sanitary science. Such evidence will be considered as a qualification for admission to the examination, and will also count in the examination. The examination will comprise: 1. Methods of pathologic and bacteriologic investigation, examination of the blood. The characters, diagnosis and life history of animal and vegetable parasites. The examination, chemical and microscopic, of poisonous or contaminated foods and waters. 2. The origin, pathology, propagation, distribution, prevention, symptoms, diagnosis and treatment of the epidemic, endemic and other diseases of tropical climates, including malarial fever, blackwater fever, trypanosomiasis, relapsing fever, dengue, yellow fever, plague, tetanus, beri-beri, dysentery and hepatic abscess, cholera, enteric fever, Malta fever, specific diarrheal affections of the tropics, disease due to cestodes and other worms, filariasis, bilharzial disease, specific boils, sores and other cutaneous affections, mycetoma, ophthalmic affections of the tropics, affections caused by poisonous plants and animals and by poisoned weapons, and sunstroke. 3. The general effects on health in the tropics of seasons and climate, soil, water and food. Personal hygiene, acclimatization. Principles of general hygiene, with special reference to food and water supplies, sites, dwellings, drainage, and the disposal of refuse. The sanitation of native quarters, camps, plantations, factories, hospitals, and asylums, gaols, pilgrim and coolie ships. Principles and methods of disinfection. Each candidate must pay a fee of $35 before admission or readmission to examination.

Benzine in Coal Gas.

In a paper read at the Royal Society Dr. R. Staehelin stated that when frogs are exposed to coal gas motor phenomena are produced which are absent if the gas is previously purified by passage through oil and that these phenomena can be reproduced if the purified gas is made to take up benzine vapor. The investigation had its origin in a paper by Vahlen, who maintained that coal gas and carbon monoxid differed in poisonous action and that the former produced in frogs excitatory phenomena which were absent in animals exposed to the latter. In warm-blooded animals this difference was not observed. Benzine administered to rabbits and guinea-pigs by inhalation appears to produce no effect. This tends to show that in man benzine plays no part in coal-gas poisoning. However, benzine vapor is described by Mr. Wynter Blyth, the toxicologist, as producing tinnitus, convulsive trembling, twitching of the muscles and dyspnea.

Correspondence.

The Patenting of Surgical Instruments.

Denver, Colo., March 11, 1904.

To the Editor:—At the present time medical ethics prevent the best men in medicine from patenting various appurtenances which their brains, experience and philanthropy may have caused them to bring into existence. Such a generous stand is evidently taken in order that humanity in general, and the medical profession in particuar, may be benefited thereby; in fact, the motives are too obvious to require discussion. In other words, a man of medical genius is supposed to give freely of the fruits of his labor, and suffering mankind is supposed to be the recipient. Why, then, is it that physicians are shortsighted, careless and improvident as to overlook the fact that their gifts never reach those for whom they were intended?

The above may seem a broad statement, but it is nevertheless true, and should be given consideration. For instance, take any of the various instruments that have been introduced into surgery in the last few years and let us run over approximately their usual history. The inventor, usually a man of experience and brains, after much thought and trouble evolves in his mind a method whereby some pathologic condition may be rendered more amenable to treatment. To carry out his idea he designs a new instrument and consults some local instrument maker, in order to test his theory. After a trial or two, and probably considerable expense, the instrument maker accomplishes his object, and the instrument is produced according to the author's idea.

Then, after a few months' use, the inventor finds his object accomplished, and next negotiates with the manufacturer. The mercantile gentleman just alluded to at once procures a patent, and straightway raises the price to any figure that may suit him; and what is the result? Where is the public? How about a brother practitioner? Where is the philanthropy? And what is the outcome of this benevolent and misguided ruling of medical ethics? Simply this: The price of the article is just as high as if the inventor had procured the patent and received the profits himself.

Better no ethics at all than the present methods. since then, at least, the man who deserves the credit—the inventor—would be benefited.

I do not pretend to be a reformer, but I would rather respect established customs when possible, yet the question here arises: Can not these matters be rendered more consistent? Would it not be better to have these articles patented by medical men, and thus control the market? Or, if ethics would not trust the inventor thus far, would it not be better to establish a national committee to hold such patents and look after the production of such instruments, maintaining the standard of quality and holding the prices down to a reasonable figure? The organization could probably be made self-sustaining by the exaction of small royalties, and prosecutions of infringements carried on by funds thus derived.

More difficult matters than these have been overcome and regulated; why not, then, these also?

M. E. Preston.

Hospital Experience Necessary for Licensure.

Loring, La., March 10, 1904.

To the Editor:—In The Journal, March 5, Dr. Lawrence Holmes of Asheville, N. C., advocates the rejection, by statutory law, of all candidates for licensure who have not had one year of interneship in a good hospital. No one will deny that a year in a good hospital would be of incalculable value to the prospective physician; but there are various reasons why this is not practicable. Internes must generally bear their own expenses, as no compensation is provided. None but the wealthy, or sons of the wealthy, could avail themselves of this privilege under these conditions. This would make of the medical profession a privileged class, much as the officers of the English army, whose incompetence some say is notorious.

I think that the statement that "internes are composed of the best class of students" is not true.

The hospital-trained student would not be so practical a man for the rural district, other things being equal, as the one not so trained. The country physician, miles from assistance, in the cabin or shack, comes face to face with situations and emergencies which he must handle alone, and which your hospital interne, with his ideas of trained nurses, assistants, etc., could never pass through successfully.

Your correspondent cites the case of the young man who was ignorant regarding syringomyelia, and yet this ignorant young man was allowed to practice on an innocent and unsuspecting public. Now, with all due respect to Dr. Holmes, I would like to ask if he ever diagnosed, absolutely and positively, a case of syringomyelia, except on the postmortem table.

In "Diseases of the Nervous System," by Hirt, on page 471, is the following: "The practical significance of these (postmortem) abnormalities is not great, as, for one thing, the signs during life are so uncertain and changeable that a correct diagnosis has almost to be regarded as accidental; and secondly, because the disease, even if recognized, is not at all accessible to any treatment." Does that look as if the man who was ignorant of syringomyelia was so grossly incompetent, when the expert acknowledges that he can not recognize the disease and can not treat it, if by accident he happens to make a correct diagnosis?

By all means, let us have a uniform and reasonable standard of qualifications for entrance to the medical profession. But, in my opinion, it only hinders reform to make ridiculous proposals.

F. C. Bennett, M.D.

Eyestrain as a Cause of Headache and Other Nervous Symptoms—A Question of Precedence.

Philadelphia, March 12, 1904.

To the Editor:—Concerning the courteous note of Dr. A. L. Ranney, under the above heading in The Journal March 12, kindly permit me a few words of reply. I am conversant with the literature to which Dr. Ranney points, and it has always given me pleasure to emphasize the discoveries in medical science made by Americans.

To Dr. Stevens and to Dr. Ranney credit is due for the first, continuous and indefatigable advocacy of the rôle of heterophoria in causing eyestrain and its reflexes. But my contention is a very different one. I believe that heterophoria has no influence or but little in causing eyestrain or the reflex ocular neuroses under discussion. In my writings, I have persistently advocated the view that tenotomy is not only unnecessary, but is really a prevention of cure. To me heterophoria is one of the results of eyestrain, and what success I have had in stopping the eyestrain reflexes and results of eyestrain has been gained without a single tenotomy. Moreover, I feel convinced that this error in the treatment of heterophoria by tenotomy in directing attention to an effect instead of to the cause of eyestrain, has had the most pernicious of consequences. In the minds of the large majority of the American medical profession tenotomy has proved to be without curative effect on the systemic reflexes of eye strain, and in the disappointment at the failure and continued overemphasis of this theory, the true theory of the cause in ametropia and of the real cure by scientific lenses, has been overwhelmed in undeserved, indiscriminate and unscientific opprobrium. I could demonstrate this by any number of quotations from reviews, editorials, etc., from medical journals. In my sketch of "The History of Migraine," etc., I was interested only in what I think the line of progress—the main or trunk line—and not in an unused switch which runs to a deserted mining camp. The article of Martin, to which I alluded, contended that migraine was due to astigmatism, heterophoria not being mentioned. Martin's article was the first clear statement with which I am acquainted of the truth that migraine is due to ametropia. Personally I do not altogether agree with Martin as to some details, but I think his contribution is an epoch-making one, and in the line of definite and continuous progress.

Geo. M. Gould.

Membership in the Approaching International Medical Congress.

[Translation.]

Lisbon, Feb. 24, 1904.

To the Editor:—In No. 5 of The Journal (Jan. 30, 1904), I read under the heading "Admission to International Congresses" a notice to the effect that the national committee for Great Britain had adopted a resolution that the membership of international medical congresses shall in future be limited to physicians, and that this resolution was forwarded to the executive committee of the approaching International Medical Congress at Lisbon.

Allow me to inform you that no resolution of this kind has been received by the executive committee of the congress, and that the Article 2 of the Regulations, which restricts to physicians alone admittance as members to the congress, was drawn up by the executive committee last June, and was unanimously adopted by the committee of organization and publicity at its meeting in October, 1903.

It is, therefore, exclusively to *these committees* that the honor (if honor it be) is due of having restored to the international medical congresses the exclusively medical character which they had always maintained until the Madrid Congress.

I may be permitted to add that the president of the national committee for Great Britain received a copy of the regulations of the congress in December, 1903, and formally congratulated the executive committee on the form given to the article in question.

I shall be much obliged if in an early number of The Journal you will correct in accordance with the facts the notice to which this explanation refers.

Miguel Bombarda, Secretary General.

Hôpital de Rilhafolles.

[The committees of the congress are to be congratulated on taking this wise action, before they received any official request so to do.—Ed.]

A Study of a Case of Green Urine.

Jackson, La., March 8, 1904.

To the Editor:—Apropos of the article of Dr. Cooper with the above title, in The Journal March 5, page 638, is the following case: While an interne of the Charity Hospital, New Orleans, during 1901, I was called about 2 o'clock one morning to a patient suffering from urinary retention. I found a young negro man with a greatly distended bladder. He was easily catheterized, and an unusually large quantity of urine of a beautiful light-green color was withdrawn. He informed me that he had been taking some pills which he had purchased at a nearby drug store, and which had been recommended to him by the druggist for the cure of "lost manhood." He showed me several of the pills, together with the vial containing them. They were coated with some white substance, and the essential substance was in appearance not unlike methylene blue. The directions were one three times daily. Apparently they were prepared by the local druggist. The druggist had told the man to watch the color of the urine for evidence of the proper effect of the medicine. The patient had been passing green urine for several days before retention took place, and up to that time he was very much elated over what the pills were doing for him. There was no appreciable stricture, nor had he suffered from retention before, according to his statement. It occurred to me at the time that the drug ingested, either through the medium of the urine or by its systemic effects, had caused the retention. There were no other apparent effects, except the psychic, before the man learned better. Unfortunately neither the urine nor pills were carefully examined.

E. M. Hummel, M.D.

The Circulating Medical Article.

Chicago, March 14, 1904.

To the Editor:—Apropos of your editorial on "The Circulating Medical Article" (The Journal, March 12, 1904, p. 716), the following letter from Professor Finsen is of interest. It is in reply to a letter from me calling attention to the way in which his name and the reputation of his institute are being misused in this country:

Kopenhagen, Feb. 2, 1904.

Professor Dr. Wm. Allen Pusey.

Dear Sir:—Thanking you for your letter, I can not but highly regret the abuse which is made of my name. I have not the least to do with the matter, which you speak of in your letter, and there are nowhere "branches" of the Finsen Light Institute, consequently in America neither.

On the other hand, I am hospitable to all physicians, ... but as you understand it is impossible to me to control the people and to know whether they are going to abuse my name later on or not.

My name is also highly abused here in Europe, but I have been obliged quite to give up to take the matter into my hands, as it would cost too much time and pain, and yet be of very little use.

With my best thanks, Yours faithfully, Niels R. Finsen.

It must take a good many Christian virtues to be a scientist like Finsen, and to not be a misanthrope.

W. A. Pusey.

A Disclaimer.

Richmond, Va., March 14, 1904.

To the Editor:—It has just come to our notice that one J. Sills Daniels, M.D., of this city, the proprietor of a so-called cancer-cure sanitarium, and sanitarium for the treatment of diseases of women, especially obstetric cases, an asylum for the unfortunate, etc., who also offers a diploma as a member of the hospital staff for a consideration to any physician desiring it, has without our knowledge or authority, announced us as consulting physicians of the said sanitarium. We desire to stamp such a statement as a piece of unwarranted impertinence, and absolutely without any foundation in truth.

Signed: J. N. Upshur, M.D.,
Jacob Michaux, M.D.
Landon B. Edwards, M.D.,
Ramon D. Garcin, M.D.,
B. L. Taliaferro, M.D.

Queries and Minor Notes.

Anonymous Communications will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

CHARGES FOR SERVICES TO PHYSICIANS AND THEIR FAMILIES.

Denver, March 10, 1904.

To the Editor:—In The Journal, March 5, there appears a communication from Dr. B. P. Anderson of Colorado Springs, relative to a bill rendered him for professional services to his daughter by a physician residing in New York City. From the evidence presented it would appear that our New York friend is engaged in "small business," under the circumstances in which the bill was presented to Dr. Anderson. Dr. Anderson, however, in alluding to the incident, deals with this misguided physician in a most lenient and gentlemanly manner, as he fails to either mention his name or give his address. As a matter of reference to other members of the profession I would suggest that the name and address of this man be published in the columns of The Journal. The medical profession is filled with men of big hearts, men who stand true to the ideals of the framers of the Principles of Ethics, men who *cheerfully respond day or night to the calls of their colleagues* and their families with never a thought of remuneration. The conduct of this physician who attended a member of Dr. Anderson's family must be condemned by all decent men in the profession.

Clarence L. Wheaton, M.D.

632 Seventeenth St.

New York City, March 8, 1904.

To the Editor:—Under the above caption Dr. B. P. Anderson asks for information and quotes an instance in The Journal, March 5, 1904. The question is one to which some of us have to give pretty serious consideration, and perhaps it would be well to have the question discussed with reference to personal experience, as the matter is one *that can not be* covered in all of its features by the Principles of Ethics. There are no doubt some consultants whose entire time could be devoted to physicians and their families. Personally, I find that, averaging by the year, one-tenth of my work is for physicians. When I am so busy that it becomes necessary to charge physicians for operative work or *for consultation I shall* have so much money that it will not be necessary to charge physicians for operative work or for consultation. There is, however, a side feature requiring consideration, and that is time loss for out-of-town work. This means a direct and immediate loss of money, and it has been necessary to make the same charge to physicians that would be made to laymen for time. I do not want pay for work, and, *in fact, feel* uncomfortable if a physician feels that he ought to make me a present. Most of us, I am sure, consider it a privilege and a pleasure to help out a colleague who is in trouble. On the other hand, in choosing a physician for my own family it was stipulated that he should charge full fees for visits, on the ground that it left us free to call him in whenever we wanted him, and often when he would know that there was no real necessity for calling. There is a good deal of comfort that is worth all that it costs in feeling free to call in the physician whenever he is wanted, and not when he wants to come, and under such circumstances he should receive proper compensation. Robert T. Morris.

58 West 56th St.

Note.—Apropos to the above we quote the following from the Principles of Ethics: "Compensation for expenses. When a physician is summoned from a distance to the bedside of a colleague in easy financial circumstances, a compensation, proportionate to traveling expenses and the pecuniary loss entailed by absence from the accustomed field of professional labor, should be made by the patient or relatives."

ADHESIONS BETWEEN UTERUS AND RETAINED FETUS.

Clifty, Ky., March 2, 1904.

To the Editor:—Recently there came under my observation a case in which there were adhesions between the fetus and upper cervical wall of the uterus; the adhesions corresponding to a point about the seventh cervical vertebra and a little below the internal os. This woman carried the child twelve months. When I saw her the membranes had been ruptured and the occiput was under the pubic arch. She never knew of any water escaping from her. Now I am unable to find in my text books anything that proves my observation. Playfair cites the three celebrated cases of Drs. Oldham, Simpson and Cheston; in one case the child remained in uterus fifty-two years without decomposition, and in another the fetus wore out a hole through the uterine wall and gut, but he fails to state whether adhesions caused that or not. I believe the condition I have outlined is possible, since we know that ulcerations and wounds can affect the fetus without destroying its life, and we also know that ulcerations and ruptures of the membranes do occur without expelling the contents of the uterus, hence the possibility of two raw surfaces coming together and adhesion resulting. Is there a case on record which shows the possibility of such condition? If not, what is your opinion?

H. A. Elkomis.

Answer.—The report of this case is extremely unsatisfactory. Was the child living or dead? If alive, of course there must be some mistake about its having been carried twelve months. If dead, it was a case of missed labor. What was its condition? Was there a beginning lithopedion formation or a calcareous degeneration? Then the exact history of the pregnancy should have been given and the phenomena that probably occurred at the end of nine months or at the death of the child. The history of the termination of labor and final result should also be given. In cases of missed labor or missed abortion, that is, in retention of a dead fetus in the uterus, petrifying infiltration frequently occurs. Deposits are made in the membranes, the skin of the fetus and in the uterine decidua. In this way extensive adhesions may eventually form between the fetus and the uterus. Without further data to judge from, it seems probable that the adhesion found in the case reported was produced in this way. It was therefore the result of the retention of the fetus and not the cause, as seems to have been assumed by our correspondent.

PNEUMONIA MORTALITY.

Fort Smith, Ark., March 8, 1904.

To the Editor:—Will you please give me the death rate from pneumonia according to the Census of the United States for the year 1900? Will you also tell me where to find the death rate from this disease in New York, Chicago and Boston during the last twenty years? Are there any statistics to prove that the death rate from pneumonia has been increasing during the past ten years?

James A. Foltz.

Answer.—According to the U. S. Census the death rate per 10,000 in 1890 was 186.9, and for 1900, 192. This applies to the registration area which includes the New England states, New York, New Jersey, the District of Columbia and a few others. The best way to obtain the death rate in the larger cities would be to write direct to the departments of health, who could give the desired information. Nearly all the statistics of the cities in the northern part of the country show a decided increase in pneumonia in the last ten years. It, however, commenced before that time in many parts, in Chicago, for example. We think the municipal health departments and the secretaries of the boards of health of the different states would afford the best information in this regard. In many of the states there is no accurate registration, but in the larger cities a record of the deaths from all causes is being kept.

DISAPPEARANCE OF SYMPTOMS OF URETHRAL STRICTURE OF FOURTEEN YEARS' DURATION AFTER A SINGLE SOUNDING.

B. T. Simpson, Buffalo, N. Y., sends us a report of a patient [illegible] had specific urethritis at 18, and five months later [illegible]ine diminished in size and force. The difficulty increased with years, so that he consulted Dr. Simpson, who passed a *bougie à boule*, size 12 French, without detecting any stricture. There was, however, some difficulty in passing the sphincter muscle. He then introduced successively steel sounds, Nos. 16, 20, 24 and 26, without difficulty. All symptoms disappeared and the patient could pass his urine freely and with considerable force. Nine months later there had been no recurrence of any of the symptoms. Dr. Simpson considers the case one of spasmodic stricture. This case is not extremely rare, but the length of time during which the case remained without relief is unusual.

BOOKS ON CLIMATOLOGY.

———, March 12, 1904.

To the Editor:—Can you give me the names and publishers of late works on climatology, including that of the seacoast? Not too voluminous.

P. A. W.

Answer.—Large works on therapeutics like that edited by Solis-Cohen contain more or less thorough memoirs on the climatology from a medical point of view. (This volume was reviewed in The Journal, June 21, 1902, p. 1638.) For a general statement of the facts on climatology as a science perhaps one of the best works is the "Handbook of Climatology," by Dr. Hann (Professor Ward's translation), published by Macmillan & Co., price $3.00 net. It is not strictly a medical book, but its medical bearings are easily picked out in the text. It is a good work for the general reader and especially for the physician.

RIGHT TO PRACTICE—TEMPORARY ABSENCE FROM A STATE.

Guantanamo, Cuba, March 1, 1904.

To the Editor:—Please inform me whether one holding a certificate to practice medicine in Missouri, obtained in 1901, before the new act went into effect, and who then came into the service of the United States, is eligible to return and take up a practice, or is his certificate null after a certain length of time? It was registered with a county clerk in December, 1902. Will you give me the names of the secretaries of the boards of Missouri and Michigan?

E. G. B.

Answer.—The certificate is not nullified by absence. The secretary of the Missouri board is Dr. Winn F. Morrow, Kansas City; of the Michigan board, Dr. B. D. Harison, Sault Ste. Marie.

THE DEATH OF DR. ROBERT D. MURRAY.

More than one correspondent has expressed surprise at having seen no notice in The Journal of the death of Dr. Robert D. Murray, whom they consider as certainly worthy of mention. Dr. Murray died Nov. 22, 1903, and a notice of his death appeared in The Journal, Nov. 28, 1903, six days later.

Marriages.

Robert B. Spalding, M.D., Clinton, Ill., to Miss Nanna M. Scott, at Selma, Cal., March 6.

Charles Edward Wright, M.D., to Miss Katrina Fertig, both of Indianapolis, March 1.

Charles E. Cord, M.D., Chicago Heights, Ill., to Mrs. Laura Beeler of Chicago, February 27.

Lorin C. Collins, M.D., Chicago, to Miss Anna R. Fan Stoff Lindblad, at Wheaton, Ill., March 10.

L. Lenton Culp, M.D., Little Eagle, S. D., to Miss Blanche Cornelius of Columbia City, Ind., Oct. 8, 1903.

Bruce Anderson, M.D., Paris, Ky., to Miss Chorine Kern of Bourbon County, Ky., at Lexington, Ky., March 8.

McMillan Rowley, M.D., Downey, Cal., to Miss Bessie Sutton of Denver, at Los Angeles, Cal., February 19.

R. Elmore Rowland, M.D., Eldorado, Ark., to Miss Georgia Henry of Lancaster, Ky., at Little Rock, Ark., February 25.

George Kapelle de Kapelle, M.D., Mount Vernon, N. Y., to Miss Jane L. Sturtevant of New York City, at New Rochelle, N. Y., February 27.

D. I. Askren, M.D., formerly of Mount Ayr, Iowa, but now a medical missionary at Medinet-el-Fayoum, Egypt, to Miss Alice B. Underwood, at Assiout, Egypt, February 10.

Deaths.

Ralph Schuyler Goodwin, M.D. College of Physicians and Surgeons, New York, 1866, some-time president of the Connecticut Medical Society, and of the Litchfield County Medical

Society; for sixteen years a member of the State Board of Health; member of the American Academy of Medicine and American Public Health Association; health officer of Thomaston, Conn., died at his home in that place, March 5, from Bright's disease, after an illness of one month, aged 64.

William J. McDermott, M.D. New York University, 1854, surgeon in the Civil War, who was with Colonel Ellsworth when he was shot at Alexandria, Va., aided in the amputation of the arm of Gen. O. O. Howard, and was a prisoner in Libby Prison; a personal friend of Presidents Lincoln and Grant, died at his home in New York City, March 12, after a lingering illness, aged 73.

Justin G. Thompson, M.D. University of Michigan, Ann Arbor, 1861, a surgeon in the Army during the Civil War; formerly president of the Erie County Medical Society, and for many years local surgeon of the Lake Shore and Michigan Southern Railway, died at his home in Angola, N. Y., March 6.

Peter Gourdin de Saussure, M.D. Medical College of the State of South Carolina, Charleston, 1878; a member of the American Medical Association, professor of obstetrics, gynecology and diseases of children in his alma mater, died at Riverside Infirmary, Charleston, S. C., from pneumonia, March 8, aged 46.

John Frank Geis, M.D. Medical College of Indiana, Indianapolis, 1891, professor of chemistry, toxicology and forensic medicine in the Medical College of Indiana; deputy coroner of Marion County, died at his home in Indianapolis, March 7, from pneumonia, after a short illness, aged 35.

Anton F. Blocki, M.D. Rush Medical College, Chicago, 1892, a member of the American Medical Association, and health officer of Sheboygan, Wis., died at his home in that place, from acute disease of the liver, for which operation was unsuccessfully made, March 6, aged 37.

Philip H. Brothers, M.D. Jacksonville Medical College, 1853, a member of the American Medical Association, and once a member of the legislature from Calhoun County, died suddenly in a field near his home in Zula, Ala., from heart disease, March 4, aged 74.

Charles H. Richmond, M.D. University of Buffalo, 1860, president of the village of Livonia, N. Y., for ten years, died from the effects of bichlorid of mercury, given by mistake for the mild chlorid, after an illness of six days, March 2, aged 63.

Robert Saunders Henry, M.D. University of Maryland, Baltimore, 1883, a graduate of the U. S. Naval Academy, Annapolis, Md., died at his home in Charleston, W. Va., March 10, from nephritis, after an illness of a year, aged 52.

John Orlando Scott, M.D. University of Louisville, 1862, of Sherman, Texas, surgeon in the Confederate service during the Civil War, died at St. Vincent's Sanitarium, Sherman, after a surgical operation, March 8, aged 66.

Ida R. Gridley-Case, M.D. College of Physicians and Surgeons, Boston, 1889, a member of the American Medical Association, died from pneumonia, March 9, after a short illness, at her home in Collinsville, Conn., aged 41.

Stanley G. Clarke, M.D. New York University, 1868, for a time a member of the board of health and president of the Central Hospital, Brooklyn, died at his home in that city from diabetes, March 5, aged 61.

Oliver W. Lindsay, M.D. Ohio Medical University, Columbus, 1896, coroner of Franklin County, Ohio, formerly secretary to the superintendent of health of Columbus, died at his home in Columbus, March 8, aged 29.

Verranus Morse, M.D. New York University, 1849, one of the founders of the Young Men's Christian Association, died at his home in Brooklyn, March 9, two days after a fall, in which he fractured his hip, aged 85.

Daniel Baert, M.D., for 43 years a practitioner of Zeeland, Mich., for 11 years president of the village, died at his home in that place, March 7, from paralysis, after an illness of several weeks, aged 64.

Charles T. Whybrew, M.D. College of Physicians and Surgeons, New York, 1870, died at his home in New York City, March 8, from Bright's disease, after an illness of several weeks, aged 62.

John S. Witcher, Jr., M.D. Kentucky School of Medicine, Louisville, 1891, of Salt Lake City, Utah, died at Holy Cross Hospital in that city, March 4, from gastric fever, aged 36.

James Billingslea, M.D. University of Maryland, 1878, of Baltimore, died at Harrietstown, N. Y., March 2, aged 46.

August F. Reinhold, M.D. University of Berlin, Germany, 1876, of New York City, died in San Francisco, March 3.

Richard Huggins, M.D. Louisville National Medical College, 1894, died at his home in New Albany, Ind., March 6, from double pneumonia, after an illness of one week, aged 46.

Henry Albert Rundlett, M.D. Harvard University Medical School, Boston, 1887, died at his home in New York City, March 8, from pneumonia, after a brief illness, aged 47.

George A. Traylor, M.D. University of Tennessee, Nashville, 1882, of Bryantsville, Ky., died suddenly from apoplexy while making a professional call in Lancaster, Ky., aged 71.

David H. Poyneer, M.D. Fort Wayne (Ind.) College of Medicine, 1880, died at his home in Pomery, Wash., February 20, from heart disease, after an illness of about a year.

Lorenzo D. McLean, M.D. New York University, 1866, died at his home in East Glastonbury, Conn., March 3, from pneumonia, after an illness of four days, aged 69.

Emory Potter, M.D. Hygeio-Therapeutic College of New York, 1860, died at his home in Saratoga Springs, N. Y., from organic heart disease, February 27, aged 72.

Samuel G. Dilburn, M.D. Medical College of Alabama, Mobile, 1890, of Braggs, Ala., was run over by a train at Wallace, and instantly killed, March 7.

George S. Storm, M.D. Homeopathic Hospital College, Cleveland, 1877, died at his home in Willoughby, Ohio, March 8, after an illness of one week, aged 48.

J. Milton Bowers, M.D. Bennett College of Eclectic Medicine and Surgery, Chicago, 1871, of San Francisco, died at San Jose, Cal., March 7, from paralysis.

Edward Down, M.D. Penn Medical University, Philadelphia, 1865, died at his residence in Kensington, Philadelphia, from Bright's disease, March 11, aged 65.

Israel P. Wilson, M.D. Keokuk Medical College, a dentist of Burlington, Iowa, died suddenly at his home in that city, from heart disease, March 9, aged 67.

Giles W. Van Vleck, M.D. Homeopathic Medical College, Philadelphia, 1852, died at his home in Jackson, Mich., March 4, after an illness of three weeks.

Aaron B. Robbins, M.D. University of Denver, 1885, died at his home in Denver, March 10, from paralysis, after a long period of invalidism, aged 79.

Moses D. Knight, M.D. University of Pennsylvania, Philadelphia, 1861, died at his home in Clinton, N. J., March 6, from heart disease, aged 70.

Pliny P. Gordon, M.D. University of Buffalo, 1865, of Hobart, Ind., died, March 9, at Ridgeland, Miss., where he had gone for his health, aged 68.

James B. Townsend, M.D. University of Nashville, 1869, died at his home in Montgomery, Ala., February 29, after an illness of two years, aged 68.

S. Alex Smith, M.D. Atlanta (Ga.) Medical College, 1891, died at his home in Thomasville, Ga., March 8, after a lingering illness, aged 37.

Romulus C. Biggs, M.D. Bellevue Hospital Medical College, New York, 1868, died at Portsmouth, Ohio, March 3, from typhoid fever.

Fred Mannhardt, M.D. Universities of Tübingen and Heidelberg, Germany, 1843, died at his home in Galion, Ohio, March 4, aged 87.

James D. Beck, M.D. Tulane University, New Orleans, 1870, died at his home in Mason, Texas, January 25, from Bright's disease.

James M. Saunders, M.D. Hahnemann Medical College, Chicago, 1871, died at his home in Dodge Center, Minn., January 23.

James D. Smallhorn, M.D. Trinity College, Dublin, Ireland, died from heart disease at his home in Buffalo, February 24, aged 63.

Frederick B. Jackman, M.D. University of Maryland, Baltimore, 1880, died recently at his home in Clinton, Conn.

W. C. Riley, M.D. University of Missouri, St. Louis, 1852, died at his home in Houstonia, Mo., March 7, aged 88.

Louis Turner, M.D. American Medical College, St. Louis, Mo., 1874, died at his home in St. Louis, March 5, aged 72.

Lawrence Hesselroth, M.D., surgeon in the U. S. Navy during the Civil War, died recently at his home in Chicago.

David D. Toal, M.D. New York University, 1867, died at his home in New York City, February 26, aged 66.

Augustus W. Munson, M.D. Cleveland Medical College, 1854, a retired physician of Kenton, Ohio, died recently.

Theodore F. Holmes, M.D. Indiana, 1897, died at his home in Pickard, Ind., March 6, from pneumonia, aged 60.

Franklin S. Douglass, M.D. Medical College of Georgia, Augusta, 1883, of Scranton, Pa., died recently.

George F. Bradbury, M.D. Tulane University, New Orleans, La., 1878, died suddenly at Modesto, Cal.

George W. Neville, M.D., died at his home in Bethel, Kan., February 21, from paralysis, aged 81.

M. C. Wilkinson, M.D., died at his home in Quitman, Ga., February 28.

Deaths Abroad.

A. A. Liebeault, M.D., the founder of the Nancy School of hypnotism died there February 18, aged 81. His attention was attracted to hypnotism by witnessing a subject bleed at the nose when ordered to do so during his sleep. As a pioneer he opened a clinic at Nancy for gratuitous treatment of ailments by suggestion. He was regarded as a charlatan and impostor until in 1881 Bernheim and others became convinced and joined his standard. Institutes for psychotherapy now exist in many places. One recently founded at Amsterdam is named for him, and his pupils gathered in 1902 to place a tablet on the house at Favières where he was born seventy-nine years before.

Jose Calvo y Martin, M.D., formerly professor of anatomy at Madrid and senator of Spain, died at Madrid, February 8, aged 90. In spite of his advanced age he still took an active interest in affairs, and only the week before his death was prominent in endorsing the child labor bill presented to the Spanish parliament by Dr. Tolosa Latour.

Magnus G. Blix, M.D., professor of physiology at Lund, Sweden, died there, February 14, aged 54. He was noted as an original investigator in the physiology of the muscles and special senses, and inventor of a number of instruments for use in physiologic research.

H. Emminghaus, M.D., professor of psychiatry at Freiburg until six months ago, died there, February 16, aged 68. He had served in a similar capacity at Würzburg and later at the Russian university at Dorpat. He has written numerous works on his specialty.

Book Notices.

A Text-Book of Operative Surgery. Covering the Surgical Anatomy and Operative Technic Involved in the Operations of General Surgery. Written for Students and Practitioners. By Warren Stone Bickham, Phar.M., M.D., Assistant Instructor in Operative Surgery, College of Physicians and Surgeons, New York. With 559 Illustrations, Entirely Original. Cloth. Pp. 984. Price, $6.00 net. Philadelphia, New York, London: W. B. Saunders & Co. 1903.

The author has devoted an unusual amount of space to the descriptive and surgical anatomy of the structures involved. This is perhaps of more use to the student in the dissecting room than to the surgeon in the operating room. About 140 pages are devoted to the arteries and veins, part of which is a rather needless elaboration. Under directions for differentiating arteries from veins it is stated in favor of arteries, "their thinner walls," under veins, "by having thinner coats." Should a vein be wounded when removing lymphatic glands from the neck, the author says: "If so situated (i. e., the wound in the vein) that closure can not be immediately made, the part should be flooded with water so that water stands over the open vein, to prevent the drawing in of air until the vein can be secured." It would be hard to conceive of anything that would make the discovery and control of a bleeding vein more difficult than to have the field flooded with water and blood. Under operations on the gasserian ganglion and its branches we find no mention of Cushing's method of approach, nor of Abbe's operation. Enucleation operations for tumors of the thyroid are also wanting. Under trephining the author states: "It is probably best to open the dura in all cases of trephining." This is not the rule of experienced surgeons. The dura should not be opened unless some indication exists for so doing, for in many cases of fractures extradural hemorrhages, osteomyelitis, etc., the dura is not injured, and to open it would be entirely unnecessary and but increase the risks of infection. Most of the illustrations are new and well executed, but Figure 158 shows a front view of the lower end of the femur on a side view of the leg, and Figure 207 shows the excision of a tendon sheath from the extensor tendon of a finger where no tendon sheath exists. The technic of the various operations is well described, but where more than one method of operating is given there are no rules to aid an inexperienced operator in making a selection. Advice in this direction would have added materially to the value of the work. So far as the mechanical part of operating goes the work covers the ground very well.

The American Year-Book of Medicine and Surgery for 1904. A Yearly Digest of Scientific Progress and Authoritative Opinion in All Branches of Medicine and Surgery, Drawn from Journals, Monographs and Text-Books of the Leading American and Foreign Authors and Investigators. Arranged, with Critical Editorial Comments, by Eminent American Specialists, Under the Editorial Charge of George M. Gould, A.M., M.D. In Two Volumes. Volume I, Including General Medicine. Pp. 673. Fully Illustrated; Volume II, General Surgery. Pp. 680. Fully Illustrated. Cloth. Price, per volume, $3.00 net. Philadelphia, New York, London: W. B. Saunders & Co. 1904.

These two volumes keep up the reputation of this annual that it has well deserved in the past. In a work like this it is necessary to cull from an immense amount of medical literature, and the ability to do this and to properly collate the important facts that are most worthy of note is not common, but Dr. Gould evidently has been able to command such ability. The names of the editors, including those of Drs. Chalmers DaCosta, Barton Cooke Hirst, W. A. Newman Dorland, V. P. Gibney, Walter L. Pyle and others in surgery; of Drs. Abbott, Church, Edsall, Crozer Griffith, A. O. J. Kelly, Riesman, Stengel and others in medicine, are sufficient evidence of the value and thoroughness of the work. It is one of the best periodical medical summaries that is available to medical readers in any English-speaking country. The two volumes make a total of over 1,200 pages of solid valuable matter.

A Reference Handbook of the Medical Sciences, Embracing the Entire Range of Scientific and Practical Medicine and Allied Science. By Various Writers. A New Edition. Completely Revised and Rewritten. Edited by Albert H. Buck, M.D., New York City. Volume VII. Illustrated by Chromo-lithographs and 688 Half-tone and Wood Engravings. Cloth. Pp. 951. Price, $7.00 per volume. New York: Wm. Wood & Co. 1904.

This volume, the last but one of the complete Reference Handbook, covers subjects from saccharin to ulcer. Beside an enormous number of more or less short articles, there are included in this volume many exhaustive ones, so exhaustive that they may be called complete monographs. Among these may be mentioned those on scarlet fever, occupying 22 pages; the sexual organs, 47 pages; the spinal cord and its diseases, 115 pages; the stomach and its diseases, 68 pages; syphilis, 32 pages; teratology, 50 pages; tuberculosis, 16 pages, and typhoid fever, 12 pages. These articles, as well as the shorter ones, are as a rule written by those who are specialists in the subjects treated, and consequently are scientific and reliable. Since all subjects are brought well up to date, most of the articles have had to be rewritten in part; not a few of the subjects are entirely new. The work is proving to be one of the most complete and satisfactory cyclopedias of medicine that is to be had in any language.

Bacteria, Yeasts and Molds in the Home. By H. W. Conn, Ph.D., Professor of Biology in Wesleyan University, Middletown, Conn. Cloth. Pp. 293. Price, $1.00. Boston and London: Ginn & Co. 1903.

Professor Conn is well known as well fitted to furnish a popular work on such a subject. He has brought together an amount of information which will be of value to the general public. The work is destined, he says, for all who are interested in household affairs, or who have the practical charge of homes and are interested in keeping them in good healthful conditions; we do not know any other work that could be better recommended for the ground covered. A little knowledge is sometimes a dangerous thing, but the facts given here are not so little as to prove perilous, and may be of decided value in correcting bad practices and misapprehension on the part of those who have charge of the health essentials of our daily life. It is popularly written and will be of interest to any general reader. The illustrations are numerous and good.

The Practical Care of the Baby. By Theron Wendell Kilmer, M.D., Associate Professor of Diseases of Children in the New York School for Clinical Medicine. Cloth. 12mo. Pages xiv-158, with 68 Illustrations. Price, $1.00 net, delivered. Philadelphia: F. A. Davis Company.

The author's object was to give, in rather more detail than is usual in works of this kind, the principal points that the mother or nurse should know in regard to the care of the child in its earliest months of life. With this in mind, Kilmer has included many illustrations as to the proper methods of holding the infant, etc., and these are a valuable addition. A diet schedule and a brief account of the disorders to which they are liable is added in the latter part of the book. The advice, of course, is not for home treatment, for the physician is almost universally recommended to be called in, but the recognition of the conditions is often very important. The book will be a very useful one for the inexperienced mother or nurse.

Subjective Sensations of Sight and Sound. Abiotrophy and Other Lectures. By Sir William R. Gowers, M.D., F.R.C.P., F.R.S., Hon. Fellow R. Coll. Phys., Ireland. Cloth. Pp. 250. Price, $2.00. Philadelphia: P. Blakiston's Son & Co. 1904.

Among the English neurologists Sir William R. Gowers stands practically at the head, not only for his ability and contributions, but for his long and wide experience. In this little volume are included a number of lectures, which have appeared in print at various times in the past. They have been revised for the present publication. Their value was recognized as they appeared in the medical journals from time to time, and their collection in a book form is a convenience to the general reader, few of whom have had the opportunity to read all the originals, appearing as they did, some in the British medical weeklies, and some in the German journals and elsewhere.

The Complete Medical Pocket-Formulary and Physician's Vade-Mecum: Containing Upwards of 2,500 Prescriptions, Collected from the Practice of Physicians and Surgeons of Experience, American and Foreign. Arranged for Ready Reference Under an Alphabetical List of Diseases. Also a Special list of New Drugs, with Their Dosage, Solubilities and Therapeutic Applications; Together with a Table of Formulæ for Suppositories; a Table of Formulæ for Hypodermic Medication; a List of Drugs for Inhalation; a Table of Poisons, with Their Antidotes; a Posological Table; a List of Incompatibles; a Table of Metric Equivalents; a Brief Account of External Antipyretics; Disinfectants; Medical Thermometry; the Urinary Tests; and Much Other Useful Information. Collated for the Use of Practitioners. By J. C. Wilson, A.M., M.D., Physician to the German Hospital, Philadelphia. Third Revised Edition. Leather. Pp. 268. Price, $1.75; Thumb Index, $2.00. Philadelphia: J. B. Lippincott Co.

The title of this little work gives a fair idea of its contents. It will undoubtedly prove useful to many physicians. though like every other formulary only as an adjunct to original prescribing.

Diseases of the Nervous System. A Text-book for Students and Practitioners of Medicine. By H. Oppenheim, Professor of the University of Berlin. Translated and Edited by Edward E. Mayer, A.M., M.D., Pittsburg, Pa. Second American Edition, Revised and Enlarged. With 343 Illustrations. Cloth. Pp. 953. Price, $5.00 net. Philadelphia and London: J. B. Lippincott Co. 1904.

This second American edition of Oppenheim's work will be received with the favor that attended its predecessor. The new matter introduced by Professor Oppenheim in his third German edition has been translated and inserted, and the translator and editor has also added here and there some further data that have been obtained since the revision of the last German edition. Attention is called to the fact that Professor Oppenheim has incorporated in this work observations never published elsewhere, which gives the work an added value as an original source of information.

The Self-Cure of Consumption Without Medicine, with a Chapter on the Prevention of Consumption and Other Diseases. By Charles H. Stanley Davis, M.D., Ph.D., Member of the Connecticut State Medical Society. Cloth. Pp. 176. Price, 75 cents. New York: E. B. Treat & Co. 1904.

This is one of the many semi-popular works that are appearing, and will probably continue to appear, in regard to the disease which is exciting so much popular attention at the present time. The author has brought together a valuable amount of instruction which the average consumptives or those who have charge of them, can receive with profit. In one place we notice what seems to us a slight tendency to fadism as regards diet, but such blemishes are few, and the work as a whole can be safely recommended.

Manual of Practical Anatomy. By D. J. Cunningham, M.D. Edin. et Dubl., D.Sc., LLD., D.C.L. Oxon., F.R.S., Professor of Anatomy in the University of Edinburg. Volume I: Upper Limb. Lower Limb. Abdomen. Volume II: Thorax, Head and Neck. Third Edition. Illustrated. Cloth. Pp. 605 and 607 Respectively. Price. $5.00. Philadelphia: J. B. Lippincott Company. 1903.

This manual of practical anatomy appears in this edition in the form of a series of volumes, the first on the upper and lower extremities and abdomen, and the second on the thorax, head and neck. The illustrations are a valuable addition for the understanding of the descriptions. It is one of the most convenient and best anatomic manuals that we have seen, certainly one of the most up to date, which is of some importance.

Manual of Medicine. By Thomas Kirkpatrick Monro, M.A., M.D., Fellow of and Examiner to the Faculty of Physicians and Surgeons, Glasgow. Cloth. Pp. 901. Price, $5.00 net. Philadelphia and New York: W. B. Saunders & Co.

This book is not elaborate enough for a work on practice—that is to say, one that completely meets the needs of the practitioner; it is one that will be useful to the medical student, or to one who desires to brush up. Within its limitations it is generally admirable.

Miscellany.

The True Physician.—Methods of conduct are of just importance; business methods are of just importance, and while it is impossible, perhaps, to make a gentleman out of a rogue, yet every physician must know the principles of conduct, and know them well. There is needed the spirit of a gentleman, a scholar and a good citizen to make the true physician.—*Medical Fortnightly.*

Streptococcus Serum in Infections.—A. Hirsch has been much impressed with the value of antistreptococcus serum in the treatment of streptococcus infections. He describes, in the *St. Petersburg. med. Wochenschrift*, Vol. 28, No. 44, 1903, a small epidemic of scarlet fever in which the effect of the serum was unmistakable. He warns that the drop in the temperature is not enough to determine whether the initial dose has been adequate. The heart, pulse, respiration and general condition must be taken into account besides. He thinks that there is a field of usefulness for these injections in mixed infection with tuberculosis when streptococci are numerous in the sputa.

One Sort of Saving.—Dr. Cyrus Edson of New York, who had a large income from his practice, left a personal estate of only $4,000. His widow explains that Dr. Edson's charity was as large as his professional ability and his capacity for work. No one, however poor, would be turned away without advice, as Dr. Edson was always ready to give them the benefit of his professional skill. Several years ago a citizen of Baltimore, who had given much to charity, failed in business. One of his friends, in talking over the situation, asked him if he did not feel *now that* misfortune had overtaken him, that he had made a mistake, giving away so much. "Mistake?" he asked, with a show of surprise. "Bless your soul, that is all I have saved out of the wreck." The above is from the *Waterbury (Conn.) Republican.* Charity should be freely exercised, but the failure to secure payment from those who could pay at least a small fee is not charity, but sin—injuring the physician, the patient, the profession and the public.

Intoxication with Laundry Bluing.—A. Kramer of Dorpat relates, in the *St. Petersburg med. Woch.*, that he was summoned to a child in convulsions with mydriasis and pulse and respiration growing constantly fainter and more irregular until the latter ceased completely. The child had eaten two balls of laundry bluing three hours before. Not knowing the composition of the bluing he was at a loss what to do. He could only proceed symptomatically, and succeeded in reviving the patient with artificial respiration, brandy and milk per os and per rectum and wine of antimony. The child gave the first signs of spontaneous movements after three hours of these efforts, after which he rapidly recuperated, and by the next morning was apparently quite well, except for some loss of appetite, explainable by the amount of alcohol taken. Study of the laundry blue showed that it was composed of ultramarine, and that the ingredients of the latter are kaolin, soda, sulphur and carbon or similar substances which generate sulphuretted hydrogen in the presence of an acid or acid salts. The intoxication was, therefore, due to H_2S. It must have been absorbed from the stomach into the blood, but did not cause any toxic action on account of the alkalinity of the blood, until it reached the lungs, where it probably became free again and exerted its specific action. As a proportion of .02 per cent. of H_2S in the air has a toxic effect, the symptoms observed are easily explained, also the long latency before they developed. Cahn has reported a case in which a student intoxicated with sulphuretted hydrogen in the morning did not develop symptoms until late in the afternoon.

Diabetes from Fright.—A. Lorand of Carlsbad has observed 2 cases of fatal diabetes occurring in previously healthy young women consecutive to a severe fright. (*St. Petersburg. med. Wochenschrift*, Vol. 28, No. 22, 1903.) In the first case the young woman while bicycling narrowly escaped being run down by a trolley car. She felt that "her heart stood still," but was able to pedal home. She felt exhausted the next day, and by the fifth, thirst and polyuria attracted attention, and in two or three weeks 7 per cent. sugar was discovered in the urine. By the fifth month symptoms of severe diabetes had become established, somewhat improved by a stay at Carlsbad, but then continuing a progressive course with death in about a year after the fright. The second patient was a robust girl of 16, who was attacked by a man in a dark street on her way home from school. She escaped unharmed, and fled into the house near by. The next day she noticed that her mouth was very dry and that she felt exhausted. This was followed by symptoms of dyspepsia and gradual emaciation for six months before any one thought of examining her urine. Sugar was found in the proportion of 8 per cent., and a course at Carlsbad also improved the symptoms in this case, but terminal coma developed not long afterward. The urine had never been examined in these cases before the fright, and the diabetes may possibly have previously existed. The unwavering good health, however, speaks against this assumption.

The Public Service.

Army Changes.

Memorandum of changes of station and duties of medical officers of the Army for the week ending March 12, 1904:

Woodson, Robert S., asst.-surgeon, so much of paragraph 1, S. O., as granted two months' leave, amended to read one month, with permission to apply for thirty days' extension.

Torney, George H., deputy surgeon general, left from duty as chief surgeon, Department of California, en route to take command of U. S. Army General Hospital, Presidio of San Francisco.

Maus, Louis M., deputy surgeon general, granted thirty days' sick leave to take effect on the arrival of Captain Elmer A. Dean at Fort Riley, Kan.

Girard, Alfred C., asst.-surgeon general, announced as chief surgeon, Department of California, San Francisco.

Kulp, John S., asst. surgeon, relieved from duty as attending surgeon and examiner of recruits, Philadelphia, and ordered to Fort McDowell, Cal.

Dean, Elmer A., asst.-surgeon, leave extended fourteen days.

Mabry, William C., contract surgeon, granted an eight days' extension of his leave of absence from the Department of the Lakes.

Navy Changes.

Changes in the medical corps of the Navy, week ending March 12, 1904:

Thompson, E., P. A. surgeon, detached from the Marine Detachment, Culebra, W. I., and ordered to the *Des Moines*.

Furlong, F. M., P. A. surgeon, detached from Naval Station, Guantanamo, Cuba, and ordered to the Marine Detachment, Culebra.

Orvis, R. T., P. A. surgeon, detached from the Marine Department, Culebra, and ordered to Naval Hospital, New York.

Angney, G. L., P. A. surgeon, detached from Panama Marine Brigade, and ordered to the Naval Station, Guantanamo.

Richardson, R. R., as[illegible] detached from the *Amphitrite* and ordered to Naval I[illegible] Fla.

Stepp, J., asst.-surgeo[illegible] the Navy Yard, Boston, Mass., and ordered to th[illegible]orarily, and then return to duty at the Boston Navy Yard.

Spratling, L. W., surgeon, detached from the Bureau of Medicine and Surgery and ordered to the Marine Battalion, on the Isthmus of Panama.

Marine-Hospital Service.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service, for the seven days ended March 3, 1904:

Nydegger, J. A., P. A. surgeon, granted leave of absence for one month from March 6, 1904, on account of sickness.

McMullen, John, P. A. surgeon, bureau order of Dec. 3, 1903, relieving P. A. Surgeon McMullen from duty at Hongkong, China, and directing him to proceed to San Francisco, amended so that he shall report to the chief quarantine officer at Honolulu for temporary duty.

Fricks, L. D., P. A. surgeon, relieved from duty at the Immigration Depot, New York City, and assigned to duty in the office of the United States Consul at LaGuayra, Venezuela.

Goldberger, Jos., and Korn, W. A., asst.-surgeons, to report to chairman of board of examiners at Washington, D. C., March 9, 1904, for examination to determine their fitness for promotion to the grade of P. A. surgeon.

Holt, J. M., asst.-surgeon, to proceed to San Francisco.

Trotter, F. E., asst.-surgeon, relieved from duty at San Francisco and directed to report to P. A. Surgeon Rupert Blue, Plague Laboratory, San Francisco, for duty.

Lloyd, B. J., asst.-surgeon, relieved from duty at San Francisco and assigned to duty in the office of the United States Consul at Callao, Peru, Feb. 26, 1904, to proceed to Concord, Cal., for special temporary duty March 1, 1904.

Boggess, J. S., asst.-surgeon, granted leave of absence for three days from February 18.

Warren, B. S., asst.-surgeon, granted one day's extension of leave of absence Feb. 22, 1904.

Manning, H. M., asst.-surgeon, relieved from duty at Honolulu, T. H., and directed to proceed to Manila, P. I., and report to chief quarantine officer for assignment to duty.

Ashford, F. A., asst.-surgeon, granted leave of absence for ten days from March 28.

Richardson, S. W., pharmacist, to proceed to St. Louis and assume charge of the Marine-Hospital exhibit at the Louisiana Purchase Exposition.

PROMOTION.

Perry, J. C., P. A. surgeon, commissioned as surgeon.

BOARDS CONVENED.

Board convened at Washington, D. C., Feb. 29, 1904, for the physical examination of candidates for position of second assistant engineer, Revenue-Cutter Service. Detail for the board: Asst.-Surgeon-General L. L. Williams, chairman; Asst.-surgeon A. J. McLaughlin, recorder.

Board convened at Washington, D. C., March 4, 1904, for the physical examination of Chief Engineer G. B. Maher, Revenue-Cutter Service. Detail for the board: Asst-Surgeon-General L. L. Williams, chairman; Asst.-Surgeon-General W. J. Pettus, recorder.

CASUALTY.

Russell, Howard C., asst.-surgeon, died at Stapleton, N. Y., March 2, 1904.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the period from March 6 to March 12, 1904:

SMALLPOX—UNITED STATES.

California: Escondido, Feb. 23-March 3, 1 case.

District of Columbia: Washington, Feb. 27-March 5, 6 cases.

Florida: Jacksonville, Feb. 27-March 5, 7 cases.

Illinois: Feb. 27-March 5, Chicago, 4 cases; Danville, 1 case; Springfield, Feb. 25-March 3, 3 cases.

Louisiana: New Orleans, Feb. 25-March 3, 7 cases imported.

Michigan: Detroit, Feb. 27-March 5, 1 case; 88 localities, Feb. 20-27, present.

Missouri: St. Louis, Feb. 27-March 5, 13 cases.

New Hampshir[illegible] 27-March 5, 7 cases, 1 death.

New Jersey: F[illegible] den, 2 cases; Trenton, 1 case.

New York: Fe[illegible] alo, 1 case; New York City, 1 case; Niagara [illegible] 5, 2 cases.

North Carolina: Wilmington, March 1-8, 3 cases.

Ohio: Cleveland, Feb. 26-March 4, 1 case; Dayton, Feb. 27-March 5, 19 cases, 2 deaths.

Pennsylvania: Altoona, Feb. 24-March 5, 1 case imported; Carbondale, Feb. 29-March 7, 1 case; Feb. 27-March 5, Johnstown, [illegible] cases, 6 deaths; Pittsburg, 4 cases.

[illegible] Feb. 20-27, 2 cases.

[illegible] 5, Memphis, 36 cases, 2 deaths; Nash-

[illegible]

Wisconsin: Milwaukee, Feb. 27-March 5, 4 cases.

SMALLPOX—INSULAR.

Porto Rico: San Juan, March 8, 6 cases.

SMALLPOX—FOREIGN.

Austria: Prague, Feb. 13 20, 3 cases.

Belgium: Antwerp, Feb. 13-20, 6 cases, 1 death.

Brazil: Pernambuco, Jan. 16-31, 28 deaths; Rio de Janeiro, Jan. 31-Feb. 7, 37 cases, 27 deaths.

Canada: Quebec, Feb. 27-March 5, 3 cases.

China: Chefoo, Feb. 6, present; Shanghai, Jan. 16-30, 3 cases, 37 deaths.

France: Feb. 6-13, Lyons, 1 death; Paris, 36 cases, 1 death.

Great Britain: Feb. 12-26, Edinburgh, 12 cases, 1 death; Glasgow, 51 cases, 3 deaths; Leeds, Feb. 20-27, 1 case; Feb. 13 20, London, 9 cases; Manchester, 1 case, 1 death; Nottingham, Feb. 6-20, 35 cases, 1 death.

India: Bombay, Feb. 2-9, 8 deaths; Calcutta, Jan. 30-Feb. 6, 2 deaths; Karachi, Jan. 31-Feb. 7, 4 cases.

Java: Batavia, Jan. 23-30 16 cases, 2 deaths.

Malta: Feb. 6-13, 1 death.

Mexico: City of Mexico, Feb. 21-28, 5 cases, 4 deaths.

Russia: Feb. 6-13, Moscow, 5 cases, 2 deaths; St. Petersburg, 3 cases, 1 death.

Spain: Santander, Feb. 21-28, 4 cases, 1 death.

Turkey: Constantinople, Feb. 14-21, 4 deaths; Smyrna, Jan. 31-Feb. 7, 1 case.

Venezuela: Maracaibo, Feb. 7-14, 1 case, 1 death.

YELLOW FEVER.

Brazil: Rio de Janeiro, Jan. 31-Feb. 7, 4 cases, 3 deaths.

Mexico: Merida, Feb. 21-27, 2 cases: Vera Cruz, Feb. 20-27, 1 case.

CHOLERA—INSULAR.

Philippine Islands: Jan. 23-30, Manila, 1 case, 1 death; Provinces, 120 cases, 90 deaths.

CHOLERA—FOREIGN.

India: Calcutta, Jan. 31-Feb. 6, 14 deaths.

PLAGUE—INSULAR.

Hawaii: Hilo, March 4, 1 death.

Philippine Islands: Manila, Jan. 16-Feb. 30, 5 cases, 3 deaths.

PLAGUE—FOREIGN.

Africa: Port Elizabeth, Jan. 8-16, 2 cases.

Brazil: Pindamonhangaba, Jan. 15, several cases; Rio de Janeiro, Jan. 31-Feb. 7, 7 cases, 4 deaths.

India: Bombay, Jan. 2-9, 419 deaths; Calcutta, Jan. 30-Feb. 6, 50 deaths; Karachi, Jan. 31-Feb. 7, 49 cases, 37 deaths.

Medical Organization.

Arkansas.

EIGHTH COUNCILOR DISTRICT MEDICAL SOCIETY.—This society was organized at Little Rock, February 24, and elected the following officers: President, Dr. George S. Brown, Conway; vice-president, Dr. Strodder U. King, Little Rock, and secretary, Dr. William C. Dunaway, Little Rock. The meeting was followed by a banquet, over which the vice-president presided as toastmaster.

Indiana.

FLOYD COUNTY MEDICAL SOCIETY.—At the annual meeting held in New Albany, March 3, the standard constitution and by-laws was adopted and the following officers were elected: President, Dr. Harvey S. Wolfe; vice-president, Dr. William P. Tebault; secretary and treasurer, Dr. Austin Funk; censors, Drs. Charles W. McIntire, George H. Cannon and Elihu P. Easley, and delegate to state society, Dr. Elihu P. Easley, all of New Albany.

Montana.

BEAVERHEAD COUNTY MEDICAL SOCIETY.—The physicians of the county met at Dillon, February 29, and organized a medical society, adopting the standard constitution and by-laws, and electing the following officers: Dr. Harry A. Bond, Dillon, president; Dr. Louis C. Ford, Lima, vice-president; Dr. F. M. Poindexter, Dillon, secretary; Dr. Robert H. Ryburn, Bannack, treasurer, and Dr. Maurice A. Walker, Dillon, delegate to state medical association.

Pennsylvania.

MEDICAL SOCIETY OF THE CITY OF READING AND THE COUNTY OF BERKS.—Under the foregoing title the Medical Faculty of Berks County, which was disbanded in 1870, reorganized February 23.

Tennessee.

CAMPBELL COUNTY MEDICAL SOCIETY.—Pursuant to a call by Dr. Deering J. Roberts, Nashville, secretary of the Tennessee State Medical Association, physicians of the county met in La Follette, February 6, and organized a medical society, with a membership of 16, and the following officers: President, Dr. Irwin J. Shepherd, La Follette; vice-president, Dr. Joseph L. Rose, Jellico; secretary, Dr. Joseph U. Roach, La Follette; treasurer, Dr. Frank H. McClintock, Newcomb; committee on public health and legislation, Drs. Winfield M. Caldwell, Wellspring, A. M. Riggs, La Follette, and J. L. Hefferman, Jellico, and censors, Drs. W. B. Rose, E. E. Shivers, and G. R. Wright, all of La Follette. This society has received its charter, and is receiving the hearty co-operation of the profession.

Society Proceedings.

COMING MEETINGS.

Medical Society of the Missouri Valley, Lincoln, Neb., March 24.

American Association of Pathologists and Bacteriologists, New York City, April 1-2.

Medical Association of the District of Columbia, Washington, April 5.

Tennessee State Medical Association, Chattanooga, April 12.

South Carolina Medical Association, Darlington, April 13.

CHICAGO ORTHOPEDIC SOCIETY.

Regular Meeting, held Feb. 29, 1904.

The President, Dr. A. B. Hosmer, in the Chair.

Compound Fracture of the Patella and Condyles.

DR. A. E. HALSTEAD reported a case of a man, who, while riding on the platform of a fast train, was struck by an iron girder, which produced a compound comminuted fracture of the patella. The external condyle was completely fractured, and the joint attached simply by the portion of the external lateral ligament. The patient was brought to St. Luke's Hospital, anesthetized, the parts cleansed, and the patella sutured with catgut; the joint thoroughly washed out with 1 per cent. solution of carbolic acid; a cigarette drain placed in the joint for twenty-four hours, and another one inserted at the outer aspect of the joint. The result was excellent, patient having a considerable degree of motion.

He had had other cases of compound fracture of the patella, and had always secured primary union. He had not seen infection in any of them. He attributed the good results largely to thorough antisepsis, using a 1 per cent. solution of carbolic acid freely, and *then draining the joint for twenty-four hours.*

DR. W. P. VERITY reported excision of the knee-joint three months after an injury to a boy of 14, who fell against a fly-wheel. The exact mode of injury was unknown. The result of operation was excellent.

Tuberculous Knee-Joint, with Pulmonary Complications, Excision.

DR. GAY reported this case for Dr. W. H. Allport, and showed specimens. The patient was a man, 28 years of age, who gave a history of trauma dating back two years, followed by more or less swelling of the knee, which gradually increased. About sixteen months from the time of the injury, the patient began to have a slight cough, and consulted Dr. Allport four weeks ago. Physical examination disclosed tuberculosis of the apex of the left lung, dullness, and the characteristic signs of apical tuberculosis. Practically an excision of the knee-joint was done. In the joint proper were the more pronounced tubercular lesions. Sections removed at several points and carefully examined disclosed typical tubercular formations. The bone itself was not particularly involved, except inside the capsule. Since the operation, the man had had a slight temperature, but was doing fairly well. The tubercular process involved the bursa over the great trochanter.

DISCUSSION.

DR. HOSMER said that this case raised the question of the relative frequency of the primary focus of tuberculosis, whether it occurred in the soft tissues or in bone. He asked Dr. Owens, who had seen the case, whether he thought it was capsular or osteal tuberculosis.

DR. JOHN E. OWENS replied that he was not in a position to say whether the tubercular process had involved the bone or not, but he thought it implicated other structures. He believed that the head of the tibia was involved. When the joint was first opened, a collection of material was removed which resembled in appearance a tapeworm. A certain well-known surgeon, he said, had stated that in his opinion rice bodies were tuberculous in nature. Dr. Owens had seen a few cases of rice bodies in joints that he thought were not due to tuberculosis. When a man had pulmonary tuberculosis, which was demonstrable, he usually succumbed to it sooner or later, and it was a question whether an operation should be done in such a case. He believed the consensus of opinion was against operations in such cases. At the same time, excision was performed in Dr. Allport's case, as the patient suffered excruciating pain.

DR. EDWIN W. RYERSON had seen several cases of rice bodies in the knee which were not tuberculous. He saw one knee-joint opened which contained twenty flattened bodies, which looked like pumpkin seeds. He stated that Nichols of Boston maintained that there were very few cases of primary synovial tuberculosis.

DR. A. E. HALSTEAD said that Koenig believes that fully 50 per cent. of the cases in adults are primary synovial tuberculosis. Dr. Halstead himself had seen cases in which primary synovial tuberculosis was demonstrated.

Dr. Alexander C. Wiener said that primary synovial and osteal tuberculosis were not really primary conditions; that the tubercle bacilli were carried by the blood current into the knee-joint from some other part of the body, probably the lung or the bronchial glands. The French Congress of Surgery agreed with Koenig that fully 50 per cent. of the cases of tuberculosis in adults were primarily synovial. There was no doubt but that there were cases of primary tuberculosis of the bursa above the trochanter. This might be compared with the primary seat of the disease in the synovial membrane of the joint.

Dr. Hosmer said that while he did not wish to detract from the reputation or standing of Koenig, yet as regards tuberculosis of bones, he thought one could question the correctness of Koenig's diagnoses in many cases that were not operated on. So far as he knew, the statistics of Koenig were not corroborated by skiagraphy. His own impression was that the occurrence of anything like 50 per cent. of capsular tuberculosis in children was erroneous.

Dr. Halstead said he referred to adults, not to children.

Dr. Hosmer said he had come to the conclusion that cases of tuberculosis of bones, particularly of the knee-joint, in adults, never recovered without operation. As to operating when there was already lung involvement, if the involvement was only slight, he thought it would give the patient a better chance to remove whatever focus of the disease one could. He did not think anyone, in speaking of the primary focus, referred to the atrium of invasion of the system by tuberculosis..

Dr. Hosmer also showed a case of unusually extensive resection of the knee for infection.

Dr. Norman Kerr had made observations on cases of tuberculosis of the hip joint that were operated on early by Dr. M. L. Harris, and on one or two cases by himself, in which the results were much better than by the expectant plan of treatment. He did not see why the same principle should not apply to the knee as well as to the hip.

Dr. Hosmer reported an interesting case of excision of the knee for ankylosis.

Supracondyloid Femoral Fracture, with Complications.

Dr. John E. Owen reported two cases. One was a man, aged 30, who sustained a simple supracondyloid fracture of the left femur and a compound comminuted supracondyloid fracture of the right femur. The line of fracture on the right side was just above the condyles, which were detached, the one from the other, and variously comminuted. Both legs were cold, the circulation in the right below the knee having ceased. Shock was extreme. For this he was subjected to the usual treatment, and, by the following morning, reaction having supervened, the right leg was amputated through the lower third of the thigh. The left leg was placed on a double inclined plane, abundantly padded. Dry gangrene became manifest within nine days, but it did not extend beyond the second, third, fourth and fifth toes. The leg, however, enveloped in cotton, remained warm. Eventually, moist gangrene involved a patch of skin the size of a silver dollar on the back of the foot, close to the instep. Another portion appeared on the external aspect of the leg a short distance below the knee, and still another about the middle of the leg on its external aspect. The skin, from the middle of the leg to the ankle on the external aspect, became purple, and the foot and ankle swollen. The knee was wider than normal, and the lower end of the upper portion of the femur was somewhat prominent externally.

The line of fracture was oblique and extended from above downward and outward, the upper extremity of the broken surface of the lower piece being very sharp. The popliteal artery rested immediately beneath the upper end of the lower fragment at its center, the soft tissues intervening between the vessel and the bone hardly exceeding one-eighth of an inch in the hardened specimen. A thrombus closed the artery at the point of section and extended upward doubtless to the first collateral branch. Below the line of the knee-joint a thrombus occluded the vein. The distance from a line touching the articulating surfaces of the condyles to the upper and inner extremity of the fractured surface of the lower fragment was four inches. The lower terminus of this broken surface was one inch and a quarter nearer the line just named.

This case illustrates the great danger of supracondyloid fractures of the femur. In the case of the right leg the circulation was at once arrested by the violence of the injury. In spite of the fact that the left leg was treated on a double inclined plane, the circulation became more and more enfeebled; gangrene supervened, as noted above; union at the end of twenty-five days having absolutely failed, both pulse and temperature being high, amputation of the lower third of the femur was performed Jan. 6, 1904. January 17, the progress of the case was satisfactory.

In the light of this case must the double inclined plane, on which thousands of supracondyloid fractures of the femur have been successfully treated, be discarded as the chief element in the treatment? Must the drill and the wire be employed even at the expense of opening into the knee joint in certain cases? Would section of the tendo Achilles in addition to flexion have saved this limb?

Each case presents for solution a problem essentially its own.

The second case was a man, aged 67, who was at work when an engine struck a handcar, and this in turn struck the patient, knocking him from the track. He sustained the following injuries: A linear fracture, about two inches in length, of the left frontal bone, and over this an irregular laceration of the scalp extending from the eyebrow backward four and one-half inches, the eyelids being "black and blue" and the eyeball suffused; a fracture of the left knee—a chipping off of a portion of the external tuberosity of the tibia, the fragment being freely movable and crepitus being easily elicited; a supracondyloid fracture of the right femur with marked displacement of the lower fragment forward, carrying the patella conspicuously in the same direction. The position of the lower piece, locked in this unusual position, is well illustrated in the figure. There was also a comminuted generally oblique fracture of the right tibia extending from above downward and inward, and entering the knee-joint at its upper extremity. The head of the fibula was also broken and there were two lacerated wounds, each about an inch in length, over the left patella, reaching the surface of this bone, but not entering the joint. The left leg is smaller than the right in consequence of a congenital pes planus. The anterior portion of the leg over the seat of the fractured tibia was very concave as a result of this fracture. There were no head symptoms. The left leg was encased in plaster of Paris in the extended position. The right leg, flexed to an angle of forty-five degrees, was encased in plaster of Paris from the ball of the toes to the groin, strong traction having been made by means of the hands placed behind the seat of the fracture in the tibia, during the application of the plaster and while the plaster was setting. This was done in order to relieve the deformity in the upper portion of the leg—the concavity above referred to. The leg was then suspended. All dressings were removed on the fifty-first day. The fluoroscope showed a very satisfactory apposition in the femur and tibia on the right side. The result on the left side was also satisfactory.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Regular Meeting held Feb. 29, 1904.

The President, Dr. Wendell C. Phillips, in the Chair.

The Surgery of the Common Duct of the Liver.

Dr. William J. Mayo, Rochester, Minn., said that in the majority of cases the gall bladder was infected through the bile and not by way of the common duct and duodenum, and a gall bladder once infected remained infected, needing only a disturbing element to reproduce its original intensity. In the experience of Dr. Mayo, at least 90 per cent. of all cases of common duct disease brought to operation arise from an infected gall bladder which contains stones, causing mechanical irritation, this being the most favorable condition for frequent bacterial excursions into the common duct; if this is accompanied by calculi which failed to pass the duodenal orifice then the conditions are favorable for the development of cholangitis, pancreatitis, etc. The primary importance of the gall bladder must be recognized in the etiology of these infections and operation projected at a time when the infection and stones are still in their original viscus. The cystic duct and its patency is the most important element in the problem and the question of treatment is to a large extent based on its condition. If it is closed mechanically a diseased gall bladder results, which is better out than in. The keynote to the diagnosis of this condition is that the gall bladder contains no bile. Cholecystectomy is easily performed from below upward, enabling one to carefully ligate the deep parts and to make a bloodless separation from the liver, whereas if the gall bladder be removed from above downward the same vessels will be cut over and over again, obscuring the deep field with blood. If the gall bladder contains bile, with a marked infection of the common duct, provision should be made for bile drainage to the surface, best done by a cholecystostomy and draining through natural passages. One should carefully examine the ducts for stones in all cases, even though there be no special reasons to anticipate their presence beyond the fact that the gall bladder contains stones. For all operations on the ducts Robson's method should be employed. In removing stones from the common duct the finger is the only reliable guide, if the duct is dilated from obstruction sufficiently to permit this.

Dr. Mayo stated that he and his brother had had 26 cases of chronic pancreatitis, and in most of them no stones were found, and either cholecystostomy or cholecystenterostomy was performed. All recovered. Four of these returned with a renewal of previous symptoms and, whereas no stones had been detected at the first operation, stones were found at the second operation in the ampulla in each case. He emphasized again the importance of opening the common duct and exploring with the finger in cases of chronic pancreatitis. He said that the reparative power of the common duct was not exceeded by any mucous-lined channel in the body, and he then cited three cases to illustrate this fact. He said he could not too strongly urge the complete removal of all stones at one sitting if the patient was able to bear the operation. Cholecystenterostomy is indicated by disease of the common duct and the bowel selected should be the duodenum, but in five of their cases this was impossible and the transverse colon was selected with just as satisfactory results. Appended was a table of 107 operations on the common duct, which occurred in 728 operations on the gall bladder and bile passages which had been operated on by Dr. Charles H. Mayo and himself.

DISCUSSION.

Dr. Robert F. Weir said that he was particularly glad to note that the common duct could be laid open, examined, closed, and would regain its serviceableness.

Dr. Joseph A. Blake referred to the method of reaching the common duct by liberating the duodenum for the purpose of attaching it to the cardiac end of the stomach by incising the peritoneum between the duodenum and kidney. In this way the duodenum could be readily turned to the left and the whole of the common duct inspected as well as palpated.

Dr. Willy Meyer emphasized the importance of not responding to the pleadings of patients for immediate operation, with stones in the common duct for a long time when jaundice sets in for the first time. The conditions in the common duct are more active at this time than at any other, and he advised waiting until the acute symptoms subsided before resorting to operative interference, as in cases of acute appendicitis. Stones in the gall bladder may lead to stones in the common duct and, therefore, it is important to remove the stones from the gall bladder as soon as recognized.

Dr. Samuel Lloyd emphasized the importance of preserving the gall bladder if it could be made serviceable and deprecated the advocacy by many surgeons of removal of the gall bladder in every instance of stone.

Dr. Thomas H. Manley believed that the surgery of the gall bladder had been kept back for years because of the fear entertained by many of opening the upper right quadrant of the abdomen, and to-day it was believed by many to be much safer than the surgery of the appendix.

Dr. Mayo said that in acute cases it was better to wait until the fever and initial symptoms had subsided. If the patient was without fever or chills, and was not feeling very ill, it was best to operate at once. In cases of cholangitis with very acute symptoms he said it was not a question of stones, but the infection of the ducts, and many patients died from this without being operated on. He did not believe the gall bladder should be removed unless positively indicated. The so-called ideal operation was to cut into the gall bladder, remove the stones, and sew it up. The removal of the gall bladder was determined by the amount of infection present.

Special Report of the Counsel of the Society.

Mr. Champe S. Andrews related the circumstances which led up to the arrest of Blinn and Conrad, two abortionists who have been working in this city for years. Blinn forfeited bail and fled. Conrad is now in jail, not being able to furnish $10,000 bail.

Consolidation of the Society and the Association Ratified.

Ratification of the action of the state society by each county society was announced to be requisite for the completion of the consolidation, and the action of the state society was ratified without a dissenting voice. The interest in the matter of ratification caused the hall to be packed, and there was not only perfect harmony, but enthusiasm over this further step in the peace that has now been declared after twenty-two years of discord.

LIVERPOOL BIOLOGICAL SOCIETY.

Meeting held Feb. 12, 1904.

Trypanosomes and Sleeping Sickness in Uganda.

Colonel Bruce, R.A.M.C., gave a lecture on this subject, with numerous lantern illustrations, in which, after referring to the discovery in 1888 in India of the rat trypanosome, *T. lewisi*, by Surgeon-Major Lewis, and of that surra, *T. evansi*, a little later, the lecturer proceeded to give a short history of his own discovery of the tsetse-fly parasite, *T. brucei.*

It appears that when he was stationed in Maritzburg in 1894, Governor Hutchinson asked him to go to Zululand to report on a disease among native cattle called "nagana," which threatened to ruin the natives in certain districts. When he reached Ubombo, a magistracy on the top of the Tebombo range of mountains, which here forms the eastern boundary of Swaziland, he found most of the cattle already dead, and the survivors in an emaciated condition. He set up his primitive laboratory on the veranda of a small wattle and daub hut and began the examination of the blood and organs of the animals by bacterialized and other methods. After some days a small, peculiarly shaped body began to make its presence felt on microscopic examination of stained specimens of the blood. In oxen the parasites are very scanty in the blood, so that these bodies were only seen at rare intervals. At first it was thought they were accidental, due to the stain, but after a time their parasitic nature became plain. On examining fresh preparations of blood all doubt was set at rest by the active movement shown by the bodies.

Next blood from an ox containing these active bodies was injected into a dog, and in a few days it was found that the dog's blood was swarming with the same parasites. The question was: "What are these bodies?" At first Colonel Bruce thought they might be filaria, but on turning to Cruikshank's "Bacteriology" the figure of the rat trypanosome showed him he was dealing with a parasite of the same nature. But no one knew that this disease "nagana" was the same as tsetse fly disease. A large mass of evidence on the subject had been collected by the government from magistrates, traders, sportsmen and natives, but nowhere was it stated that "nagana" and tsetse fly disease were one and the same.

In the low country near Ubombo, there was a patch of fly country and Colonel Bruce, being curious to see this interesting disease, sent healthy animals into this district to be bitten by the fly. Much to his surprise the bitten animals showed the same parasite in the blood, and so it slowly became manifest that the disease "nagana" was nothing more or less than that caused by the tsetse fly, and that the tsetse fly, instead of killing by a self-elaborated poison, really acted as a carrier of a parasite from one animal to another. Colonel Bruce remained at Ubombo for two years working at this disease, the results of which were published by the Royal Society in two papers.

When Colonel Bruce arrived in Uganda, March 16, 1903, to investigate the cause of sleeping sickness, he had no idea he would have again to do with another tsetse fly disease. Nothing could have been more fortunate for the success of the investigations. Up to that time the Portuguese commission and the first commission sent out by the Royal Society had described a streptococcus as the cause of the disease, and not the slightest whisper of a trypanosoma being the cause had been heard. One of the members of the former commission, however, in searching for the streptococcus accidentally had chanced on the trypanosoma on five occasions during his nine months' work in Uganda, and the colonial surgeon at Entebbe had also come across it on several occasions in the blood of natives attending the dispensary for slight ailments.

When Colonel Bruce heard of these observations he put all hands to the work of examining sleeping sickness cases for trypanosomes, with the result that in a few weeks he showed that all cases of sleeping sickness had trypanosomes not only in their cerebrospinal fluid, but also in their blood. He then examined the natives of the sleeping sickness area and found that some 28 per cent. of them harbored the parasite in their blood, whereas in non-sleeping sickness areas not a single native was affected.

Within a few days of reaching Entebbe, he had found that a species of tsetse fly (*Glossina palpalis*) swarmed in the vicinity of Entebbe.

By experiment he showed that this fly could convey the infection of sleeping sickness from the sick to the healthy up to 48 hours after having fed. He also showed that the flies caught in a sleeping sickness area were capable of giving the disease to healthy animals. By the aid of the chiefs he then worked out the distribution of this fly throughout the whole of Uganda and made the curious discovery that the distribution of the fly and that of sleeping sickness were identical.

Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Glandular Tuberculosis.

The following outline of treatment is recommended by *Nord. Med.* in the medicinal treatment of glandular tuberculosis:

℞.	Iodi	gr. i		06
	Ext. rhatany	gr. iv		25
	Syr. simplicis	℥iss	45	

M. Sig.: One teaspoonful morning and evening.

And the following is recommended to be placed in the bath:

℞.	Iodi	ʒiiss	10	
	Pot. iodidi	ʒv	20	
	Aquæ	℥viii	240	

M. Sig.: To be put into the bath.

Treatment of Sore Throat.

In *acute inflammations* of the throat in children, N. Filatov, in *Clin. Rev., recommends* putting the patient to bed and relieving constipation with a laxative such as castor oil or Vienna water. For gargling, a 2 per cent. solution of boric acid or sodium salicylate is of service. If diphtheria is suspected the fauces should be painted with a corrosive sublimate solution (1-1,000), or combined as follows:

℞.	Hydrarg. chlorid. corros.	gr. i		06
	Acidi tartarici	gr. viii		50
	Aq. destil.	℥iss	45	

M. Sig.: Paint the fauces twice daily.

In diphtheritic sore throat the mouth should be kept clean by rinsing or gargling or steam pulverizations. For the purpose of better diluting the mucus and saliva, alkalies are indicated:

℞.	Aq. calcis	℥i	30	
	Aq. destil.	℥ii	60	

M. Sig.: As a steam pulverization; or:

℞.	Sodii bicarb.	ʒv	20	
	Aquæ destil.	℥iii	90	

M. Sig.: To be used as a spray.

In diphtheria associated with fever, turpentine is recommended prescribed with ether to prevent vomiting and mask the taste:

℞.	Ol. terebin. gallici	℥i	30	
	Spts. etheris sulph.	gtt. xv	1	

M. Sig.: One-half a teaspoonful to a dessertspoonful twice a day. If diarrhea appears or stranguary or albuminuria the foregoing will have to be discontinued.

In the treatment of post-diphtheritic paralysis the following is indicated:

℞.	Liq. ferri sesquichlor.			
	Glycerini, āā	ʒiss	6	

M. Sig.: One to ten drops, depending on the age, three times a day after meals.

And besides employing the weak galvanic current, a subcutaneous injection of strychnia is indicated:

℞.	Strych. sulph.	gr. ss		03
	Aquæ destil,	℥i	30	

M. Sig.: Fifteen drops to be given hypodermically once daily.

In the treatment of ulcerous sore throat, accompanied by yellowish-gray exudation, the following is of service:

℞.	Potass. chloratis	ʒss	2	
	Aq. destil.	℥iii	90	
	Syr. simplicis	℥ss	15	

M. Sig.: A teaspoonful to a dessertspoonful every two hours.

Vaginitis.

The following treatment is recommended by *N. Y. and Phil. Med. Jour.* in the treatment of vaginitis:

℞.	Salol	gr. xlv-ʒii	3.-8	
	Glycerini	℥viii	240	

M. Sig.: To be applied locally on a *tampon* every second day; or:

R.	Acetanilidi	gr. xv	1	
	Acidi tannici	gr. viiss		50
	Ext. *hydrastis canad.*	gr. iv		25
	Sacch. lactis	ʒiiss	10	
	Ol. theobrom. q. s.			

M. Ft. suppos. No. i. Sig.: One to be inserted every other day.

Calomel in Tuberculosis.

Martell, in *Internat. Med. Mag.*, recommends calomel in the treatment of tuberculosis because of its elective action toward the glands and because of its action on the tissue cells and its power of combining with metabolic toxic products. Its administration is followed from day to day by a progressive increase in the secretion from the lungs and intestines. The doses in the beginning should range from grain 1/6 (.01) to grain 1/3 (.02) three times a day. If constipation is present the dose should be increased until that is relieved and then return to the original dose. The internal administration is to be accompanied by inunctions, each inunction being preceded by a washing of the skin with tincture of green soap. The mouth must be watched, and on the appearance of the least painfulness, it should be washed out with an antiseptic solution.

Within a few days, after this treatment has been started, elimination will be markedly increased from the bowels, kidneys and genitals of women. As a prophylaxis in children with a strong hereditary taint, this treatment should be employed.

The Drug Treatment of Tuberculosis.

In considering the rôle that drugs play in the treatment of tuberculosis, H. E. Stroud, in *Merck's Archives*, considers the preservation of the nutrition of the patient as of first importance. If anorexia rules the patient will die. To create an appetite he recommends the following bitter combination:

℞.	Orexin tannatis	gr. xlv	3
	Glycerini	℥i	30
	Tinct. gentianæ q. s. ad	℥ii	60

M. Sig.: One teaspoonful before each meal three times a day.

When drugs fail to create an appetite, the author resorts to the starvation method of placing the patient on a single article of food, which he particularly dislikes, for two or four days, at the end of which time he is usually hungry. To increase the nutrition cod-liver oil ranks first, which may be given with iron, arsenic and strychnia to correct the anemia if the stomach is in condition to properly absorb them. The stomach may be kept in condition by lavage, pepsin, hydrochloric acid, etc. The treatment of the cough depends on the stage of the case. In curable cases the opium preparations should be avoided if possible. In advanced cases it is the duty of the physician to relieve the cough, which is the most distressing symptom, no matter how much heroin, dionin, codein, or morphin it may require.

The fever of pure tubercular infection rarely exceeds 100.5 F., otherwise mixed infection is present. There is but one successful plan of reducing the temperature, according to the author, and that is rest in bed and the application of cold water to the hands and face, and, if necessary, the whole body, with an ice bag over the cardiac region. The most certain route to death is being up and about with a tubercular fever.

In the treatment of the fever the use of ergot is strongly condemned. A hypodermic of morphin and atropin should be given at once, and the patient put to bed and the strictest quiet enjoined. Ice may be applied to the chest, also eaten, and if the hemorrhage continues the extremities should be corded at the body just tight enough to check the return flow of venous blood. The cords may be loosened gradually and the blood allowed to flow again. This method lowers the blood pressure, and in the majority of cases checks the hemorrhage. If the hemorrhage comes from too large a vessel it must be ligated, after the plan of J. B. Murphy, of putting the lung to rest by filling the chest cavity with nitrogen gas. Another remedy which is of benefit in checking the hemorrhage is the following combination:

℞.	Calcii chloridi		
	Glycerini, āā	℥i	30
	Aquæ	Oi	500

M. Sig.: One tablespoonful three or four times a day; or:

℞.	Codeinæ	gr. ¼	015
	Pulv. adrenalis	gr. iii	20
	Calcii chloridi	gr. xv	1

M. Ft. capsula No. i. Sig.: One such capsule three or four times a day.

There is no immediate result from the calcium chlorid, but its effect is more permanent than that of any other drug.

To combat the night sweats the nutrition must be kept up and the cause of the fever removed. As a mechanical measure to be employed before resorting to drugs, three bath towels should be wrung out of cold water and applied to the back and shoulders and chest and covered by dry towels. The patient should sleep in this pack and in the morning they should be removed and the chest rubbed with alcohol. Brilliant results follow this treatment. Of drugs, sage tea, cold, at bedtime, is an old and efficient remedy in mild cases. The following combination is more preferable:

℞.	Agaricin	gr. 1/3	02
	Zinci oxidi	gr. iii	20

M. Ft. cap. No. i. Sig.: One such capsule at bedtime.

However, no remedy compares with atropin, and if it were not for the drying action of the mouth and throat no other drug would need mention. The author also states that sulphonal in 10-grain doses (.65) at bedtime tends to check the sweating, as well as to induce sleep, which makes it a very important remedy.

The intestine must be cared for and cleared out with calomel, followed by salines or castor oil. The diet should be regulated and intestinal digestion aided by the administration of pancreatin and inspissated ox gall. Fermentation should be controlled by intestinal antiseptics—the best of which is ichthoform, which also checks diarrhea.

To control the diarrhea, which is usually a late symptom, astringents are frequently required. The following combination is recommended by the author as a very efficient one in controlling the diarrhea, which is due primarily to the general toxic condition:

℞.	Bismuthi subnit.	ʒvi	24
	Ext. coto flu.	ʒi	4
	Pulv. cretæ comp.	ʒiii	12
	Tinct. opii deod.	ʒiss-ʒiii	6.-12
	Pulv. pepsini	ʒi	4
	Syr. zingiberis, q. s. ad	℥iii	90

M. Sig.: Shake and take one teaspoonful after each bowel movement.

In cases where the foregoing fails the following combination is recommended:

℞.	Cupri sulph.		
	Pulv. opii, āā	gr. i	06

M. Ft. pil. No. i. Sig.: One to three pills daily.

If constipation is present the extract of cascara sagrada combined with aloin and fel bovis is advised.

Medicolegal.

Contract by Expert for Percentage of Judgment Is Invalid.—The Appellate Term of the Supreme Court of New York holds, in the case of Laffin vs. Billington, that a contract by a physician to give expert testimony for the plaintiff in a personal-injury case and to receive as his pay a percentage of any amount realized, is invalid.

Presumption as to Continuance of Mental Unsoundness.—The Supreme Court of Indiana says, in the will case of Branstrator vs. Crow, that it is only when mental unsoundness is of a character to appear permanent, and to forbid the reasonable expectation of recovery, that a presumption of continuance will be indulged. No presumption of any kind will arise from intermittent, temporary unsoundness, such as may result from sickness, injury, intoxication or other transitory cause.

Temporary Derangement of Functions Not a "Disease."—The United States Circuit Court of Appeals, Third Circuit, holds, in Preferred Accident Insurance Co. vs. Muir, that, as used in a provision of a policy which excluded death "resulting wholly or partly, directly or indirectly, . . . from disease in any form, either as a cause or effect," the term "disease" was not intended to cover and did not apply to a temporary derangement of the functions of some organ, as, for example, of the stomach.

Exhibitions of Nervous Affections Before Juries.—The Court of Appeals of New York says that, in the personal-injury case of Clark vs. the Brooklyn Heights Railroad Co., the party suing was allowed by the court to leave the witness stand, assisted, and, at the request of his counsel, to exhibit himself to the jury in the act of writing his name and of taking a drink of water. The record represented him, through the stenographer's notes, as taking a glass of water with both hands, and as spilling the water, through the trembling of his hands, and as using his handkerchief in the same manner. The point of this exhibition was to illustrate or to emphasize his testimony that he could use his hands with difficulty, either to hold things or to drink a glass of water. The injuries received when his wagon and a street car collided consisted in the fracture of two ribs, and in various minor contusions, which did not prevent his leaving the hospital the day after.

He was a man of 57 years of age, and it was his assertion that, about two months after the accident, he was affected by a tremor, or a muscular twitching; and medical testimony was given to that effect, and of tests similar to the one described as made on the trial. He recovered a verdict of $10,000, and the appellate division affirmed the recovery, leaving the only question for the Court of Appeals that arising on the exception of the company to the party being permitted to go through his performances before the jury. It says that it thinks that the court should not have stretched its discretion to such an extent; and that, while it may not have been an abuse of judicial discretion, it was on the borderline of such an error. It is not objectionable, in these cases, that the evidence may go beyond the oral narrative, and may be addressed to the senses, provided that it be kept within reasonable limits by the exercise of a fair judicial discretion. It should be only of a nature to assist the jurors to an understanding of a situation or of an act, or to comprehend objective symptoms resulting from an injury. Examples of this class of evidence are frequent—in the exhibition of the person, and of the marks or obvious evidences of injuries sustained, etc. Personal injuries may be simulated and deception may be practiced in such exhibitions, but that can no more be prevented than can perjury in testimony. When, however, proof is attempted to be made by allowing the plaintiff to act out on a judicial stage before the jurors what he or his physicians have testified to be some nervous affection resulting from an injury, the exhibition is improper, because unfair. As something under the sole control of the witness himself, it is beyond the ordinary tests of examination. Nor does such evidence allow of any record, beyond the reporter's notes of what he saw on the trial. It is intended to prejudice the minds of the jurors, and is calculated to affect the calm judicial atmosphere of a court of justice. The plaintiff in such cases has sufficient advantages without adding to them a spectacular illustration of his symptoms. The appellate division, in its general jurisdiction to review the proceedings on trials, might well have ordered a new trial, in the interests of justice. As it is, this court is compelled to affirm the judgment, with costs, because the matter was discretionary.

Attending Physician May Answer Hypothetical Questions.—The Supreme Court of Iowa says that, when a certain physician was called as a witness in the personal-injury case of Crago vs. the City of Cedar Rapids, the parties agreed that he had been one of the attending physicians of the party suing, and no exception was taken to the exclusion of any testimony by him touching his relations to her as a physician. It was also agreed that the record should stand as if the questions propounded to the other experts had been asked him, and the objections separately interposed. The trial court then sustained the objections. Hypothetical questions, without referring to or disclosing the witness' former employment as her physician, were also held incompetent, under Section 4680 of the Iowa Code, providing that "no practicing . . . physician . . . shall be allowed in giving testimony to disclose any confidential communication properly entrusted to him in his professional capacity and necessary and proper to enable him to discharge the functions of his office according to the usual course of practice or discipline." But no communication, confidential or otherwise, was sought to be elicited, and any intention to attempt this was expressly disclaimed. The questions did not refer thereto, directly or indirectly. Manifestly, then, the Supreme Court says, the statute did not authorize the exclusion of the testimony. The record contained no suggestion of the physician's inability to disassociate the facts stated in the questions from what he had learned from his patient. Indeed, the nature of the inquiry seemed to obviate any such difficulty. If, as counsel argued, the jury might infer from the fact he had treated her; that "he knew more about the case than the experts, and would be likely to give great weight to his evidence," this would not justify the rejection of his testimony, but, rather, indicate the necessity for an instruction directing that no consideration be given to such fact. An unfavorable inference is always to be drawn from the omission of a party to call an available witness to the facts in dispute. The failure of an injured person to examine the attending physician as to the nature and extent of his injuries forms no exception to the rule. This, the Supreme Court thinks, marks the distinction between such physician and others, when testifying as experts in response to purely hypothetical questions. It is legitimate matter for the jury's consideration, and not to be obviated by any rulings of the court. The conclusion reached finds support in People vs. Schuyler, 106 N. Y., 298; Valensin vs. Valensin, 73 Cal., 106. See also Herries vs. City of Waterloo, 114 Iowa, 377. But it was insisted that the ruling was without prejudice, for that three experts were examined, and the testimony, if received, would have been cumulative in character. The Supreme Court answers that the court had not limited the number of experts which might be called on each side. Moreover, the mere fact that evidence is cumulative in character will not justify its exclusion. If evidence is cumulative to other undisputed testimony, its rejection has been held to have been without prejudice. But where there is a sharp conflict in the evidence, as there was in this case, the number or character of the witnesses often control, and the erroneous rejection of the testimony of any can not be held, as a matter of law, to have been without prejudice.

9 The Use of Obstetric Forceps. Warren R. Gilman.

1. **The Shiga Bacillus.**—Howland reports the results of autopsies in the New York Foundling Hospital, the Babies' Hospital and the Nursery and Child's Hospital. The Shiga bacillus was proved to be present in the great majority of cases by examination of the stools, but in 7 cases it was obtained postmortem by scraping the mucous membrane of the colon, and in 3 cases was obtained both antemortem and postmortem. All corresponded to the type known as the "acid," "Harris" or "Flexner-Manila" bacillus. It did not ferment glucose, saccharose or lactose, but did split mannite with acid formation. It produced an early acidity in milk with a subsequent alkalinity, and agglutinated with the "Harris" serum in high dilutions. The first 17 cases were winter cases and the last 15, summer cases. There seemed to be no difference in the histologic findings between the two. Four cases are reported in full detail and discussed. The conclusion is that the Shiga bacillus infection has a most diverse pathologic anatomy, and a large percentage of the fatal cases show no evidence of profound structural lesion. The question arises as to how much of the process is to be regarded as due to the Shiga bacillus. The evidence, the author thinks, is in favor of the belief that the primary necrotic lesion is the result of the action of the dysentery bacillus, the subsequent ulceration being brought about probably by the inter-action of various micro-organisms and the ordinary processes of demarcating inflammation. The lesions in the intestines must be considered as of two kinds: 1, Those due to the dysentery bacillus, and 2, those from toxic products of this and perhaps other organisms. He says that in summing up the evidence we shall

have to say that there are comprised under the lesions associated with the Shiga bacillus all grades and types of diarrheal disease as distinguished by clinical symptoms and pathologic findings, and that it can be affirmed that no particular type is distinguished from the others by a special etiology.

2. **Rhinoplasty.**—Beck's method is hard to explain without his diagrams. His technic consisted in cutting a triangular flap, extending from one side of the chin to the lower lip and carrying it upward to form the side of the nose. The results, while not perfect, are decidedly palliative as regards the cosmetic effect. The advantages, he thinks, are in the possibility of supplying throughout the whole area of the defect a mucous membrane which would restore normal conditions as far as possible. The broad wound-surfaces and the fact that the flap need not be larger than the defect because no shrinkage is to be expected, are other points in its favor. In the case reported, the patient had had recurrences of epithelioma. Whether the operation will influence the tendency to recurrence remains to be seen, but he thinks the prospects are more favorable than previously.

4. **Pyelo-Paranephric Cyst.**—In the case reported by Galaudet, the paranephric part of the cyst was so closely connected with the renal pelvis that there was not only a cavity in common, but also a continuous cyst wall, partly of paranephric tissue and partly of pelvic wall. This condition, he thinks, must be rare, as he does not find it much noticed in the literature. His theory of the case is that: 1. The first traumatism ruptured the pelvis of the kidney and also caused a hematoma, both within the pelvic cavity and within the paranephric tissue; 2, as time went on the blood was gradually absorbed, and the thickened capsule (extrapelvic portion) of connective tissue was formed from paranephric tissue; 3, the opening into the pelvis, however, remained, but the capsule was strong enough to hold any urine that might come through and prevent its extravasation; and 4, a second traumatism caused a fresh hematoma, partly by tearing the inner surface of the capsule and partly by causing small lacerations of the kidney.

5. **Ergot in Drug Habits.**—Livingston advocates his method of using ergot hypodermically in cases of drug habit, and remarks that the objections which have previously existed to this method have been practically remedied by the special efforts of some pharmaceutical houses, who have succeeded in producing a solution of ergot for hypodermic use which does not cause local inflammation when properly injected aseptically. The first step is the complete discontinuance of the use of the narcotic, and insuring that the patient has no access to the drug or any substitute. Within twenty-four to thirty-six hours there will begin in the extreme cases a violent reactionary stage, the basis of which is a dilated state of the blood vessels in the nerve centers, and this may be modified by the action of ergot on their muscular coat. At the same time he gives a mercurial purgative, followed in a few hours by a sufficient saline to assure prompt purgation. This avoids the irritating effect of a loaded bowel on the brain and cord, and prepares the digestive tract for service during the coming ordeal. He also discontinues the ordinary meals, gives abundant fluid and easily digested nourishment every three hours. The best he knows is a paste consisting of the ordinary fluid extract of beef, to which has been added the desiccated and pulverized fibrin. The whites of two eggs dissolved in a glass of cold water, to which a pinch of salt has been added, make another good three hours' interval meal. He also uses some of the cereal preparations. With the exception of the egg, it is better to give all these liquid foods quite warm or hot. Use no nutritive prepared with alcohol. The bowels should be kept open at least once a day, and better two or three times. He prefers the fluid extract of *Rhamnus frangula* for this purpose, in doses of one or two drams at bedtime and possibly also in the forenoon and afternoon. The frequency of the ergot dosing will depend on the degree of addiction and the general condition of the patient. The larger the daily dosage has been and the greater the nervous prostration, the greater is likely to be the reaction following the discontinuance and the greater should be the effort to counteract it. In general, the range would be from 2 to 3 doses per diem to one every two hours in extreme cases, the dose being .5 dram of his solution or of Squibb's new extract of ergot for hypodermic use—the two being practically the same. The morphin habitués are the hardest to treat. Compared with these the worst of the alcoholic cases is simplicity itself, if ergot is properly used. No matter what the degree of addiction, he would not for a moment consider the plan of "tapering off." He has never had in all his cases a request from the subject for his drug or a substitute after the first forty-eight hours. He says he has been repeatedly asked by a doctor-patient what under the sun he had been giving him, supposing that he had been using a substitute, as the patient had not had an ill feeling. It is desirable to avoid any hypnotic or narcotic drugs in the treatment, and while he is opposed to the "tapering-off" treatment, he admits that there are many excellent physicians who would not persist in the method he employs himself, and suggests a modified plan for their use; that is, to give with two of the hypodermics of ergot, each day, a fractional part of the quantity of morphin or opium that had been daily consumed; one-tenth part will be found sufficient if the ergot is given often enough, and gradually reducing it each succeeding day.

6. **Epiplopexy.**—Branham reports a case of Talma's operation which has these points of interest: 1, Vascular adhesions showing Nature's effort to form a collateral circulation; 2, subsequent pleural effusion with no ascites, indicating that good collateral circulation had been established for the portal system; 3, marked improvement in the patient's general condition, showing a better functioning of the liver and intestinal organs after the operation.

7. **Recurrent Dislocation of the Patella.**—The slipping or recurrent dislocation of the patella is seen almost entirely in girls and women. It is largely due to the fact that the line of pull of the quadriceps is not straight, this feature being increased in its effect by an unnaturally long patellar tendon, knock-knee or imperfectly developed anterior surface at the end of the femur. Goldthwait has treated 11 cases, 7 operative, with 13 operations, and gives the results of his experience here, describing the conditions anatomically and reporting cases. The operation which he performs at present consists in a longitudinal incision four or five inches long, extending from just below the tubercle of the tibia upward. Through this the patellar tendon is exposed and split in halves, anteroposteriorly, throughout its full length. The outer half is then cut from its attachment, passed under the remaining portion and attached to the periosteum, together with the expansion of the tendon of the sartorius at the inner side of the anterior surface of the tibia. If it is desirable to shorten the patellar tendon, the attachment can be made so that the patella is drawn down as much as is required, but this means more tension, and a hole should be drilled in the bone at the point of attachment through which the suture is passed which holds the tendon. The carrying of a piece of tendon under the other is important, as the patella is tilted, the outer portion being drawn downward and presses more firmly on the outer ridge of the articular surface of the femur, so that the danger of slipping is lessened. The attachment is made with strong silk, quilted through the tendon; the wound should be tightly closed and the leg fixed in a plaster-of-paris bandage from ankle to groin, the contraction of the quadriceps extensor being eliminated as much as possible by applying a tight-gauze bandage from the knee to the groin under the plaster. The fixation should be kept up for about six weeks. In this operation the direct pull is continued by a portion of the tendon left undisturbed, so that in case the transplanted portion fails to unite, function is still retained, and some improvement must result, as the simple removal of the outer half of the tendon changes to some extent the direction of the pull. He reports the results, which seem to be fairly satisfactory.

8. **Moderate Drinking.**—Benedict discusses the use of alcohol, and especially the dangers of moderate drinking. He thinks that in any case, while alcohol in small amounts may not produce a change in the tissues, it does retard the physical

and mental growth of youth. The habit-forming tendency must always be regarded.

15 *Enuresis. George E. Beilby.
16 Six Months' Work in a Dispensary for Diseases of the Lungs. Thomas H. A. Stites.

10. **Radioactivity.**—Wight's paper is largely a physical and physicochemical explanation of the radiation phenomena, with some therapeutic and medicolegal points mentioned. He has used the effect of high-frequency discharges in skin grafting, and describes the technic as follows: Render the granulating surface sterile; curette it to receive the grafts, and while it is still oozing place the grafts of any form desired in position and bathed in blood. Then apply the high-frequency discharge from a pointed electrode over the entire surface until the clotting is firm and the grafts are fixed on a dry surface. Any serum that is squeezed out in the process of clotting should be sponged off. The dressing is with 3 per cent. carbolized vaselin on plain sterile gauze, and is removed at the end of the third day. The progress of the growth is more rapid than with the ordinary method. Repair was hastened in some cases, in which the secondary Röntgen rays were used at the end of the first week. Six cases are reported. In conclusion, he remarks on the question of the danger of the *x*-ray burns, and refers to some cases. He suggests a blank form, containing all information in regard to the form of apparatus, previous exposure to radiation, distance, time, register of penetration, protection to the adjacent parts, and part exposed. He thinks such a blank filled out by the operator and signed by the patient will be a valuable record of the case and have the force of a waiver in the event of litigation.

13. **Congenital Hip Dislocation.**—Freiberg calls attention to the fact that this dislocation may produce very few symptoms in the first two years of life, but the abnormalities steadily increase during the period that it exists. Shortening to an appreciable extent appears with the development of the weight-bearing function only. When a child begins to learn to walk with limping the diagnosis is easily made. The radiograph, valuable as it is, can not be used with accuracy in determining the progress after reduction. Operation is feasible after the age of one year. The ease and stability of reduction when done early is notable. He says that having discovered that imperfect formation of the hip joint exists before the contact of femur and acetabulum has been markedly disturbed, it should be possible to prevent the further progress of luxation and secure a good joint. This would be accomplished by maintaining the limb in decided abduction, say 25 degrees, during the act of walking. The plaster spica worn for a period of six months in this position should rightly be considered the best means of attaining this end.

15. **Enuresis.**—Beilby has examined some 250 cases in the State Industrial School at Rochester; 75 had been under treatment for this symptom. Only 2 of them were imbeciles. There were in no case marked abnormalities of the urine or signs of vesical or rectal irritation, and in only a few cases was there enough phimosis to be assigned as a cause. He thinks that irritability of the spinal center should be incriminated as a cause in the majority of cases. He also gives great importance to the bad habit of masturbation, and thinks that it is the cause in at least 90 per cent. of all cases among youths and adolescents in institutions. The treatment should be by appealing to the moral sense, improving the physical condition and relieving the congestive or irritative condition of the lumbar cord.

19 *Running Ear. A. C. Bardes.
20 *Neuralgia Due to Dental Irritation. William J. Lederer.
21 *The Physiology of Hunger. Axel E. Gibson.

17. **Gunshot Wounds.**—Smith gives an interesting review or résumé of a treatise by H. St. John Neale, who was surgeon to a British regiment during the Revolutionary War. Smith points out how in his methods of treatment he was in some respects modern, and had remarkable success in the treatment of gunshot wounds.

18. See abstract in THE JOURNAL of March 5, p. 672.

19. **Running Ear.**—Bardes calls attention to the importance of chronic ear suppuration as leading to further complications.

20. **Neuralgia from Dental Irritation.**—The forms of neuralgia which may be due to dental disease are noted by Lederer, who suggests an examination by careful exploration of the teeth, gums and roots as to sensitiveness to heat and cold and the translucency of the tooth by the electric-mouth lamp, for pulp changes. Each tooth should be carefully percussed to determine the pericemental changes, and tested with an electric current as to its sensitiveness which frequently discloses pulp lesions. Another important measure is to question as to the systemic condition of the patient so as to bring out any predisposing factor. The prognosis of dental neuralgia is favorable unless it is associated with malaria and syphilis, and then it passes out of the hands of the dentist. The systemic condition of the patient should be looked after and properly treated, and the diet regulated, especially in Rigg's disease. If an infection like malaria exists, the exciting cause must, of course, be removed. Neuralgia may be due to injuries in extracting teeth, such as fracture of the alveolus, and this occasionally produces puzzling cases. Foreign bodies in the gums or alveolæ are frequently overlooked, and exostosis or hypercementosis may be the cause, as also impacted teeth. In many cases odontalgia is not a symptom of the malady, but the pain is reflected to another part, and these cases are frequently mal-diagnosed until the condition is properly recognized.

21. **Hunger.**—The principal point made by Gibson is that hunger can be modified by mental effort. If we keep the thoughts and images of food out of our mind the gastric secretion will receive no stimulation and the hunger be kept in abeyance. Keep the mind off the enticing subject and encourage no ideas of gratification.

27 Tertiary Syphilis of the Nose and Pharynx. (Continued.) W. Scott Renner.
28 The Treatment of Paraphimosis. Richard L. Sutton, Z. E. Lewis and John Gilbert.

22. **Biologic Blood Test.**—This portion of Robin's article gives the history of the test and a general review of the literature.

24. **Thrombosis of the Jugular Veins in Tuberculosis.**—The complication of thrombosis of the jugular vein in tuberculosis was noticed many years ago by Lasègue. Since then Aldrich has been able to find only 9 cases in the literature. He adds his own observation, which was that of an advanced case of chronic pulmonary tuberculosis with left internal jugular thrombosis and extension of the thrombus through the subclavian, down the axillary into the basilic veins, and subsequently a similar thrombosis of the other side following a similar course, with terminal cerebral sinus thrombosis by extension. In the epicritical remarks he discusses the bacteriology, suggesting that there may be a clumping of tubercle bacilli from the agglutinating power of tuberculous blood, favoring development of fibrin ferments, but the main cause must lie in

the vessel wall. Of course, it is possible that a general septic condition of the blood in late phthisis may produce a true fermentation thrombosis, but this does not explain the cases occurring early in the disease. Changes in the intima caused by lodgment of specific bacilli or other micro organisms is what he is inclined to recognize as the cause of the condition; the slowing of the current can have but little effect. Certain anatomic conditions may favor thrombosis and determine the location, thus the sitting posture with dependent limbs accounts for the frequent occurrence of femoral thrombosis in phthisis, and the rather common beginning of thrombosis in the lower end of the jugulars in various heart and lung troubles may be accounted for by the presence of valves in that situation, as suggested by Peter in 1873. Welch speaks of the eddying or whirling motion of the blood set up in this region as having something to do with the cause, and von Recklinghausen has brought forward strong evidence that this whirling movement is of great importance in determining the localization of thrombi. Aldrich adds that the distressing cough in the late stages of phthisis may also be a potent agent to pouch out the bulb and strain and distend its ill-nourished intima. The sudden aspiration of its contents alternating with the distension is certainly conducive to a vortical motion of the blood. In view of all these facts it is remarkable, he says, that jugular thrombosis is not more commonly associated as a complication of pulmonary phthisis.

26. **Epilepsy.**—Hopkins holds that one of his five cases has gone a sufficient length of time to justify him in considering the patient cured, namely, two years and one month. In the other cases a sufficient length of time has not yet elapsed to say whether or not they are permanently benefited.

32 A Case of Stab Wound of the Pons Varolii. Horace J. Whitacre.
33 Fracture of the Skull. Clarence H. Vaught.

31. **Sugar Tests.**—Schroeder examined critically the fermentation test by the saccharometer, and Roberts' test for specific gravity and the quantitative test by means of Fehling's solution. He concludes that the fermentation tests, with properly constructed instruments, give good results, and as they do not require previous purification of the urine, they are peculiarly adapted to the needs of the physician. The Einhorn fermentation saccharometer gives constant and satisfactory results when properly constructed, and when comparative tests are made at a temperature of from 65 to 75 F., and the sugar strength is within the limits of the instrument. To avoid loss of time from miscalculation in diluting the urine, two different dilutions should be tested at the same time, one serving as a control of the other. In view of these satisfactory reactions we need not lay too much stress on Fehling's solution.

35 *Demonstration on Cryoscopy. Henry W. Cattell.
36 *Pseudoparasitism Caused by the Common Clothes Moth. Joseph McFarland.

34. See editorial in The Journal, March 5, 1904, p. 652.

35. **Cryoscopy.**—Cryoscopy, according to Cattell, has a valuable though somewhat limited use among laboratory methods. It is easily applied and the apparatus is portable. Repeated cryoscopic examination of the urine taken in connection with that of the blood affords a valuable means of determining the renal sufficiency, but it should be supplemented in doubtful cases by electric conductibility, the phloridzin, dilution and other laboratory tests. It may be employed as a quantitative method for the determination of such abnormal constituents of the urine as sugar, and as a qualitative test for the presence of beta-oxybutyric acid in the urine, formalin in milk, etc. The relation of the specific gravity in health to cryoscopy is quite constant. In disease it varies much according to the conditions, the drugs taken, the temperature, the amount of sodium chlorid in the urine, etc. There is a personal equation in performing this test, which should always be determined by the testing of distilled water with the conditions to be used in the experiment and correcting the error, whatever it may be. The cryoscopic index of human blood is quite constant, —0.56 C., that of the fetus being slightly less, while the index of twenty-four hours' urine varies from —0.8 to —0.2 C. in health. Cryoscopic observations may be an important corroborative test in medicolegal cases, as in drowning and in differentiating the blood of different animals.

36. **Pseudoparasitism.**—McFarland reports a case where a common clothes moth, which has a naked caterpillar, led to the diagnosis of parasites in the intestine. It had dropped from the mattress, which was badly infested with these moths. While pondering on the first mistaken diagnosis, he became impressed with the possible danger from the breakfast cereals which are eaten raw should insect larvæ infest them.

42 Cholelithiasis, with a Report of Two Cases. John B. Shober.

37. **Eclampsia.**—Hirst holds to the nephritic origin of eclampsia, and does not believe in too rapid evacuation of the uterus and not at all in cesarean section. He would rather produce labor slowly than resort to a forced delivery, employing the elimination treatment by diuresis, catharsis and diaphoresis, which should be actively employed. For convulsions, we must eliminate the poison and quiet the nervous irritability. It is generally agreed that normal salt injections, sweats and purgation are the most reliable eliminants. Venesection may be classed among these, but he rarely uses it now. Of the sedatives, chloral and opium dispute the field. He thinks the latter intereferes with elimination, and a large dose may cause fatal poisoning in view of the inactivity of the kidneys. For the relief of arterial tension he would use veratrum viride. He closes by recommending hospital treatment for such cases.

38. **Fractured Patella.**—The summary of the treatment of this accident is given by Martin and Thomas as follows:

> 1. The conservative treatment of fracture of the patella is applicable to blow or tear fractures in which the separation of the fragments is not greater than one half inch when the knee is flexed to a right angle, and in which there is no great joint tension. Conservative treatment consists in fixation for ten days, the application of adhesive strips to approximate the fragments, the use of elastic bandages to prevent inflammatory exudation, and the employment of massage and passive movements. 2. All fractures of the patella, independent of the amount of fragment separation, attended by marked and immediate joint tension, should be treated by the open method. 3. All fractures of the patella in which the fragments are separated more than one-half inch when the knee is bent to a right angle should be treated by the open method; the torn tendinous expansions of the quadriceps being closed by mattress suture, and the patellar fragments being united by silver wire, the insertion of the latter being facilitated by the use of a bone drill with an eye in its boring end.

The article is illustrated by skiagrams and drawings.

39. **Dionin.**—This remedy is highly spoken of by Reber, who holds that it has properties possessed by no other drug. It is an analgesic of value, relieving the pain of iritis where atropin fails. It enhances the value of atropin, and is a powerful dilator and lymphagogue in the eye. If used to the point of distinct reaction, it promotes the absorption of exudation deposits on the anterior capsule in the pupillary space, and also helps the absorption of post-operative débris after cataract. It certainly does help to clear up corneal opacities in some cases of interstitial keratitis, but is ineffective in all other forms. Its effect on glaucoma is unsettled. He thinks it

should be widely used and the results reported, so that we may have a thoroughly correct estimate of its value.

40. **Astereognosis.**—The method of treatment for this condition as recommended by Burr is educational, based on the *idea Frenkel utilized in the treatment of ataxia.* He holds that the sensory cortical cells may be diseased so as to have lost the impression of previous sensory stimuli, *yet be normal* enough to take and preserve new impressions, and that the neighboring cells may take on the function of those destroyed. He therefore recommends the simple method of re-educating the patient by handling and feeling different objects to determine the size, weight and texture. The treatment should be persisted in for weeks and months, but if there is no improvement *after a daily quarter of an hour lesson for a month,* it is hardly worth while continuing the treatment. He thinks, however, the treatment promises well in many cases.

41. **Drug Addictions.**—Goldan believes in hyoscin hydrobromate as a true specific in drug addictions, given in small dose, as the other drug is withdrawn as rapidly as circumstances will permit, giving a larger quantity at night. It is rarely necessary to give over 1/100 of a grain, and the beginning dose should be smaller. The elimination function should also be *stimulated at the same time and gastric lavage employed.* The neurasthenia should be treated afterward. A valuable remedy is glycerophosphate, given preferably hypodermically.

47 *A Treatment of Tubercular Ulcerations of the Rectum and Peri-anal Region. D. P. Mayhew.
48 Puerperal Infection. Clarence L. Wheaton.

43. **Diphtheria Antitoxin.**—Waxham reviews the statistics of antitoxin, pointing out the benefits, but reports two cases, occurring within his knowledge, of death after the injections. *He does not attribute the deaths to the injection entirely,* but partly to nervous shock and possibly also to other medication. In one case the injection may have entered the vein and to some extent can be considered the cause of death. These instances, however, he holds do not outbalance the advantages. The life-saving power of antitoxin can hardly be overestimated.

44. **Whooping Cough.**—Melvin uses atropin to palliate the symptoms in older children and in small children and infants depends on crude carbolic acid vaporized from a heated surface. He uses *formaldehyd in the same way at night, and in the day* when practicable, with older patients. He thinks the severity of the symptoms are relieved and the attack shortened in the majority of cases without serious discomfort to the patient by these means.

45. **The X-Rays.**—The therapeutic effects of the *x*-rays are discussed by Childs in a number of diseases, and he reports his experience. He thinks *in superficial malignant growths this* treatment has the advantage of leaving the smallest scar, and is also useful *in many* local disorders, like acne, rosacea and psoriasis that are resistant to other treatment. The results in tubercular glands are also encouraging, and the large masses of glands in Hodgkin's disease appear to be susceptible to this treatment. The *x*-rays should not be used in any operable deep malignant growths, except where a surgical operation would sacrifice an extremity, or perhaps, as suggested by Pusey, with a view to limiting the operation by checking the growth if operation at once is not considered advisable. The rays are useful even in inoperable growths as a palliative, and they should be used in all cases after operation as a prophylactic against recurrence. The area of exposure should be wide and the intensity and quality of the rays should be adapted to each case.

46. **The Rectal Siphon.**—Corwin suggests the use of a tube used somewhat like the stomach tube, to be employed in siphoning out the bowels and to aid Nature where it is required. The rectal siphon overcomes the difficulty and suffering when the pelvic orgns are inflamed, and of forcing a movement of the bowels when in a horizontal position.

47. **Tubercular Ulcerations of the Rectum.**—The treatment here recommended by Mayhew is to paint the ulcer with a saturated solution of trichloracetic acid, care being taken not to allow it to spread over the healthy tissue. This is repeated *the next day, and after waiting a few minutes for the acid to* act, the pellicle of tissue which has been destroyed is removed with *a curette. No anesthesia is required.* This is repeated, if necessary, until the shining fibrous layer underlying the ulcer is reached. The overlying edges are destroyed by the acid, and at the next séance will be found to have disappeared. In this way the tissue can be removed without destroying the barrier Nature has set up. An ulcer thus cleaned is dusted with some iodin-containing powder, and, if external to the anus, is covered with a dry pad well dusted with the same powder. The patient should be seen every other day, and at the next visit it will often be seen that the floor of the ulcer is covered with healthy granulations, and the mucous membrane or the skin encroaching to cover the edges. In this case the acid need not be repeated. Simple painting with Lugol's solution and dusting with an iodin powder is all that is required. As *often,* however, as the ulcer looks unhealthy and the granulations show signs of breaking down, the acid and the curette should be employed. If the ulceration is *within the rectum* the treatment should be supplemented by treatment of the rectal mucosa, which is generally catarrhal. He uses for this the fluid extract of krameria twice daily in the proportion of 1 and 1½ ounces to the pint of hot water followed by a dram of a 5 to 10 per cent. solution of protargol, which is to be retained. *In this way the ulcer is converted into a simple ulcer and there may be some pain, but this, as a rule, is a good sign.* He reports several cases.

American Journal of Insanity, Baltimore.

January.

49 *The Anatomical Facts and Clinical Varieties of Traumatic Insanity. Adolf Meyer.
50 Apparent Recovery in a Case of Paranoia. Richard Dewey.
51 *Notes on Malignant Growths in the Insane. John R. Knapp
52 A Report of a Case of Myoclonus Epilepsy. Irwin H. Neff.
53 *The Present Status of Paranoia. William McDonald.
54 *Korsakoff's Psychosis—Report of Cases. Harry W. Miller.
55 *Paranoid Dementia.* C. W. Page.

49. **Traumatic Insanity.**—Meyer reviews the general subject of *traumatic insanity, including all the various types,* and offers the following classification:

1. The direct post-traumatic deliria with the following subdivisions: *a,* Pre-eminently febrile reactions; *b,* the delirium nervosum of Dupuytren, not differing from deliria after operations, injuries, etc.; *c,* the delirium of slow solution of coma with or without alcoholic basis; *d,* forms of protracted deliria usually with numerous fabulations, etc. (with or without alcoholic or senile basis). 2. The post-traumatic constitution: *a,* Types with mere facilitation of reaction to alcohol, grippe, etc.; *b,* types with vasomotor neurosis: *c,* types with *explosive diathesis; d, types* with hysteroid or epileptoid episodes with or without convulsions (such as most reflex-psychoses); *c,* types of p[illegible] 3. *The traumatic defect conditions: a,* P[illegible] to aphasia; *b,* secondary deterioration in [illegible] psy. *c,* terminal deterioration due to progre[illegible] the primarily injured parts, with or without arteriosclerosis. 4. Psychoses in which trauma is merely a contributory factor: *a,* General paralysis with or without traumatic stigmata; *b,* manic-depressive and other transitory psychoses, catatonic deterioration and paranoiac conditions, with or without traumatic stigmata. 5. Traumatic psychoses from injury not directly affecting the head.

The outcome has not been so unfavorable in his cases as Guder's statistics show, though the time is too short to settle the question. Aside from what is indicated symp*tomatically, the possibilities of therapeutic interference* are not very great. In any case depression of the skull should be looked for, and also clots even where no injury is noticeable. Where no indications for operation are present the avoidance of alcohol and irritating factors is of decided importance.

51. **Malignant Growths in the Insane.**—Knapp has analyzed the cases *occurring in the Manhattan State Hospital,* east, and finds that one patient out of every 626 under treatment died from malignant growth, and of every 217 deaths one death was from this cause, a much larger proportion than is shown in the general population. Short detailed descriptions are given of some of the cases. He suggests that *failing* inhibition in the insane favors the *morbid process,* and he thinks that a systematic study of malignant growths in mental dis-

orders might be a valuable help in elucidating the general question of their origin and pathology.

53. **Paranoia.**—McDonald reviews the various forms of paranoia, so-called, and concludes that a large proportion of those so classed must fall into one of the subdivisions of the type of dementia precox. In these cases there is more or less mental impairment and hallucination. The delusions are not really systematized or fixed, and the incoherence of thought is evident in the spoken or written expressions. There is a class of patients in which the paranoid delusions occur in the natural course of development and because of defective organization. These are the original paranoiacs of some authors. There is also a paranoid form of alcoholic insanity. Though paranoid symptoms occur often in senile dementia, in paresis, in manic-depressive insanity and in melancholia, the characteristic stigmata of these forms of mental disorder will aid in the diagnosis. A study of all the patients, old records and classical cases in the literature has thus far failed to present to him a case that could not be classified better in some other type than be called pure paranoia. He, therefore, apparently rejects paranoia as a distinct entity among mental disorders.

54. **Korsakoff's Psychoses.**—Miller's paper is an interesting summary of facts, and a review of the literature with a report of a number of cases of this particular form of mental disease.

63 *Modified Porro Operation. Carl Wagner.
64 Pelvic Cellulitis. R. P. McReynolds.
65 *Tuberculosis of the Female Genitalis and Peritoneum. (Concluded.) John B. Murphy.

56. **Ischuria in Retroflexion of the Gravid Uterus.**—Reed has studied this subject thoroughly, and concludes that the retention of urine in retroflexio-version is not due to direct compression of the urethra or bladder neck, mechanically closing the lumen, but must be regarded as a sort of "pressure paralysis" due to interference with the nerves supplying the bladder. Compression of the principal motor nerve is the most common cause. The part most subject to pressure is the pelvic ganglion of the uterus, though the nerve may be affected in any part of its course. Compression of the sensory nerves may rarely produce retention. Both afferent and efferent filaments may be affected simultaneously, but the order is usually consecutive. Pathologic conditions of the pelvis and abdomen irritating the sensory fibers of the bladder cause the so-called "irritable bladder." The retention of urine postpartum and after laparotomy for tumors is due to diminished intra-abdominal pressure, weakness of the abdominal muscles from over distention and the dorsal decubitus.

58. **Pseudohermaphroditism.**—Taussig concludes that we must in dubious cases do one of two things: either wait until the twenty-fifth or thirtieth year for the appearance of some sign, such as menstruation or the descent of the testicle, or perform a diagnostic laparotomy to determine the sex. After the sex has been thus determined in one or the other way then the external plastic operations that are asked for can be safely performed.

60. **Gonorrhea.**—Johnson thinks that the subject of gonorrhea is of the greatest importance, and that a very large proportion of men, even 90 per cent. according to his own observation, acquire the disease. The results in serious pelvic complications in women and the great number of abdominal sections required in their treatment, the dangers of puerperal infection and of ophthalmia neonatorum and the complications following gonorrheal infection in men are matters serious enough to call for the close attention of the physician and make him feel his responsibility in advising men who have been treated for gonorrhea as to the matter of marriage.

63. **Modified Porro Operation.**—The modified method here described by Wagner consists in grasping the cervical portion of the uterus, then inserting four forceps around the circumference so as to furnish a line for the incision and also for lifting the stump after amputation. Holding the scissors in a slanting position, he amputates the uterus with a few heavy strokes, while the moment it is opened the assistant introduces a finger to hold back the head and membranes. By holding the scissors slanting, the outer blade higher than the inner, and keeping the blade inside the uterus in contact with the mucous membrane, he avoids injury to the head and membranes, and has a conically formed stump, which allows very easy adaptation. The whole procedure in his hands only took one minute, which is a great advantage for the chance of life of the child, and was absolutely bloodless. In the case reported the patient made an uneventful recovery and left the hospital in twenty days. This modification of Porro's operation has proven in his hands safer and easier than the statistics of the ordinary Porro operation show, with a minimum consumption of time and loss of blood.

65. **Genital Tuberculosis.**—Murphy here finishes his elaborate monograph on tuberculosis of the female genitalia and peritoneum. It is too elaborate to summarize in the space we could devote to it.

Archives of Pediatrics, New York.

66 *A Study of 337 Cases of Enteric Fever in Children. Samuel S. Adams.
67 *A Study of the Condition of the Upper Air Passages Before and After Intubation of the Larynx. Also, an Inquiry Into the Method of Feeding Employed in the Cases. Louis Fischer.
68 Diastasis of the Recti Muscles in Rickets with the Report of a Marked Example in an Infant. Albert P. Francine.
69 Subphrenic Abscess in Children. John H. Jopson.

66. **Enteric Fever in Children.**—Adams analyzes and tabulates 337 cases of enteric fever in children, and notes the peculiarities. The greatest difficulty in the diagnosis was to differentiate it from estivo-autumnal malaria when the blood examination was negative. Observation and repeated blood examinations settled the question, however. The Widal test was applied in 70 cases, and gave a positive result in 86.8 per cent. The total mortality was 48, or a ratio of 14.2 per cent., but according to the periods and changes in the treatment it has been steadily decreasing so that in the last period from 1899, during which the purely hydrotherapeutic treatment has been employed, the mortality of 164 cases thus treated is only 10.97 per cent. Excluding the four cases that died of pulmonary tuberculosis during or after the fever, it would be only 8.54 per cent.

67. **Intubation.**—Fischer finds from a study of a series of children intubated in the Willard Hospital and another series taken from private practice, that intubation produces no chronic cough; that the larynx was markedly tolerant, one of his cases having worn the tube for twenty-six days, and another twenty-five; that a proper feeding tube composed of rubber leaves no evidence of chronic inflammation directly traceable to it. There was no change in the contour of the thorax from intubation, although in the majority of the children in the first series as well as in the second there was decided rachitis, and 90 per cent. of the first series suffered from some form of chronic throat disease, such as tonsillar hypertrophy, adenoids or chronic pharyngitis, or all of them together. He thinks that it is safe to assume that these conditions invite the infection. If children's throats are in a normal condition the risk of infection is reduced to a minimum.

74 *Some Observations on the Tuberculosis of Animals. D. E. Salmon.

71, 72, 73.—See abstract in The Journal of February 6, p. 391.

74. **Tuberculosis of Animals.**—This subject is taken up by Salmon, who specifies the different types of tubercle in different species of animals, and concludes that infection of the human subject from the lower animals is established by scientific facts. Almost all the cases with bacilli of the bovine type have been in children, which is noteworthy, and each of these forms a new center of infection. These bacilli may be the means of keeping up the disease in the human species. The human organism seems to have the power of attenuating tubercle bacilli and gradually making them less and less harmful, but this is counteracted by the infusion of pathogenic germs from animal sources.

104 Scarlet Fever. Emery H. Bayley.

99. **Appendicitis.**—Schmauss considers that the operation for this condition requires more than the average skill, and not every physician can handle it safely. Complicated cases require the experienced surgeon. The large mortality from appendicitis, he thinks, is due to the "wait and see" policy and incomplete operations, faulty technic or after-treatment. More lives have been sacrificed by the policy of postponing than by other causes, and the interval operation has a higher mortality than it is credited with. In mild cases we should not wait for the interval operation. He thinks Ochsner's treatment is a great advance, but does not agree with him in that circumscribed abscess is comparatively harmless or that we should let perityphlitis go to abscess formation. In the diagnosis, leucocytosis ought to help us in determining whether there is an abscess. Frequently a single symptom may require operation, such as severe pain, rigidity, etc. The teaching to operate immediately or wait until the interval are both of them misleading; the local and general conditions of every case will have to be considered. He suggests the advisability of operation in all primary cases, but does not urge it, or even recommend it, excepting in cases of considerable severity or of necessity. He believes in the timely operation in all recurring cases, and immediate operation in all severe cases. While there is some risk from moving, still it is better to transport the patient to a place where he can be properly operated on than to leave him in unfavorable surroundings. Good medical treatment under unfavorable conditions for operation is better than poor surgical treatment. There is no telling what the next attack is going to be from the character of the previous one. Schmauss favors drainage in septic cases, and believes that the removal of the appendix is advisable. In conclusion he remarks on the defectiveness of statistics, and the need of more efficient clinical, anatomic and pathologic classification.

100. **Epileptic Automatism.**—Some interesting cases of double consciousness or epileptic automatism are reported by Sweeney, who considers that unconsciousness should be the criterion of epilepsy. The consciousness is affected in various degrees and for various periods of time, from the profund absence in motor epilepsy to the momentary hiatus of petit mal. All the functions of the brain may be involved or only a single one. The faculty which is constantly absent in epilepsy is that of conscious memory, while organic memory flourishes in nearly full perfection.

1. **Specific Gravity of the Blood.**—Of the methods of determining the specific gravity of the blood, the pycnometer is the most exact. Some methods such as that with the Schmaltz capillary pycnometer are inexact or too laborious, but Hammerschlag's method, Baumann asserts, is well adapted to the clinical practice. Baumann has used this method with the chloroform-benzol mixture, and also has performed control experiments. He finds that Hammerschlag's method yields uniform excessive readings, the error amounting to .012 in excess of the normal. From the whole of his investigations he arrives at the following conclusions:

1. Provided the same hydrometer is used, Hammerschlag's method of estimating the specific gravity of the blood is clinically easily applied and yields, both in health and disease, results which are uniform and reliable. 2. An error is associated with the use of this method, which is always in the direction of an excess. The excess is, however, uniform and constant. 3. As was shown by A. G. Levy, the error may readily be obviated by the use of a specially standardized hydrometer, or by the application of the rough method of correction suggested by this observer.

2. **Temperature.**—The evolution theories imply the derivation of the warm-blooded from the cold-blooded animals and physiologic facts support this conclusion. Newly born pups, kittens and rabbits have a low temperature. The warm-blooded animals can be divided into two classes: those at birth blind, helpless, and in some cases naked and incapable of regulating their temperature, and those which are born in a condition of greater development, and can keep their body temperature at a fairly constant level. Birds are classified in the same way. What is true of some of the mammals is also true of the human species. It is only within narrow limitations that the new-born responds to changes in the temperature as does the adult. The range of temperature in healthy man and animals has not been adequately determined. The evidence shows that only the rectal temperature represents the true internal heat of the body. The temperature in the stream of urine is next in accuracy, though the method is limited in its application. The internal temperature of a healthy man shows a range from 96.8 to 100 F. These are the average for the rectum and urine, and do not include the full physiologic range. Muscular work causes a marked rise in the temperature, which may go up to 101 or 102 without causing pathologic effects. There is no evidence to show that a rise in the internal temperature is injurious, in fact the evidence seems to be increasing that it may be beneficial. Pembrey holds that heat stroke and heat exhaustion are not due to germs, but to the disturbance of the nervous control of temperature brought about in most cases by muscular exercise in unsuitable clothes and in hot surroundings laden with moisture. In the case of a

phthisical patient, the rise of temperature after exercise is not of as much diagnostic value as the reaction after exercise and the temperature during rest. It is probable that many patients with slightly elevated temperature have been enfeebled by enforced rest in bed. In the healthy man the control of temperature is the same, regardless of the external conditions, provided normal metabolism can be kept up, and it correspondingly increases in cold temperatures. The idea that we should ward off colds by guarding against low temperature is a fallacy; colds in all probability are infectious diseases. Alcohol and anesthetics both lower the temperature; the lowest temperature recorded in a man who has recovered appeared to be in a drunkard who had been exposed to the cold. Anesthesia is a decided lowerer of temperature, and it is probably often too deep and prolonged. Pain may be a natural safeguard; it brings about the proper reactions to sensation which the anesthetic suppresses. A drug that will so profoundly disturb the nervous control of combustion can not be harmless, and the author suggests that many deaths are due more to the anesthetic than to the operation. The limits of bodily temperature compatible with life, so far as have been observed in pathologic conditions, seem to range from about 75.2 to 114.8 F. Higher and lower temperatures have been observed in moribund cases, but not where recovery took place; 114.8 appears to be the highest temperature endured by any patient who recovered, and then it was continued for only a very short time.

3. **Chronic Rheumatism.**—Acute rheumatism, Stockman holds, is a microbic infection running a regular course. It never becomes chronic, properly so-called, any more than typhoid or diphtheria. The name chronic rheumatism, however, has been long applied to special joint conditions, of which we are now distinguishing a number of varieties and separate species, and it is recognized that the parts implicated in true chronic rheumatism are the fibrous ligaments of the joint, more especially the fibrous tissue of the muscles and bones. The pathologic changes are confined to the white fibrous tissue and indurations occur which can often be felt in certain exposed localities. Muscle movement by increasing tension or by exerting pressure on the swollen tissue aggravates the pain. It is common for these fibrous thickenings to occur as accompaniments and sequelæ of acute rheumatism and continuing after the symptoms of the original acute attack have gone. They may also occur after influenza and febrile diseases. Chronic rheumatism is not a diathesis, but a local affection of fibrous tissue, and results from various causes. The symptoms are well known. For treatment of the acute exacerbations, massage, baths, phenacetin, sodium salicylates, etc., may be of value, but the relief is only temporary. To obtain a permanent cure the induration must be dispersed, and the only means Stockman has found of special and definite value are massage, exercise and faradism. The injection of a solution of chromic acid is also sometimes of value. Massage is the most effective. Chromic acid injection is only possible when the nodule is sharply defined and can be penetrated by the hypodermic needle. Superficial nodules should never be treated in this way, as the solution is apt to damage the skin and cause abscess. Ten minims or less of a 1 per cent. solution in water may be given. It causes temporary pain, but great consequent relief by shrinking of the swelling. If chronic indigestion is present, and especially lumbago, a mild purgative is advisable. There are no specific remedies, and the action of palliative remedies is not curative. The water cure may be of use in some cases. In diet the main rule is to avoid gastro-intestinal ferments and the absorption of irritant products. Residence in a dry stimulating climate may bring about a permanent cure. Certain nodules after prolonged massage may remain hard and refuse to dissolve, and these may be removed surgically with complete relief. In recent cases the prognosis is good and prolonged treatment may cure the older ones. Even in incurable cases, massage and stretching manipulations may give some freedom of movement. For prophylaxis he suggests careful treatment after rheumatic fever, influenza, etc., by massage, electricity and baths.

4. **Scurvy from Sterilized Milk.**—Ashby calls attention to the possibility of scurvy from defective milk, and briefly reports a case. He thinks there is a need of careful investigation of the results of sterilized milk feeding and haphazard methods of administrating municipal milk depots are to be condemned.

5. **Beri-Beri.**—Durham finds that the metabolism in beriberi is seriously diminished, the amount of urea, phosphoric and sulphuric acids in the urine may be greatly reduced, and it is suggested that the contributing organs, for example the liver, are seriously disordered in their output, which agrees with the fact that the patients complain of illness before the onset of marked symptoms of the disease. The conjugated sulphuric acid and the neutral sulphur do not appear to be proportionately diminished in output. The purin bodies are not of such great interest in beri-beri as might be anticipated. They are abundant in critical urination of highly edematous *cases. In a number of Tamils (Southern Hindoos)* the excretion of urea and phosphoric acid was remarkably low, though the uric acid was high.

8. **Removal of the Crystalline Lens in High Myopia.**—Snell has operated on 40 patients and 59 eyes. It is sometimes well to be content with operating on one eye, and his rule has been to take the worst one. Where operation on the second eye was demanded he has been more willing to perform it on young adults than on others; 28 operations were performed on eyes, with 20 dioptics and above, and the lowest degree for which removal of the lens was performed was 10 D., and this in only one instance. If the operation is limited, as Snell believes it should be, to cases with myopia of 14 D. and upward, the number will necessarily be small. Out of 3,162 patients roughly divided into those with a myopia of 10 D. and above, and those of 10 D. and under, there were only 320 in which there was over 10 D., or a trifle over 5 per cent. Extraction was deemed unsuitable, and in every case the transparent lens has been needled, and at the end of the week, sometimes more or less, when the substance has become sufficiently broken up, an incision with a broad needle has been made a little distance inside the periphery of the cornea and the softened lens has been allowed to escape or has been coaxed out with the aid of a curette, the pupil having been previously dilated with atropin. By keeping the situation of the corneal wound inside the limit to which it dilates the danger of entanglement of the iris in the wound is materially lessened. The operation is similar to that frequently performed for zonular cataract. In all the cases a watch must be kept for increased tension, which is liable to be set up by a swelling of the lens, and in a few of his cases glaucoma has supervened, but removal of the broken-up lens immediately relieved the condition. When operating the endeavor is to remove as much of the softened lens as will escape without undue pressure on the globe. What remains will be absorbed, but further needling may be required. Needling may also be required for opaque capsule, and the treatment be somewhat prolonged. With care as to asepsis and the use of antiseptic solutions the dangers of the operation are trifling. The use of any suction apparatus is altogether unnecessary. It is desirable to keep the patient under close observation after needling in order to be prepared for pressure complications. In case they occur atropin may be discontinued and eserin substituted, but it will frequently fail to overcome the glaucomatous condition. The best plan is to tap the anterior chamber and to repeat, if necessary, the paracentesis. The danger of detachment of the retina from removal of the lens in high myopia is avoided by this method. Stockman has never extracted a lens for this condition.

16 A Case of Gangrene of the Right Foot Occurring in the Newly Born. Digby Cotes-Preedy.

9. **Muscular Structures of the Heart.**—Keith points out that the ordinary explanations of the cause of the lack of caval regurgitation from the auricles are anatomically insufficient; he explains the condition by reference to comparative anatomy. He finds that in the newborn child the condition is very similar to that of a reptile's heart. There are strong membranous valves which prevent regurgitation. In the adult the valves are reduced and muscular bundles take their place to some extent, but still leaving a chance for regurgitation with an engorged auricle. The article is illustrated by diagrams, which aid the explanation of how the auricular mechanism is constructed and how it acts. He discusses the conditions in pericarditis with adhesions, etc., as affecting the circulation and the heart's functions.

10. **Head Injuries.**—English's second lecture discusses the consequences of head injuries, aphasia, agraphia and loss of arithmetical and musical faculty, traumatic somnambulism, lesions of the cranial nerves, facial paralysis, deafness, hemiplegia, etc. The diagnosis has certain difficulties. It is not always possible to show that what is attributed to head injury is really due to it. The possibility of malingering and exaggeration must always be kept in mind. The prognosis should always be guarded. For general treatment he insists on physical and mental rest as of first importance. The patient, however, should not be isolated, as this may do more harm than good. He should be under the care of a medical man who will see that the details of treatment are properly carried out, and he should not be sent away on a long sea voyage or to travel if because of no other reason than of the inability to exercise proper supervision. With mental quiet there should be continued high feeding and general massage. For drugs he condemns the bromides. They are useful in other conditions, but not in this. He sums up the general conclusions in regard to the treatment as follows:

> 1. In rather more than half of the cases cure may be brought about by medical measures; prolonged mental rest and the proper administration of mercury are the essential points. 2. In a few of the cases the symptoms are mainly due to chronic osteosclerosis, and such cases may be almost certainly cured by trephining. 3. In the remainder of the cases the symptoms are more persistent and do not yield to general measures or to the removal of thickened bone only. I believe that in such cases these symptoms are the reflex results of lesions or irritations of the dura mater; and if the injury has involved the vault of the skull cure can be effected promptly by excision of the thickened or adherent dura mater and removal of any other source of irritation which may be present.

He insists on the free opening in surgical cases and the operation in two stages in case of extensive brain lesions, as lessening shock and mortality.

12. **Rheumatic Infection.**—The different forms of complications of rheumatisms are discussed by Dally, who suggests that in many cases the organism persists in the infected tissue after all obvious inflammatory signs and symptoms have disappeared. It exists in comparatively, but not absolutely, harmless conditions, and is capable of being called into action. His belief is based on the cardiac disease occurring at varying periods after rheumatism, the recurrence of rheumatic affections themselves, the prolonged course of the chorea and endopericarditis in childhood. He summarizes that a certain similarity of effect, whatever tissue is infected, is apparent, and the capability of such infection to inflict any degree of damage on the tissues attacked within certain limits and to persist in the infected tissues, is also supported by observation.

13. **Pleurisy.**—Dally's conclusions in regard to the radioscopic shadow in pleurisy are that the level of the fluid changes with the position of the patient unless the quality of the fluid is great or is encysted by adhesions; that a pleuritic effusion yields a shadow of greater density than a serofibrinous effusion; that the shadow is homogeneous, and in the case of serous effusion gradually increases in density from above downward; that however far the heart is displaced to the right, in most cases little alteration takes place in the position of the apex relative to the base; that, other conditions being equal, the heart is displaced more when the effusion is left-sided; and that a somewhat triangular shadow, not normally visible, above and continuous with the shadow of the heart and pericardium, is cast by the mediastinum, displaced by lateral pressure toward the left side. In the majority of cases he thinks the results of radioscopic examination correspond with those of percussion. Where they differ the explanation may be as follows: The lung is liable to become adherent by a portion of its surface to the chest wall. The level of the fluid being represented by a straight line, the lung dipping into it may be represented by a curve, with its convexity below. The thin layer of fluid and the air-containing lung, opposite to where the lung dips into the fluid, may be seen as a lighter and more transradiant area, convex below, whereas at the sides where only fluid is present and no lung the shadow will be much more dense. In all the cases he has seen the serous effusion throws a light shadow usually with a well-defined curved upper margin. A purulent effusion throws a dense or even opaque uniform shadow. In the former case the rib outlines are not obliterated; in the latter they generally are. Pleural effusion can be distinguished, unless too great in amount, from thickening of the pleura by the changes of the level of the upper margin on movement, hence the *x*-rays may frequently show whether the difficulty is present in the chest or not, and from the density of the shadow give an idea as to the exudate.

19. **X-Ray Treatment of Cancer.**—Tuffier argues that different kinds of cancers present different kinds of growth, particularly when in different parts of the body. This varying severity of the growth renders a *varying* scale of treatment necessary. What is effectual for one kind or in one location is powerless against another kind or the same kind elsewhere. He regards cancer as a disease with local manifestations, but usually under the dependence of a general condition whose nature is still unknown. A scrap of cancer grafted on a subject already invaded by cancer rapidly entails a new cancer growth, but not on a non-cancerous subject. For instance, he removed an epithelioma from the forearm of a woman, and closed the defect with a "bridge flap" of healthy skin from the abdomen. Seven weeks later she returned with an epithelioma in the abdomen at the point where the flap had been taken. Refusing an operation, she succumbed two months later to cancerous infiltration of the wall of the abdomen and thorax. In regard to serum treatment of cancer, his experience has shown that the first injections of almost any serum are followed by marked improvement, but that this soon subsides. His impression is that the serum rather accelerates the course of the affection on the whole. The serum induces a phagocytosis which temporarily arrests the tumor, but as soon as the organism has thus used up its reserves, the neoplasm continues its course unmolested. Change to another kind of serum and to a third and fourth produces the same kind of a transient improvement, shorter in each case, but the organism is only rendered less resistant by these demands on it. As soon as their effect subsides, the malignant disease

phthisical patient, the rise of temperature after exercise is not of as much diagnostic value as the reaction after exercise and the temperature during rest. It is probable that many patients with slightly elevated temperature have been enfeebled by enforced rest in bed. In the healthy man the control of temperature is the same, regardless of the external conditions, provided normal metabolism can be kept up, and it correspondingly increases in cold temperatures. The idea that we should ward off colds by guarding against low temperature is a fallacy; colds in all probability are infectious diseases. Alcohol and anesthetics both lower the temperature; the lowest temperature recorded in a man who has recovered appeared to be in a drunkard who had been exposed to the cold. Anesthesia is a decided lowerer of temperature, and it is probably often too deep and prolonged. Pain may be a natural safeguard; it brings about the proper reactions to sensation which the anesthetic suppresses. A drug that will so profoundly disturb the nervous control of combustion can not be harmless, and the author suggests that many deaths are due more to the anesthetic than to the operation. The limits of bodily temperature compatible with life, so far as have been observed in pathologic conditions, seem to range from about 75.2 to 114.8 F. Higher and lower temperatures have been observed in moribund cases, but not where recovery took place; 114.8 appears to be the highest temperature endured by any patient who recovered, and then it was continued for only a very short time.

3. **Chronic Rheumatism.**—Acute rheumatism, Stockman holds, is a microbic infection running a regular course. It never becomes chronic, properly so-called, any more than typhoid or diphtheria. The name chronic rheumatism, however, has been long applied to special joint conditions, of which we are now distinguishing a number of varieties and separate species, and it is recognized that the parts implicated in true chronic rheumatism are the fibrous ligaments of the joint, more especially the fibrous tissue of the muscles and bones. The pathologic changes are confined to the white fibrous tissue and indurations occur which can often be felt in certain exposed localities. Muscle movement by increasing tension or by exerting pressure on the swollen tissue aggravates the pain. It is common for these fibrous thickenings to occur as accompaniments and sequelæ of acute rheumatism and continuing after the symptoms of the original acute attack have gone. They may also occur after influenza and febrile diseases. Chronic rheumatism is not a diathesis, but a local affection of fibrous tissue, and results from various causes. The symptoms are well known. For treatment of the acute exacerbations, massage, baths, phenacetin, sodium salicylates, etc., may be of value, but the relief is only temporary. To obtain a permanent cure the induration must be dispersed, and the only means Stockman has found of special and definite value are massage, exercise and faradism. The injection of a solution of chromic acid is also sometimes of value. Massage is the most effective. Chromic acid injection is only possible when the nodule is sharply defined and can be penetrated by the hypodermic needle. Superficial nodules should never be treated in this way, as the solution is apt to damage the skin and cause abscess. Ten minims or less of a 1 per cent. solution in water may be given. It causes temporary pain, but great consequent relief by shrinking of the swelling. If chronic indigestion is present, and especially lumbago, a mild purgative is advisable. There are no specific remedies, and the action of palliative remedies is not curative. The water cure may be of use in some cases. In diet the main rule is to avoid gastro-intestinal ferments and the absorption of irritant products. Residence in a dry stimulating climate may bring about a permanent cure. Certain nodules after prolonged massage may remain hard and refuse to dissolve, and these may be removed surgically with complete relief. In recent cases the prognosis is good and prolonged treatment may cure the older ones. Even in incurable cases, massage and stretching manipulations may give some freedom of movement. For prophylaxis he suggests careful treatment after rheumatic fever, influenza, etc., by massage, electricity and baths.

4. **Scurvy from Sterilized Milk.**—Ashby calls attention to the possibility of scurvy from defective milk, and briefly reports a case. He thinks there is a need of careful investigation of the results of sterilized milk feeding and haphazard methods of administrating municipal milk depots are to be condemned.

5. **Beri-Beri.**—Durham finds that the metabolism in beriberi is seriously diminished, the amount of urea, phosphoric and sulphuric acids in the urine may be greatly reduced, and it is suggested that the contributing organs, for example the liver, are seriously disordered in their output, which agrees with the fact that the patients complain of illness before the onset of marked symptoms of the disease. The conjugated sulphuric acid and the neutral sulphur do not appear to be proportionately diminished in output. The purin bodies are not of such great interest in beri-beri as might be anticipated. They are abundant in critical urination of highly edematous cases. In a number of Tamils (Southern Hindoos) the excretion of urea and phosphoric acid was remarkably low, though the uric acid was high.

8. **Removal of the Crystalline Lens in High Myopia.**—Snell has operated on 40 patients and 59 eyes. It is sometimes well to be content with operating on one eye, and his rule has been to take the worst one. Where operation on the second eye was demanded he has been more willing to perform it on young adults than on others; 28 operations were performed on eyes, with 20 dioptics and above, and the lowest degree for which removal of the lens was performed was 10 D., and this in only one instance. If the operation is limited, as Snell believes it should be, to cases with myopia of 14 D. and upward, the number will necessarily be small. Out of 3,162 patients roughly divided into those with a myopia of 10 D. and above, and those of 10 D. and under, there were only 320 in which there was over 10 D., or a trifle over 5 per cent. Extraction was deemed unsuitable, and in every case the transparent lens has been needled, and at the end of the week, sometimes more or less, when the substance has become sufficiently broken up, an incision with a broad needle has been made a little distance inside the periphery of the cornea and the softened lens has been allowed to escape or has been coaxed out with the aid of a curette, the pupil having been previously dilated with atropin. By keeping the situation of the corneal wound inside the limit to which it dilates the danger of entanglement of the iris in the wound is materially lessened. The operation is similar to that frequently performed for zonular cataract. In all the cases a watch must be kept for increased tension, which is liable to be set up by a swelling of the lens, and in a few of his cases glaucoma has supervened, but removal of the broken-up lens immediately relieved the condition. When operating the endeavor is to remove as much of the softened lens as will escape without undue pressure on the globe. What remains will be absorbed, but further needling may be required. Needling may also be required for opaque capsule, and the treatment be somewhat prolonged. With care as to asepsis and the use of antiseptic solutions the dangers of the operation are trifling. The use of any suction apparatus is altogether unnecessary. It is desirable to keep the patient under close observation after needling in order to be prepared for pressure complications. In case they occur atropin may be discontinued and eserin substituted, but it will frequently fail to overcome the glaucomatous condition. The best plan is to tap the anterior chamber and to repeat, if necessary, the paracentesis. The danger of detachment of the retina from removal of the lens in high myopia is avoided by this method. Stockman has never extracted a lens for this condition.

13 *Radioscopic and Radiographic Appearances in Pleurisy, with Especial Reference to the Upper Limit of Pleural Effusion. J. F. Halls Dally.

The fluorescing screen is a sheet of very thin celluloid, coated with calcium or zinc sulphid in the center, the round patch about 1 cm. in diameter, the sulphid spread so thin that print can be read through it. The screen is "excited" by being held near a source of ultraviolet rays, and the fluorescent light is then allowed to die away until it has reached the steady stage. If a contracting muscle be then placed under the screen, its light will be seen to become perceptibly brighter. One of the most convincing tests is to place a feebly fluorescing screen on the floor by the bare foot in a dark room. It is almost impossible to make out the screen under these circumstances, but if it is placed on the toes, and they are worked, the screen glows so that it can be readily seen by the standing subject. After simply placing a speck of recently excited calcium sulphid on a thick book a distinct increase in the glow is obvious when the muscles of the hand or arm are contracted underneath. We notice in this connection that Mendeleef, the great Russian chemist, the discoverer of the "periodic law" of chemical elements, has recently published his belief that the ether is a highly penetrative, elastic gas, a real chemical entity, and that it is responsible for the phenomena of radio-activity.—Ed.]

37. **Nerve Stretching in Raynaud's Disease.**—De Bovis gives the particulars of 2 cases of symmetrical gangrene of the hands, which were practically cured by stretching the cubital and median nerves at the wrist. He advises careful hygiene of the parts and general tonic treatment, and adds that the stretching of the nerves does not radically cure the affection, but improved it to such an extent in his cases that the measure should certainly be given a trial in every case. It has a favorable influence on the dystrophy, but should be supplemented by frictions and local baths, etc., to promote the circulation in the parts, with removal of the gangrenous patches. The latter is the only measure that will certainly relieve the pains in all cases. The disease is more than a mere disturbance in the trophic innervation, and, in his cases, the cure of the trophic lesions was accompanied by no more than mere improvement in the vasomotor disturbances. The hands are still somewhat cold and subcyanotic.

38. **Mortality in European Armies.**—Dolmatoff states that the mortality from typhoid fever in the Russian army during the years 1889-1900 ranged from 1.02 to 1.91 per 1,000 (French army, .96 to 1.88 per 1,000). The pneumonia mortality was below that of the French army, but a trifle above that of the German, being .49 to .99 per 1,000. The dysentery mortality, .12 to .2 per 1,000; the French, .1 to .33, and German, .01 and .02 per 1,000. The total mortality among the privates was 6.4 per 1,000, while in the French army it was 5.9 and in the German, 2.7 per 1,000. The German army leads in the number of suicides, ranging from .33 to .64, followed by the French army, with .19 and .31, and the Russian with only .11 and .17 per 1,000.

39. **Role of Animals in Propagation of Disease.**—Bard thinks that this factor in the transmission of microbian disease is being rather overestimated at present.

40. **Phlegmonous Forms of Cancer.**—Lejars dwells on the "hints" which may serve for the differentiation of the abscesses which are the initial stage of malignant disease and not the mere phlegmons which they appear to be. These suppurating cancers, the phlegmonous varieties, generally display peculiar malignancy, with rapid diffusion, offering little prospects for effectual surgical intervention. Differentiation in the earliest stages, although difficult, is not impossible in most cases. Careful examination will reveal some suggestive features, the "exceptional" hardness of the surrounding tissues, the large base of the lesion, deep and adherent, the absence of decided limits, and the special, purplish color of the skin, while the general health also is more affected than is usual with an ordinary suppurative process. The blood findings are not characteristic.

45. **Value of Diaphoretic Treatment in Kidney Affections.**—Bendix epitomizes the results of considerable experimental research under Ebstein's direction in the statement that he found it impossible to influence the normal freezing-point of the blood by even the most energetic sweating procedures. He was unable to induce a thickening of the blood by withdrawal of water, nor, by the elimination through the sweat of substances dissolved in it, to reduce the molecular concentration of the blood. This applies to both the normal animals and those with kidney affections. In the clinic he conducted similar research on patients who had to be treated by diaphoresis and venesection at the same time—mostly cases of kidney disease. The sweating was induced with the Quincke-Dubois hot-air apparatus, and the weight of the subjects diminished by 500 to 1,500 gm. under it. The sweat was accumulated on a rubber sheet. The results harmonized with those obtained with the animals. When the freezing-point was normal—.56 C.—the most energetic sweating procedures had no influence on it. On the other hand, when the freezing-point of the blood was pathologically low, as in chronic nephritis, the sweats raised the freezing-point almost to the normal standard. This result is the more remarkable, as the sweat is usually hypotonic in regard to the blood, and the result naturally to be expected would be a thickening instead of a dilution. The findings suggest the probability that the body must always have abundant reserve supplies of water on hand somewhere, which serve at need to wash out the solid substances. He found that more solid substances were eliminated in the sweat under these circumstances than when the freezing-point remained at a constant level. This was particularly noticeable in a case of acute uremia. He does not attribute much importance to the variations in the freezing-point of the sweat, but these experiences emphasize the value of energetic sweating procedures in case of insufficiency of the kidneys—manifested in a pathologically lower freezing-point of the blood—as a means of restoring the freezing-point of the blood approximately to normal. The character of the kidney trouble does not seem to affect this result. He has also derived the impression from these researches—although unable to scientifically prove it—that ingested iodin is also eliminated in the sweat, subject to individual variations, both in normal and nephritic subjects.

48. **Intoxication from Mustard.**—Kolbe reports a case of intoxication from the use of mustard seeds taken in self-treatment for a stomach trouble. The symptoms were those of serious narcotic poisoning, contrary to what has been previously recorded from this cause. Treatment should consist in artificial respiration, then lavage of the stomach, stimulants and eventually a milk diet. Strychnin has experimentally proved an antidote for mustard poisoning, but whether to prefer it to atropin—the symptomatic remedy for the spasm of the diaphragm—is still an open question. The diagnosis in dubious cases is aided by the odor of the expired air and of the urine, distillation of the urine and stomach content with

water to obtain the ethereal oil of mustard, and mustard seeds in the stools. The patient recovered after a few days of serious illness, but died a year or so later after an operation for stricture of the ascending colon, which was found gangrenous. Otherwise the organs were normal. The case suggests the danger of mustard for internal application. It is used currently in the household as a harmless remedy and emetic, but Posner, as long ago as 1864, warned that even a tablespoonful in a glass of water is liable to set up a fatal gastritis on account of the content in ethereal oil of mustard. Kolbe thinks that the effect on the medulla oblongata is even more to be feared than its local action in the stomach.

49. **To Keep Catheters Aseptic.**—Goldberg uses a glass ring with a hooked handle to suspend the catheter in a glass test tube, plugged with cotton. Another way is to use a test tube that has a constriction at the base of the neck. This constriction holds the flaring end of the catheter or a glass ring slipped over the catheter. By the use of these tubes, with a constriction at the base of the neck, several bougies or catheters can be kept in a single bottle, all held by the flaring upper end. He sterilizes the whole with steam, and then puts the catheters in the tube, which he fills with a 1 to 3 per cent. solution of boric acid to 1 or 2 cm. above the catheters. He then pours on the top of the fluid a layer about 1 cm. thick of sterile olive oil. Patients should be instructed to have a separate tube for each catheter, but physicians can keep several in one tube. The catheter is taken out by inverting the tube.

51. **Alcohol Compresses.**—Wohl confirms the prompt benefit derived in suppurative processes from the application of compresses soaked in 95 per cent. alcohol. It causes the rapid retrogression of an incipient process and checks the progress of advanced ones without extensive breaking down. It relieves the pain also better than any other moist compress. He describes 3 illustrative cases out of an extensive experience. One patient was a young woman nursing her first infant. Both breasts were very painful, red and hard, temperature 41 C., and pulse 140-150. The day after the alcohol was applied the temperature was normal, pulse 80, and in three days the child was nursing normally.

54. **Modern Methods of Disinfecting a Plague Ship.**—Nocht of Hamburg gives the details of the disinfection of the steamer *Cordova*, which arrived from Brazil Dec. 25, 1903. Every ship arriving at Hamburg is searched for dead rats by the sanitary authorities. During the last year they were found in 36 ships and plague bacilli were found twice. When the *Cordova* began to unload, the inspectors found at noon seven dead rats. By 3 o'clock the ship was notified that the findings were suspicious, and it was ordered to leave the quay and anchor in the open water. The Nocht-Giemsa disinfecting apparatus was installed the same day, and the hold and living rooms were filled with the gas generated. The next morning fresh air was pumped into the hold by the same apparatus, and the unloading of the ship on lighters allowed to proceed. The cargo consisted of sacks of coffee and bran, and as each sack was brought up it was inspected by the sanitary officer. All on which there were signs of rat manure or gnawing were loaded into a separate lighter, which was isolated for a period of two weeks, with no possibility of contamination from other rats, after which the unloading was allowed to proceed without further restrictions. None of the rest of the cargo was interfered with, and it was unloaded and stored in the warehouses as usual. No plague rats were found anywhere in the ship except in the compartment where the first had been discovered, and all in this compartment had died before the gas disinfection. The gas killed 139 rats in all, including a number of nests of young rats in inaccessible crevices. The crew and others working on the ship were required to wear an outer suit while at work, with gloves, etc., and on leaving work to clean their hands and shoes with kresol soap. They were examined by a physician once a day, and for five days after the unloading of the ship was completed. Otherwise they were not interfered with. After the ship had been unloaded it was disinfected anew with lime in the hold and the living rooms with formaldehyd. All the sweepings of the ship were burned, as is compulsory for all ships in Hamburg harbor. In five days from the finding of the dead rats, the sanitary officers withdrew and the ship sailed in two days with a new cargo. A few sacks had been carried into the warehouse before the first rats were found, and they were isolated by covering them with tarpaulins and building a high board partition around them, shutting up in it a couple of trained rat dogs. After the two weeks' period was past the partition was removed and the sacks not further interfered with. The purpose of these measures was to keep the rats in the warehouse from access to the sacks during the period of isolation. No case of sickness developed among the crew or those having anything to do with the ship.

55. **Dreyer's Sensibilizing Modification of Light Treatment.**—Dreyer's important contribution to phototherapy was described in The Journal recently, page 469. Neisser and Halberstaedter have been testing it at the Breslau dermatologic clinic, and their experience entirely corroborates the great value of this method of preparing the tissues for the action of the therapeutic light rays. Attempts to explain by fluorescence and absorption the mechanism of this sensibilizing action all fail, but with it the reaction in human skin is many times deeper with a very much shorter exposure. The Finsen light treatment never reaches the depths now possible with this modification. A further advantage is that the sensibilizing fluid can be injected directly at the deep point where the therapeutic action is desired, thus sparing the superficial tissues from any intensification of the light action where it is not needed. Several stains were tried—eosin, cyanin, etc.—but erythrosin surpasses them all in its effects and also in its harmlessness. Applied in the clinic in 25 cases of lupus, spina ventosa, scrofuloderma, tuberculous lymph glands and cutaneous cancer, the strength of the reaction and its course show that the light treatment thus modified is much more energetic and effectual than ordinary Finsen light treatment. A 1 per cent. or per 1,000 solution of erythrosin in .85 per cent. salt solution was injected according to the Schleich infiltration technic as deep as the effect was desired. Two to five hours later the Finsen light was applied for fifteen to twenty minutes, or longer in case of carcinoma.

56. **Flugge's Reply to Behring.**—Flügge does not regard any of Behring's recent statements in regard to the origin and prophylaxis of tuberculosis as important except those bearing on the immunization of cattle. Even this Flügge considers a subordinate factor for the prevention of tuberculosis in man. Sufficient time has not yet elapsed to determine whether the cattle immunized by this method retain their immunity permanently.

57. **The Tuberculin Test.**—Schlüter tabulates the details of 30 cases in which the tuberculin test was applied with positive results out of a total 100. They prove that a reaction to a small dose occurs almost exclusively in subjects with an active tuberculous process, while those with a latent, inactive process and those entirely exempt do not react except in very exceptional cases. He starts with 2 mg. of Koch's old tuberculin and never surpasses 5 mg. These small doses can never do harm, he thinks.

58. **Thiosinamin in Stenosis of Pylorus.**—An intelligent man of 56 had suffered for thirteen years from gastric disturbances, due to stenosis of the pylorus. After failure of all other means of relief an operation was contemplated, but owing to the unwillingness of the family it was postponed from time to time. Attention had just then been called to thiosinamin, and it was tried as the last medical resource. One-half a Pravaz syringeful of a 15 per cent. alcoholic solution was injected into the back, and the patient's condition began rapidly to improve. In two months he was freed from the most distressing symptoms, and in another month—after the thirteenth injection—he was eating ordinary food at the family table. At date of writing he has received twenty-three injections during the five months, and considers himself cured. All the details of the case are recorded; they show that the reaction to the drug is not severe; headache and depression

were noticed only once or twice, and only after the first injections. The stools became regular soon after they were commenced, and the patient increased in weight.

59. **Representation of "Expression-Movements."**—Sommer gives illustrations of an instrument which he has devised for tests in experimental psychology. The hand placed on a floating tablet transmits its threetold movements by wires to three electric lights of different colors, the variations in the shade or intensity of the light corresponding to the movements of the hand. He has thus been able to study the movements in various nervous affections, and proposes to describe his experiences in detail at the approaching congress of experimental psychology at Giessen.

64. **Relations Between Hysteria and Female Genital Organs.**—Voss does not believe that hysteria develops any more frequently on a basis of affections of the genital than of other organs. Most of the neuroses observed in gynecology are not typical hysteria, but belong rather to the group of degenerative hysteriform tendencies. Inherited predisposition and psychic contagion are important evidence in favor of a nervous origin. Further study is needed to determine which affections in the genital sphere do not usually entail sequelæ for the nervous system. He warns that technically simple gynecologic operations, even the narcosis alone, may be of great importance in this respect and prove disastrous for the nervous system. Diversion of the attention is better for nervous disturbances. Local interventions have a tendency to aggravate the subjective symptoms on a nervous basis, or recurrences are liable after a brief period of improvement.

65. **Hyperemesis Gravidarum.**—Jung recommends strict bed rest and nothing but iced milk per os. If the vomiting continues, rectal feeding only, returning tentatively after a few days to mouth feeding. The failures of this mode of treatment are usually due to the patient's surreptitiously obtaining food. The pregnancy should not be interrupted until all other measures have been tried, including the removal of the patient to a hospital.

67. **Direct Illumination of Abdominal Cavity.**—Ott's retractors supplied with electric lights have already been described in these columns (see also page 680). He gives illustrations of them here and his method of using them, the patient in an exaggerated Trendelenburg position to cause the intestines to slide down away from the viscera being examined. He is particularly pleased with his forehead lamp and reflector which focuses a flood of light on the parts he is inspecting, especially valuable during a laparotomy, supplemented by as many small lamps introduced inside the abdomen as may be needed. The findings are shown in a number of illustrations.

68. **Lymphatics and Uterine Cancer.**—Kroemer's study of cadavers of young and old subjects has demonstrated that the number of communications between the lymphatics in the uterine region is larger than hitherto taught. Consequently he thinks abdominal ablation with removal of all suspicious glands is indicated for early cases of sarcoma or endothelioma in the uterus, and also for similar carcinomata in young or pregnant women. Also for rapidly disintegrating cases of cancer of the cervix developing by infiltration. It is also indicated in advanced cases of cancer of the portio or corpus uteri. Vaginal total extirpation will answer for incipient pure portio and corpus cancer without complications, proceeding by a liberal vaginoperineal incision and resection of parametrium. Advanced cases of the soft cancers in the first group are no longer operable. Even the most exhaustive search for infected glands will be futile. He urges an exploratory excision and microscopic examination as an indispensable preliminary to operating. In statistics those cases in which the glands were examined should be classed apart from others. He further urges that gynecologists should pay more attention to the postmortem findings. In 80 cases examined he found the parametrium infected in 44, and in half of these the glands were cancerous; in the others they were apparently free from cancerous infection. Certain kinds of cancers displayed a greater tendency than others to glandular involvement. The most malignant in this respect were always the polymorphous-celled tumors of the cervix, both the sarcoma and endothelioma class and the adenocarcinomata—all presenting in common a marked tendency to a soft, infiltrating growth.

79. **Dysmenorrhea.**—Schultz remarks that there can be no doubt that the dysmenorrhea in certain cases in girls and young nulliparæ is due to defective structural development of the infantile connective tissue in the outer layers of the wall of the uterus. After failure of all other measures it may be advisable to slit this outer capsule, from outside inward, as a last resort in certain individual cases. In palliative treatment vasoconstricting measures will be found useful, expelling the blood from the congested vessels of the parts.

81. **Improved Apparatus for Inducing Hyperemia.**—Bier's illustrations give a clear idea of the various apparatus he describes. He has been much pleased with the success of one style with which he is able to produce a vacuum around a stiff joint and thus induce a curative hyperemia. The arm or leg is placed in a wide, stout glass cylinder, a connecting rubber cuff fitting airtight around the limb above and below the glass cylinder. A contrivance like a bicycle pump aspirates the air from the interior and the part reddens, sweats and feels warm in the rarefied air. The apparatus is arranged so that the stiff joint can be subjected within it to passive and active movements, and it has proved very effectual. Its principal field is in the cure of traumatic ankylosis of the joints. His hot-air apparatus has been modified, as shown in an illustration, for use in trigeminal neuralgia. The tip of the tube has a wooden cover to prevent burning the hand, and the other end of the tube is finished with a ball and socket joint which allows the tube to be moved sufficiently to direct the stream on any part of the face. Gas or an alcohol lamp supplies the heat. The mistake is frequently made in applying superheated air that the box for the air is too small, and the heat is applied at one point instead of being diffused through the space containing the limb. He has frequently found superheated air effectual in improving cases of chronic articular rheumatism after the entire failure of electric light baths. Passive hyperemia is also liable to prove very effective in these cases. The finest results he has yet attained were with passive hyperemia in the cases of three children with very severe chronic rheumatism. He applies the constricting bandage for this purpose for twelve to twenty-two hours a day, massaging away, once or twice during the day, the edema which accumulates and is beneficial in this affection, but not in all others. The passive hyperemia is peculiarly useful for the chronic cases with a tendency to ankylosis or acute exacerbations. In the more chronic cases, passive hyperemia is less effectual than the active, as a rule, but much can be accomplished with it, although the results have not realized all his anticipations in this respect.

82. **Esophagoscopy.**—Starck states that he has used the esophagoscope one or more times on 46 patients presenting some lesion in the esophagus. Among other facts thus learned by this direct inspection is that the so-called neuroses are not so frequent as hitherto assumed. Some lesion is always found to explain them. The aspect of a diverticulum can never be mistaken or forgotten.

83. **Retention Stomach Tube for Stricture of Esophagus.**—Schiele has restored a patient to comparative health by rendering the esophagus permeable when it had been almost entirely obstructed by a carcinomatous stricture. He accomplished this by introducing into the lower esophagus a drainage tube, about 30 cm. long, with a dozen large openings. It was inserted with a guide tied to the tube with catgut at the lower end. The catgut soon dissolved in the stomach, allowing the guide to be withdrawn. A string passes through one of the holes in the upper end of the tube, and is tied around one of the teeth. With this string the tube is drawn out and a fresh one introduced every fifth day or thereabouts. The patient is a man who had been reduced to a skeleton before this intervention, the esophagus not allowing the passage of more than a glass of fluid during the entire twenty-four hours. He is now able to eat any quantity of soft eggs, thick soups, etc., and experiences no discomfort from his tube. If by any mischance it should escape and slip down into the stomach, Schiele does not think that this would be much of a calamity under the circumstances.

86. **Lung Affections in Glassblowers.**—Prettin found that the muscles seem to adapt themselves to their task so that glassblowers are not apparently more liable than others to have pulmonary emphysema. But, on the other hand, he found an unusually large proportion of tuberculous lesions among them. Fully 20 per cent. of the workmen presented evidences of a tuberculous lung affection, while emphysema was observed in only 5 out of the 230 glassblowers examined. It was very slight in the 2 subjects between 40 and 50 years old, and the 3 others were 52 to 58 years old, and had been glassblowers for thirty-four to forty-three years. He cites Fischer to the effect that not a single instance of emphysema was found in 500 members of military bands, as he published in 1902.

90. **Suprarenin to Artificially Induce Anemia in Operations.**—Müller relates experiments with suprarenin as a means of preventing bleeding during operations. He waxes enthusiastic over its virtues in this line, especially for operating on the liver. It is also extremely valuable for expelling the blood to allow better oversight of the conditions anywhere. In extirpating the thyroid or a salivary gland a 1/10,000 solution effectually expels the blood from all the finer and medium-sized vessels. The walls even of the arteries contract so that fewer ligatures are required, the field is cleared and the nerves can be more readily traced. His experiments were conducted on dogs, and he found that all kinds of minor operations on the neck could be done without the flowing of a drop of blood. He gives a table of 70 major operations performed on dogs, laparotomies, cystectomies, resection of liver, nephrectomies, etc., after preliminary injection of the suprarenin. There was only slight bleeding in 22, and none at all in the 52 others. The 1 per 1,000 and 2,000 solutions induce anemia immediately in all kinds of tissue, and may be used in this strength in operating on the kidney and liver, but a 1 per 5,000 or 1 per 10,000 is sufficient for the purpose in skin, fat and muscle tissue. The anemia is complete, either immediately or not later than two minutes. He announces that as much as 10 c.c. of the 1 per 1,000 strength may be safely injected into an adult without fear of indications of intoxication. In these strengths the suprarenin has no injurious influence on the living cells. He also proclaims that a 1 per 10,000 and 20,000 solution has a stimulating action on the heart muscle when injected directly into it, and 1 c.c. of this strength may be injected into the myocardium without harm. For inducing anemia the suprarenin must be injected directly into the tissues, as applied externally its action is not so apparent. It is destined to prove a great help in operating on debilitated and other subjects who have no blood to waste. Its action is apparent by the yellowish tint assumed by the tissues, and its influence lasts for a long time, sometimes for several hours. No after-hemorrhage has ever been observed in any instance, and need not be feared. Suprarenin is readily soluble in water, can be sterilized by boiling, and the solutions should be made with physiologic salt solution. The injections are not painful, but if desired they may be preceded or accompanied by local anesthesia. He found for general use that the best syringe was one with a capacity of 5 c.c. and a very long, thin needle. For the liver he prefers a blunt needle with an opening in the side. In his clinical experience with the suprarenin he found that the anemia was not so rapidly induced in inflamed as in sound tissues, but the extreme limits are given in the above figures. He is now engaged on similar research with adrenalin.

91. **Biologic Blood Test.**—Hauser's attempts to produce a powerful prepared serum for this test were so successful that the serum displayed such intense action that it agglutinated all kinds of blood to which it was applied. Consequently he warns that the purpose of the test is defeated if the serum is brought to such a high pitch of efficiency. Parallel tests with various kinds of blood should always be made at the same time. Microscopic examination of the blood should not be neglected, and can be made after the biologic test has been applied, using the sediment when the quantity of the blood is minimal. The reaction may be studied as it occurs in capillary tubes. He prefers a serum of a strength which renders the fluid turbid in less than half an hour, in the proportion of 1/30, while the other blood samples are still clear after six hours and show only traces of a flaky deposit by the end of twenty-four hours. He describes other technical points learned in his experience.

92. **Forensic Differentiation of Human and Animal Blood.**—Marx and Ehrnrooth suggest that the rapid agglutination

which follows when a foreign serum is added to a solution of human blood may prove useful for the differentiation of blood. When human serum is added to the blood the red corpuscles show very little if any effect, but when a foreign serum is added the red corpuscles become agglutinated in clumps nearly at once, and pile up with evidences of pronounced hemolysis. They proceed by dissolving the blood on an object glass with one or more drops of .6 per cent. salt solution to make a concentrated solution. They then draw a drop of blood from the finger tip and stir it into the dissolved blood. It is then examined under the microscope during the next fifteen minutes. In case of fresh blood the reaction occurs in a few seconds, but a few minutes may be required when the blood is several months old. They think that this method of differentiation will prove useful as a control test for the biologic method, or possibly substitute it.

93. **Prophylaxis of Ophthalmia Neonatorum.**—Dauber pleads for the compulsory use of the Credé instillations and the prompt notification of every case of eye affections in infants.

94. **Joint Formation as an Aid to Healing of Apical Lesions.**—Hofmann has examined 77 cadavers to corroborate Freund's statements in regard to the value of a movable joint in the cartilage of the first rib as a factor in the prevention and cure of pulmonary tuberculosis. Freund's communication was summarized in The Journal, xxxix, p. 170. He noticed that the first costal cartilage was exceptionally short and rigid in 30 cases of pronounced tuberculosis, while in the healed cases there was a movability amounting to an actual joint formation in some. He, therefore, suggested the severing of the first costal cartilage to give the lung more space, in cases of recurring apical affections. Hofmann's experience has confirmed these assertions, and he even goes beyond Freund in advocating the severing of the cartilage as a still earlier precaution, not waiting for the disease to progress to such lengths. He also states that the joint can be made as far along as at the junction of the cartilage and rib. The benefits of the chondrotomy are not restricted to abnormally short cartilages, but the operation is destined to aid in every case, as air and oxygen can reach the apex more freely, and the lung can expand better and aspirate larger quantities of blood into the apex.

101. **Blood in Rotheln.**—The blood was either quite normal or showed merely slight leucocytosis with mononuclear neutrophiles predominating, in the 4 children examined.

103. **Thyroid Treatment in Eclampsia.**—The success of thyroid treatment in the 2 cases reported completely confirms Nicholson's statements in regard to the efficacy of thyroid extract in this affection. Baldovsky found that the convulsions abated under its influence, while it also regulated the eliminating functions of the kidneys. The urine increased in quantity, and the proportion of albumin rapidly diminished. He used narcotics in combination with it, and recommends this practice as they keep the convulsions in check. His dosage was the same as Nicholson's, a .3 gm. tablet of thyroidin three or four times a day. The curves appended show the prompt benefit derived. The albumin nearly vanished in the first case within four hours of the second dose, which had been given two hours after the first one, dropping from more than 4 to a proportion of less than .5.

104. **Arrhenal in Malaria.**—Gautier's sodium cacodylate method of treating malaria has been found extremely effectual by Kavaleroff. He gives the particulars of 22 cases and states that it stands on the same plane as quinin, and possibly even surpasses it for certain cases. It is more effectual in recent infection.

112. **Addison's Disease.**—Scraps of skin contributed voluntarily by a young man suffering from Addison's disease were examined by Darkshevitch to determine the changes causing the pigmentation. The findings were not materially different from those observed in similar tissues in the cadaver. The pigment granules did not give the reaction for iron.

113. **Local Cocain Anesthesia.**—Krimoff reports that in both experimental research and the clinic much better results are obtained with pasteurized solutions of cocain than with those sterilized by boiling, and also with a 1 per cent. strength than with a stronger solution. He dissolves the cocain in sterile water and pours the fluid into glass tubes which are fused and then heated to 60 C. for three hours. In operating and in experiments on animals the anesthesia induced with cocain thus prepared lasted an hour or two, while twenty to thirty minutes was the limit with a solution sterilized by heating to 100 C., that is, boiled. He advocates local anesthesia as peculiarly adapted for herniotomies. He injects the cocain along the course of the incision, using six or seven syringefuls, and injecting from one-half to three-quarters of a syringeful at the point where the ileo-inguinalis nerve emerges, introducing

the needle deep into the tissue. He has thus operated on a number of cases of inguinal hernia with complete success, and no dread of the vomiting liable to follow chloroform. He analyzes the results obtained with various concentrations in 155 different operations. They demonstrate conclusively that cocain once boiled loses considerable of its anesthetizing power, and the anesthesia is much less durable than when a 1 per cent. solution is pasteurized, that is, kept at 60 C. (140 F.) for three hours.

115. **Fracture of Patella.**—Twelve cases are reported to demonstrate the advantages of suturing the bone, and to emphasize the fact that the final success of the intervention depends fully as much on the management after the operation as on the operation itself. By the tenth or twelfth day, if everything is proceeding favorably, the splint is removed and a lighter one is applied, reaching from the middle of the thigh to the middle of the leg, and the entire limb is subjected to systematic massage, with electricity if the condition of the muscles requires it. Passive movements should be commenced between the twentieth and thirtieth day, exclusively by the physician, and the patient then allowed to get up.

117. **Varicose Veins in the Army.**—Tentchinski concludes from extensive experience among the troops at Vladivostok that new recruits with even slight degrees of varicose veins in the legs should not be accepted for military service if the saphena magna is painful from this cause. Such a condition is liable to become acute and finally severe and chronic, necessitating the dismissal of the recruit. Even with the best of wills it is impossible for him to do military service during a severe attack. Another reason for rejection is that varicose veins are usually a sign of some constitutional affection or tendency to arteriosclerosis or neuritis. He believes that the saphena magna is first affected, the trouble being some disturbance in its valves. This not only reduces the functions of the limb but affords a predisposition to infectious processes. He operated on 21 patients, with a complete cure in 67 per cent. He describes considerable research likewise on the cadaver to better locate the saphena. He followed the Troyanoff-Trendelenburg technic.

120. **Uterine Cancer.**—Straukh operated on 5 patients by the Mackenrodt method, on 8 by the Wertheim, and on 7 by a method which is practically a combination of the other two. It aims to remove the lymphatic glands with the neoplasm more completely than is possible by other technics. He removes the growth through the vagina and cauterizes the raw surfaces with the Paquelin. The patient is then placed in the Trendelenburg position and the abdomen opened. The uterus is ablated and the posterior part of the vagina is sutured to the posterior sheet of the peritoneum. The latter is then drawn up on each side and careful search made for all glands, removing all the accessible ones, and concluding the intervention by drainage through the vagina. Three of the 20 patients died from septicemia and 2 from casual causes, but none in the group operated on by his method nearly two years ago. All are in good health to date.

121. **Floating Liver in Heart Disease.**—The congestion produced by a severe cardiac affection entailed secondary displacement of the liver in the case described. Stern thinks that the venous stasis in such cases is liable to still further displace an already abnormally movable liver, and is also able to render movable an otherwise normal liver. The movability of the liver is liable to have in turn an unfortunate influence on the heart. His patient was a man of 63, who had previously had three attacks of angina pectoris. The dragging of a heavily congested liver was evidently causing serious heart disturbances. There was resonance instead of dullness over the usual liver area, accompanied by severe, colicky pains and paroxysmal heart symptoms. The patient died with symptoms of disturbed cardiac compensation. Bruschini, he states, was the first to call attention to the mutual relations between heart disease and floating liver, reporting two cases of their coincidence and pointing out the connection between them.

124. **Biologic Blood Test.**—The value of this test is extolled by Diatroptoff, who mentions a recent forensic case in which its testimony was of decisive import. The judge and experts were taken to the laboratory and inspected the results of the tests half an hour after the specific serum had been added to the blood stains. He emphasizes, however, that after thirty hours bacterial action is liable to induce a turbidity which might prove misleading unless forewarned. If the tubes are to be kept for examination later he found that a drop or two of chloroform, added at the outset, prevented this bacterial action.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

THE DIETETICS OF ATONIC DILATATION OF THE STOMACH

BASED ON A STUDY OF THE PHYSIOLOGY OF GASTRIC MOVEMENTS.[*]

FENTON B. TURCK, M.D.

CHICAGO.

Food taken into the stomach is subjected to certain mechanical and physical forces derived from the energy of muscle contraction. The gastric movements result in a minute subdivision and final ejection of the stomach contents into the duodenum. Failure of the stomach to triturate and mix the food may be compensated for by chemical and other means, but if the expulsion of the contents is not accomplished, a most serious condition results that is paramount to every other consideration.

MUSCLE TONE.

The characteristics of unstriated muscle, of which gastric muscle is composed, present the phenomena of a peculiar functional activity called tone. Tone differs from the peristaltic or contraction waves, in that there is a condition of continued contraction or shortening which persists, more or less constantly, decreased or increased by varying conditions. The relation between the condition of muscle tone and changes occurring in ordinary contraction, such as peristaltic waves, is not yet thoroughly understood. The continued shortening or tone of unstriated muscle is considered to be under the control of the nerves. In animals, muscles, such as those of the claw of the crayfish, and the heart of the helix, possess the tonus independent of the nervous system. (Petrowsky.)

By the term tone or tonus we refer specifically to muscle tone, by which is meant that the muscle remains permanently short. The elongation or lax state of the stomach muscle allows a condition of what is termed clinically dilatation—lengthening of the muscle fibers. The function of peristaltic motion of the stomach is so inseparable from the phenomena of tonus of gastric muscle that the two conditions are usually considered together. Clinically, it is difficult to separate these factors until more definite physiologic relations are known. We have an example of two functions in the stomach during digestion, whereby we may observe with the *x*-ray the quiescent, tonic state of the cardiac portion, and the active peristaltic contraction of the pyloric end of the stomach, as shown by Cannon.[1]

THE CAUSE OF GASTRIC MOVEMENTS.

The stomach muscles are shaped into a subspherical hollow organ, which, during rhythmical contractions (peristaltic), materially alters its shape. The pyloric end (antrum pylori) approaches the cylindrical form during peristalsis, while the cardiac end retains more of its spherical form in a state of tonic contraction, giving the stomach a gourd-like appearance.

It was formerly thought (Beaumont and Brinton) that the entire organ was excited into a series of contractions during the digestive process, but it has been shown by numerous observers that only the pyloric end shows peristaltic action, while the cardiac end remains in a tonic and quiescent state. (Cannon, Hofmeister and Schutz, Moritz, von Mehring, Rossbach.[2])

To determine the results of the chemical action of food on gastric movements and those produced by different forms of mechanical stimulation, the author carried out a series of experiments on dogs, as well as on the human subject, As shown by the protocols at the end of this article, strong HCl, peptones, albumoses, starch, etc., showed no appreciable effect on the movements produced by these substances applied to the mucous membrane, while distention with air or water immediately excited increased peristalsis. If the air or water was under control, by forcing it into a bag within the stomach, so that all the air or water would return promptly, the resultant contractions were more numerous and vigorous. When vibratory exercise was used, the contractions were increased in proportion as the tension was increased. It would appear that tension is one of the most important factors in peristalsis of the stomach. The mechanical and physical factors become of greater importance in dietetics than the chemical action of food, especially in conditions of atony and diminished muscle contractions.

It was claimed by Brücke, chiefly on theoretic grounds, that the cause of the increased vigor and number of contractions at the end of the digestive process was due to the HCl, and this is taught by most physiologists to this day. But Hirsch[3] shows that water solutions of acid or alkalies pass out of the stomach independently of the reaction of the stomach contents.

Moritz[4] found the chemical substance of food has some effect on the time-expulsion of the contents. If very acid or alkaline, the contents remained longer.[5] Pawlow[6] has shown that when the acid-gastric contents reach the duodenum they cause by reflex action, a temporary closure of the pylorus.

---

[*] Read in a symposium on dietetics before the Chicago Medical Society, Jan. 20, 1904. This symposium was reported in THE JOURNAL, Jan. 30, 1904, p. 329.

[1] Cannon: Am. Jour. Physiol., 1898, vol. i; 1903, vol. ix, No. 6.

[2] Since writing this article I note that Lommel (Münchener medicinische Wochenschrift, 1903, i, No. 38) reports some recent observations of gastric movements in dogs similar to those made by Cannon. After feeding the trained dogs with chopped meat mixed with bismuth, rhythmical movements could be seen by the aid of the *x*-ray in two to six minutes, starting from the greater curvature; within five minutes the entire stomach took part. He shows, as Cannon reported, that psychic emotions influence the gastric movements.

[3] Hirsch: Centralbl. f. klin. Med., 1893, No. 4, 18.

[4] Verhandl. deutsch. Naturforscher und Aerzte, Vienna, 1894.

Chemical stimulation (alkaline or acid) may cause opening or closing of the pyloric orifice, as clinical experience indicates. The mechanical effects of tension on the muscle walls producing stomach movements seem most important.

MOVEMENTS OF ALL HOLLOW VISCERA THE RESULT OF TENSION.

In the observations that we make of the movements of other hollow *muscle viscera*, we note that similar factors enter into the causation of peristaltic contractions. According to Goltz,[7] the expulsion of urine is caused by the rise of pressure in the bladder; *with increasing tension* the contractions increase. It has been shown by von Zeissl[8] that with *increasing fluid causing increasing tension*, which in turn augments the force of each contraction, the pressure within the bladder is raised high enough to overcome the sphincter, and cause expulsion of the urine. Von Zeissl found that micturition occurred normally even after all nerve supply had been cut off from the bladder. The heart of a snail or the apex of a frog's heart, which is devoid of nervous ganglia, will contract rhythmically on distention with air or fluid.

THE UNIVERSAL STIMULANT OF PROTOPLASMIC MOTION.

Tension in one form or another *appears to be* the universal stimulant of protoplasmic motion. As Matthews and Whitcher[9] have shown in their experiments on the "Importance of Mechanical Shock in Protoplasmic Activity," however various the mechanical stimuli may be in influencing protoplasmic activity, they produce their effect by altering the state of the protoplasm. This change in state, however, is followed by definite metabolic structural changes, which must be *sufficiently abrupt to excite activity*. Meltzer[10] makes the unique suggestion: "But why not also assume that the great motility of the sperm is in every case an adequate mechanical shock appropriate *to start the normal cycle of cleavage* just as we see *that a simple mechanical shock* may be the means of setting up an artificial segmentation of the eggs of starfish."

The fundamental principles on which tension rests in the contraction of muscle have been carefully worked out by *Gad, Kaiser v. Kries*, and Schenck,[11] which show that the stimulus to muscle contraction is supplemented or re-enforced by second and repeated stimulation having its source in the tension which the resistance produces. Thus, as the muscle contracts against the load, it gathers energy from the resistance it meets. The resistance to motor power is of equal importance for the resulting movement and work.

Experimentally, we know that if a load is added to a muscle, the amount of work *it can then accomplish, within certain limits, is enormously increased*. Without a load, no work can be accomplished, though energy may be expended. By adding 30 grams of weight to a prepared muscle, the work accomplished leaps to 330 grammillimeters of work. Tension (lateral pressure) on the stomach wall excites the muscle to tonic contractions, and as the load decreases by the escape of the fluid portion of the stomach contents, it causes a marked increase in the force and number of the resulting contractions, which are observed at the end of the digestive period. The effect of tension under similar conditions is seen in the laboratory. When a muscle is connected with a strong spring or weight too heavy *to lift*, the muscle will contract without shortening. There will be energy expended, but no work accomplished. This is when *muscle is stimulated under what is known as isometric conditions*. If now the load be reduced so that the muscle can contract with shortening the resulting contractions show greater *vigor and accomplish* more work than the same muscle would if it had not previously met with a higher degree of resistance. The experiments recorded at the end of this report show *that tension produced by* stretching the gastric muscle by inflating the stomach with air causes a prompt response, and more powerful *contractions* follow when such stretching by inflation *is increased*.

An important difference between striated (voluntary) and unstriated (involuntary) muscle, as Fick has shown, is that the striated or *voluntary muscle* requires a comparatively slight degree of stimulation and of short duration, while the unstriated, such as stomach muscle, requires *a much more powerful* and longer duration of the stimulus to gain the greatest advantage. The resistance of the load to muscle contraction excites the liberation of energy, which, *as we have seen*, is necessary to accomplish work, but the duration of such stimulus must be of sufficient length of time to obtain the highest degree of contractions or peristaltic waves. In exhaustion, fatigue and atony, the same law exists, except that it requires within limits increased stimulation, and following the period of work a much longer period of *rest must be allowed for recovery* than under normal conditions.

THE RÔLE OF THE NERVOUS SYSTEM.

The question of the relation of the nervous system to the *gastric movements* has been the subject of a large amount of experimental investigation. Openchowski[12] looked on the nervous ganglion in the walls of the stomach as centers for the co-ordination of movements. The vagus has been looked *on as the motor* nerve of the stomach, and such observers as Longet, *Goltz, Bram*, Houckgeest, Openchowski and Morat have shown *that* movements occur after excitation of the cut ends of the vagus, but von Bram, Houckgeest and Morat observed such movements were dependent chiefly on the *stomach* being in a state of digestion. Langly[13] obtained variable results *after the administration of curare* and atropin.

Hlasko[14] *endeavored to locate the cranial center for* the movements of the stomach, and concluded *that* it lies in the corpora quadrigemina, and that probably the vomiting center is located in the same area, the fibers passing to the stomach along the spinal cord.

[5] Since writing this article I note that Meyer, working in Professor von Mering's clinic (Meyer: Ist die Entherung des Magens abhängig von dem Grad der Säurebildung? Archiv f. Verdauungskrankheiten, vol. ix, No. 6, 1903) presents experiments showing that the emptying of the *stomach contents* is in *proportion to the acidity. The contents are discharged* more quickly in deficient acidity and anacidity than under normal acidity, while in hyperacidity the reverse is the case.

Cannon has shown that anger, fear and other mental disturbances inhibited the movements of the stomach.

Schiff and Morat both concluded that rhythmical contractions were increased after stimulation of the splanchnic nerves.

Carion and Hallion[15] found that section of the vagus nerve is sufficient to produce complete atony and permanent dilatation of the stomach of the dog.

Pawlow and Katschkowski[16] have shown that cutting even both vagi nerves produces only a temporary disturbance of the gastric movements. "Indeed," asserts Pawlow, "the operation is consistent with long life and an excellent condition of health."

As to the gastric movements being operated by the nervous mechanism, the variableness of experimental results and the diversity of conclusions prevent us from assuming any positive position, except to admit the coordinating and regulating influence of the nervous system.

We may still conclude with Ewald:[17] "Yet all these experimental stimulations in mammals have an indefinite and uncertain character; their success is not great, and by no means constant."

THE MECHANICAL WORK OF THE STOMACH.

The mechanical work of the stomach may be divided into three stages: 1, Distention with food; 2, expulsion; 3, relaxation.

The normal resistance at the pyloric end of the stomach increases the tension (lateral pressure), which, within physiologic limits, increases the stimulus to more powerful and frequent contractions. At the end of the digestion we find the maximum degree of power and number of contractions. According to Frank,[18] increasing the resistance in front corresponds to increasing the load. The resistance is in proportion to the angle of the pyloric funnel and size of the aperture. The size, according to Dwight, of the normal human pyloric orifice, which is usually oval in shape, varies from 7x4 mm. up to 20x18 mm. The greater the resistance within certain limits, the greater must be the size and thickness of muscle. A definite amount of work is dependent on the size of the muscle.[19] In frogs, 1 c.c. of muscle is capable of 3 kilogrammeters of work, while 1 c.c. of human muscle is limited to 8 to 10 kilogrammeters of work, so that increased resistance demands not only increased size or volume, but better quality of muscle substance.

We find that muscle becomes hypertrophied in proportion as the work increases within certain limits and physiologic conditions. Whether the increased work be due to increase in the load within the stomach cavity, or the increased resistance in front, hypertrophy is the result. If the work passes beyond the physiologic limits, fatigue or atony and dilatation follow. Thus atony and dilatation may be found as the result of increased resistance in front, such as by stenosis of the pylorus, and cause prolonged overwork and exhaustion of the gastric muscle, or the overwork and exhaustion may be due to constant and excessive work on the load within the gastric cavity when no obstruction exists. Overwork and ultimate exhaustion are the result in either case, but the pathology of these conditions and the treatment are a different question.

I have shown[20] experimentally that prolonged intermittent tension of gastric muscle produces fatigue and dilatation of the stomach.

Ewald[21] has clinically observed that "atony of the stomach causes lengthened stay of food in the stomach. The distention of the stomach in turn paralyzes its muscle fibers."

From Penzolt,[22] von Mehring[23] and Moritz,[24] we learn the time required for the normal stomach to empty itself of the various classes and amounts of food and liquids. Penzolt found that digestibility of food is influenced much more by consistency than amount up to certain limits. The increased quantity taken does not proportionately increase the duration of the sojourn of the food in the stomach. Twice the amount of food taken at a time does not double the time required for digestion; six times the amount of original quantity (300 grams) of beef only required three times the original length of time before leaving the stomach; crackers quadrupled in quantity only required twice the time, and of liquids the quantity could be increased five times, with only double the time of the duration of the stay within the stomach. These empirical experiments were made on the healthy human stomach, but, as Riegel rightfully observed, "similar conditions are obtained in a dilated stomach." The explanation of these facts may be found in Fick's observations.

According to Fick,[25] if a muscle work against a heavy load, one-quarter of the liberated energy results in mechanical work, but if the weight be light, not more than one-twentieth of the energy is obtained as mechanical work. These facts correspond to the universal law of work and fatigue in all animals. The kind and degree of muscle work that produce fatigue vary in different muscles of the same animal. The power of the blood to preserve the irritability of muscle is seen in the experiments of Ludwig and Schmidt,[26] von Frey,[27] and H. N. Martin.[28]

THE FATIGUE OF GASTRIC MUSCLE.

I have shown (Loc. cit.) that fresh muscle serum neutralizes the toxic fatigue products of fatigued gastric muscle.[29] I have repeatedly shown by experiments and clinical experience that in fatigue or exhaustion of the stomach a much longer period of rest should be given than under normal conditions. If exhaustion is the result of increased resistance in front, as in stenosis of the pylorus, this rest can only be hoped for in the removal in one way or another of the obstruction.[30]

[29] The toxins of fatigue caused, as I have shown, antibodies to form. These facts are in agreement with the more recent experiments of Weichardt (Münch. med. Wochenschr., Jan. 5, 1904), on the skeletal muscles of mice and rabbits.

In other cases of atonic dilatation, a rational system of dietetics must be ordered; the pause for rest after the digestive period must be of sufficient duration for the stomach muscle to recover from the fatigue of each exertion. All the voluntary muscles are exercised by the daily activities of the body. Disturbances may arise from the abuse of muscle function, either by overwork or by lack of use. Food furnishes the normal exercise of gastric functions, and it is the abuses of the gastric function in one way or another that cause most of the pathologic results, one of the commonest disorders from infancy to old age. We may modify the term abuse in saying that what may be an error in quantity and character of food at one time may not be so under other conditions. Thus, after an acute disease, the greatest caution must be taken in the time, character and amount of the feeding.

DIETETIC MEASURES IN GASTRIC ATONY.

In the cycle of digestion there are a series of events: First, ingestion of food; second, the digestion and expulsion; third, the interval of rest. By the frequent small meal system in gastric myasthenia, the first event, namely, ingestion of food, impinges on the second and third events, or the second event (digestion and expulsion) lapses into the third event, which is the interval of rest, an important period in atonic dilatation. So long as food or remnants remain in the stomach, the gastric muscle is constantly excited by continued and fatiguing work. By giving a larger meal, but less frequently, the labor period is relatively shortened, while the interval of rest is prolonged. If one-half the quantity of food is given at one time, it does not lessen the digestive period one-half, as shown by Leube, Penzolt and others. In most instances a larger meal, varying within the limits, excites the gastric motor activity to increased peristalsis and more rapid expulsion of the stomach contents.

The value of a single meal daily not only allows rest for the fatigued organ, but serves as a recuperative means for the overworked secretory apparatus. Pawlow[31] shows experimentally that when food is prescribed in small quantities, at short intervals, it causes the oft recurrence of "appetite juice," which is so rich and strong, and when the whole ration has been eaten at once, there is an enormous drop in the formation of hydrochloric acid and ferment. Clinically, I have utilized this principle for years, and have proven its practical value in hyperchlorhydria with atonic dilatation. (See Cases 5 and 6.) The importance of the consistency and the physical effect of food are seen in giving a boiled starch mixture in cases of certain forms of atonic dilatation with hyperchlorhydria. (See Case 6.)

Usually two meals are ordered in the beginning of treatment—one in the morning and one in the evening. The composition, character and amount of food prescribed vary under various and peculiar conditions. The chief point to be aimed at is the consistency of the food, which should be semi-solid and finely divided, pleasant to the taste, a matter of great importance, as Pawlow has shown. By separating the meal-times more widely, we will often restore lost appetite, which is another very important factor of digestion. Where the appetite is excessive, a cracker and a little hot water just before the meal will often prevent the unnatural wolf appetite. Hot water is useful, as it passes in a shorter time from the stomach than cold water. In fact, one of the numerous causes, and not the least, of our American dyspepsia, is due to the large quantity of ice water drank at all times, on all occasions.

Many important problems in the dietetics of atony of the stomach must necessarily be omitted here. We shall consider the application of dietetics to the one condition of diminished, or loss of muscle tonus, and contraction, on which are dependent many associated symptoms. For example, if it is found in gastric myasthenia that 150 grams of meat, 200 grams of carbohydrates, 30 grams of fat and 300 c.c. of fluid escape from the stomach in eight hours, we must not conclude that we can immediately repeat the same amount, for the reason that a longer period of rest must supervene after the meal to allow sufficient time for the weakened muscle to recover from fatigue. The muscle will accomplish the work if the given rest period is sufficiently prolonged to enable it to recover from the exertion.

AUTOSTERILIZATION OF THE STOMACH.

Prolonged rest, however, not only allows the fatigued muscle to recuperate and regain energy, but also permits ample drainage, thus preventing bacterial growth. Bacteria do not flourish luxuriantly in the empty and clean stomach. Each time food is ingested before the remnants of the previous meal pass out of the stomach, the food is inoculated by growing bacteria developing in the remnants of previous meals. The stomach gains no opportunity to disinfect itself, which it may do in the empty and restful state. Complete recovery can not be expected when frequent, though small, meals are continued at short intervals throughout the day or into the night, as our text-books recommend.

To summarize: The two main pathologic conditions to be corrected in atonic dilatation of the stomach are: 1, The exhaustion of the gastric muscle; 2, the bacterial growth in the gastric cavity.

The length of time a given quantity of food remains in the stomach, and the appearance and chemical condition of the food mass after a given period of digestion, aids in the diagnosis and determination of the dietetics to be prescribed.

THE APPLICATION OF DIETETIC METHODS.

As previously stated, the main object is to correct by dietetics the muscle weakness. This is done not only for the nutrition of the patient, but to prevent bacterial growth and the resulting toxins, which produce many of the grave symptoms found in this serious malady. Nature here might teach us a lesson. When an acute attack of nausea and vomiting occurs, with total anorexia, enforced rest of the stomach is accomplished. So, with our therapeutic measures, it is often necessary to place the stomach in a state of complete rest, and administer all food by the rectum.[32] It may be necessary when giving food by the mouth to lessen the total amount and undernourish the patient. The gain here is twofold: First, the food that is taken is better digested; and, second, it is not robbed of its nutritive value by bacterial growth.

In beginning a course of dietetic treatment, after the stomach has been placed at rest, the question of the character, composition, preparation and time of giving food presents itself. A uniform diet for all the degrees and forms of atonic dilatation can not be arranged. Theoretically, a liquid diet would be most advantageous. Practically, it is better to give finely divided solid food, properly prepared, with appropriate amount of liquid, sufficient to aid the stomach to macerate the mass and inject it into the intestines.

---

[30] Riegel (Diseases of the Stomach. Am. Trans., Philadelphia, 1003, p. 385) says: "In one case we may be dealing with an absolute primary loss of muscle power; then we speak of atony. In another case the muscular power may be abnormally increased; there may be even hypertonicity, but the amount of work to be done is so large that even this increased muscle power becomes insufficient."

[31] Pawlow: Loc. cit., p. 136.

[32] Rössler: Wien. klin. Woch., 1893, No. 30.

If 3,000 calories are required of a mixed diet under normal conditions, it may be necessary in the beginning to cut this down to as low as 1,000 calories. For example:

100 grams breast of chicken finely ground.
100 grams mashed potatoes.
100 grams toasted bread.
30 grams butter.
300 c.c. hot, rich milk, which is first coagulated with rennet, in order that it may not coagulate in the stomach; then shaken back to liquid and heated.

The above furnishes about 1,000 calories, and may be taken in one meal, and the patient instructed to lie down on his right side for two hours. No more food is allowed until the following day. Water may be given by the rectum. In some cases it may be necessary to give, in addition, rectal feeding; often this is a disadvantage. Many of these patients have complete anorexia, and only forced feeding will restore the appetite and gain the necessary exercise for the stomach muscles and resulting nutrition. The following method has been of considerable advantage: One hundred grains of meat are first ground and placed in water for a few hours. The extractives are pressed out by a meat press and discarded; part of the albumin is lost, but this can be made up. Discarding the extractives lessens the irritation of a meat diet; 300 c.c. of milk are coagulated with rennet and shaken up to a liquid state and heated. Crackers are pulverized; one or two hard-boiled eggs are finely grated; bran is added sufficiently for "ballast." This is placed in a wide-mouthed bottle and thoroughly shaken. A cork is tightly fitted with two glass tubes, a rubber atomizer bulb is attached to one of the glass tubes, the other fits into the stomach tube, and the food is forced into the stomach by air pressure, which also keeps the glass tube from becoming plugged. Thus solid food can be given. Weak, jaded patients with complete anorexia and apparently no digestive energy, endeavoring to exist on the spoonful system of diet frequently exhibited, will by this method of forced feeding begin at once to show a desire for food. The exercise of the stomach brings about restoration of the digestive functions, and the patient soon begins to take his food independently with a relish.

Paradoxical as it may appear, a small quantity of food, as an Ewald test breakfast, will remain longer in the stomach of a patient with atonic dilatation and show less peristaltic activity than a large Leube test dinner. Clinically, it is frequently noted that a patient suffering from atonic dilatation of the stomach taking very small, but frequent, meals (either because so instructed or from fear of distress) will indulge in a comparatively large meal, followed by less degree of retention, with general improvement of the digestive activity.

In all cases with any marked degree of atony of the stomach, the patient must be strictly instructed to lie down after meals. Lying down for a time after a meal relieves the congested vessels, as the abdominal veins are devoid of valves.

In these cases of atonic distention of the stomach, the physiologic hyperemia during digestion becomes a pathologic congestion of the splanchnic vessels. The circulatory changes on distending the stomach are well recognized. The degree of these changes is shown in some recent experiments on the splanchnic circulation.[33] Lying down not only relieves the vessels, but also the muscle walls of the stomach, and by turning to the right side the ingesta shifts into the antrum pylori, which, as before stated, is the active mechanical portion of the stomach.

Von Mehring[34] has recently shown by experiments that lying down on the right side causes a more rapid emptying of the stomach.

The following cases are of interest, as examples of practical results obtained:

Case 1.—Dr. M., suffering from atrophy of gastric glands, motor insufficiency and dilatation of the antrum pylori. He had been in the habit of taking small and frequent meals, as he thought it gave more comfort. He was ordered two meals a day, one in the morning and one in the evening, gradually increasing to a liberal quantity. This resulted in great improvement. The motor power was restored to normal. The glandular condition remained the same. Several years have elapsed since treatment, but condition of the patient remains good.

Case 2.—Dr. W., atrophy of stomach, supposed to be carcinoma. Motor power very weak; marked retention. Frequent meals had been ordered. Result, emaciation and general decline. Treatment consisted of, first, one meal daily; afterward this was increased to two meals daily. The stomach, which had failed to respond to the smaller meals, was stimulated by the large ones.

Case 3.—C. Z., suffered from atrophy and atonic dilatation, with great emaciation and toxemia, the latter probably resulting from the dilatation and not from the atrophy. He had been taking small and frequent meals. By increasing the quantity and at the same time the interval between meals the condition rapidly improved. No return of glandular secretion, but motor power was restored.

Recent examinations and reports from the above cases show continued improvement under this diet system. The following case will illustrate a condition which I have repeatedly noticed:

Case 4.—A Southern woman, Mrs. M., wife of a physician, suffering with great weakness and emaciation, was bedridden as the result of chronic atonic dilatation of the stomach. Free HCl absent. Small and frequent meals had been administered with the usual line of treatment, as is customary in these cases. On examination, the stomach was enormously dilated, and the gastric wall in an advanced state of atony. A small Ewald test meal remained in the stomach twenty-four hours. A large meal of finely divided meat, mashed potatoes and bread and butter passed out of the stomach in ten hours. A single large meal was given once daily until the stomach gradually regained its tone; after this a small quantity of food would stimulate the muscle movements sufficiently to entirely empty the stomach.

The following are cases of hyperchlorhydria and atonic dilatation:

Case 5.—Mr. D., aged 48, suffered for years with atonic dilatation of the stomach with a high degree of hyperchlorhydria and supersecretion. He was incapacitated for any kind of business, which he had given up for two years, and had all the usual treatments for such condition—lavage, electricity, baths, springs, drugs and travel. At last, operation was the only hope offered, which he refused. On examination five years ago remnants of food, albumoses and free hydrochloric acid were found in the stomach twenty-four hours after ingestion. He was placed under treatment. Only 340 meals were allowed in 340 days, one meal a day. Complete restoration followed. The hyperchlorhydria and supersecretion disappeared with the atonic dilatation. Recent examination proves a permanent result. He now takes two meals a day, one in the morning and one at night.

---

[33] Proc. Am. Gastro-Enterolog. Assn., 1900; Am. Therapist, November, 1900.

[34] Von Mehring: Therap. d. Gegenwart, No. 5, 1902.

Case 6.—A young man, aged 23, Mr. T. F., manifested every symptom of complete pyloric stenosis; great pain, vomiting and absolute weakness; emaciation. Frequent small meals of meat juice, peptones, rice, eggs, milk and most patent food preparations. Examination showed a high degree of atonic dilatation, with .35 per cent. free HCl. Retention of food four days; complete stagnation. The stomach was placed at complete rest for two days. First feeding, liquid corn starch boiled; four teaspoonfuls of the corn flour to 600 c.c. of water, sweetened and flavored. Next day repeated. Gradually increased quantity of starch; two meals a day, adding gradually macaroni, eggs, milk (first coagulated), and, finally, mixed diet. Result in ten days showed marked retraction of the dilated stomach, which emptied itself in six hours.

PHYSICAL METHODS ASSOCIATED WITH DIETETIC TREATMENT.

In connection with diet, certain mechanical methods of treatment are not only useful, but often indispensable. For the mechanical effects, lavage is recommended by most of the text-books, and added to this galvanic and faradic electricity, general baths, exercise and drugs. A large share of the patients I have treated in the last ten years had all these methods used, without success, often with harmful results. I have presented many of this class of patients, after a course of treatment, before this society on several occasions.[35] The objections to lavage have also been shown. While lavage has its use, in complete stagnation, as a palliative measure, those methods are most valuable, as I have frequently demonstrated, that can mechanically affect the gastric muscle directly, without washing out the necessary nutriment and secretion from the stomach cavity. Riegel seems to have obtained but little benefit from the use of static, galvanic or faradic electricity. I have found high frequency with the Oudin resonator of considerable benefit as an adjuvant.

CONCLUSION.

Physical and mechanical disturbances of digestion require that more attention be paid to the physical and mechanical effects of dietetics on the physiology of the gastric muscle.

EXPERIMENTS.

1. Method of determining the effect on the muscle movements of the stomach of dogs with various classes of food, gastric secretion, and the products of digestion when applied to the mucous membrane of the stomach.
2. The effect of tension on gastric movements.

The control dogs fasted for twenty-four hours. The abdomens were opened and covered with a very thin rubber diaphragm stretched across a frame to prevent evaporation. The surrounding area was kept warm. The spontaneous movements could be readily observed through the rubber diaphragm. The movements were noted as to the number of peristaltic waves, degree of contraction, length of each contraction, and time. The movements usually occurred not more than a minute apart; occasionally one every thirty seconds; frequently a pause of two or three minutes. They were characteristically weak and sluggish; many of the waves barely noticeable. Whenever the air was allowed to reach the abdominal cavity, movements were excited. The movements were restricted to the pyloric end of the stomach. The dogs used in the experiments were prepared in the same manner as the control dog, and placed side by side to observe any differences in the movements of the stomach. Injection of the substances used was accomplished with a piston syringe attached to a small needle douche, so that the fine jets or streams were projected against the mucous walls of both the pyloric and cardiac ends of the stomach.

Series 1.—Twenty c.c. of the solution or mixture of the following substances were injected into dogs' fasting stomachs; time of each observation, twenty minutes.

1. Filtered stomach contents withdrawn from a dog's stomach three hours after meat and bread.
2. HCl, .1, .2, 5 per cent. solution.
3. Pepsin, 1 gram.
4. Peptone, 2 grams.
5. Starch mixture.
6. Sugar, two grams.
7. Alcohol, 25 per cent.
8. Water.
9. Strong bouillon.

The above caused no increase in number or force of contractions. The following caused slight increase in number of contractions.

10. Tincture capsici, gtt. 3.
11. Mustard oil, gtt. 2.
12. Oil of cloves, gtt. 3.

The same substances were injected into dogs' fasting stomachs one hour before opening abdomen. No increase in number or force of contractions, as compared with the control.

Series 2.—Mechanical effects of tension.—1. In the first experiment, 300 c.c. water, at a temperature of 38 C., were introduced into the stomach, causing increased peristalsis.

2. Then 500 c.c. water, at 38 C., introduced into stomach, also caused increased peristalsis. On the water being allowed to return, the movements were markedly increased.

3. Water, 500 c.c. at 38 C., was introduced into a bag in the stomach, attached to a double stomach tube; movements were increased. The water was allowed to flow out and the peristaltic waves increased in number and frequency.

4. The temperature of the water was increased to 50 C.; this increased the muscle contractions.

5. Air was forced into the bag. One outlet of the double tube was attached to a manometer, the other to a compressed air tank. When the tension was raised to 10 mm., after a pause, the movements became more vigorous. After the air was allowed to escape, the peristaltic waves increased in number.

6. Repeated introduction of air and allowing it to escape was continued for five minutes, causing very vigorous movements.

7. Increasing the tension up to 30 mm., and allowing the air to escape slowly, caused rapid peristalsis, one wave every one or two seconds. The antrum pylori appeared like a corrugated tube. Ring-like movements confined to the pyloric region. Some waves were noted in the cardiac region, but no constriction. After repeated vigorous exercise, apparent antiperistaltic waves were noted.

8. Heating the air by passing it through water at a temperature of 70 C. increased the force and number of contractions.

---

9. Passing CO_2 through the stomach with the double tube caused increase in the movements in proportion as the pressure was increased.

10. Introducing the vibratory apparatus into the stomach caused a "shattering" of the gastric muscle and increased peristalsis.

THE MATHEMATICS OF THE DIABETIC DIET.*

ALFRED C. CROFTAN, M.D.
CHICAGO.

There is a popular prejudice to the effect that glycosuria calls for complete withdrawal of carbohydrates. This is occasionally good practice. In the majority of cases, however, it is superfluous, and imposes unnecessary hardship on the sufferer; and in many cases it is decidedly bad practice and dangerous. This routine treatment is to be condemned on two grounds chiefly, viz., (1) because it is almost impossible to adequately nourish these patients unless the carbohydrate is replaced, bulk for bulk, by other food equivalents; (2) because the complete withdrawal of the carbohydrates eminently favors the development of acidosis, and incidentally precipitates the almost inevitable consequence of acidosis, viz., diabetic coma. I venture to say that failure to mathematically regulate the nutrition of sufferers from diabetes, in innumerable cases leads to death from slow starvation, and that complete and injudicious withdrawal of the carbohydrate elements of the food precipitates the development of coma in many cases where it could well be prevented.

In order to fully appreciate the beautiful accuracy that can be adopted in feeding diabetics, it is necessary to appreciate the significance of the laws of nutrition, as we understand them to-day. Basing on the knowledge of metabolism that has been evolved from latter-day researches in physiologic chemistry, we can almost mathematically regulate the diet in diabetes. The gratifying results obtained from this practice fully justify the pains that must be expended in studying the problem carefully in each case that comes under observation.

THE MAINTENANCE OF GENERAL NUTRITION IN DIABETES.

For measuring the nutritive value of the different classes of foods, the term "caloric" has been imported from the realm of physics. A calorie is that amount of heat that is needed to raise the temperature of 1 kilo of water 1 degree (Celsius). Each article of food, it has been found, in process of metabolism (i. e., of assimilation, oxidative disassimilation and elimination) in the body generates a definite quantity of heat, or the mechanical equivalent of this heat in labor. Expressed in calories:

1 gr. of proteid furnishes	4.1 cal.
1 gr. of carbohydrate furnishes	4.1 cal.
1 gr. of fat furnishes	9.3 cal.

It has further been determined that a normal adult requires from 30 to 35 calories a day per kilo of body weight, and that these calories can be furnished by any one or all of the three classes of food vicariously. If this caloric value is not supplied, the body must consume its own tissues, and as a result emaciates.

In the case of diabetes, with the loss of valuable unconsumed sugar in the urine, the average diet does not furnish sufficient caloric value, as may be seen from the following example that I quote from my case book:

Case 21.—Mrs. W. P. Weight 60 kilo. Calories required for adequate nutrition, 60×35=2100.

Average diet on six successive days:

Proteids	150 g. x 4.1 =	615.0 cal.
Carbohydrates	190 g. x 4.1 =	779.0 cal.
Fat	110 g. x 9.3 =	1023.0 cal.
		2417.0 cal.
Average daily sugar excretion	160 g., x 4.1 =	656.0 cal.
Resulting food value only	=	1761.0 cal.

Instead of receiving, therefore, the full caloric value required, i. e., 2100 cal., the patient, owing to the loss of sugar, only received 1761.0 cal., although the diet represents 2417.0 cal. This represents a deficit of 2100—1761=339 cal. And these deficient calories must be supplied from the destruction of the patient's proper tissues.

One can further readily calculate what proportion of this deficit is made good from the albumin of the patient's tissues, which from the fat, and the diet can be regulated accordingly. All one has to do is to determine the output of nitrogen in the urine and feces, and compare it with the nitrogen intake (food nitrogen).

This patient, for instance, received in the daily diet 150 g. of albumin, and as albumin contains 16 per cent. of nitrogen, this amount contained 24.0 g. of nitrogen. On this diet the patient excreted a daily average of 23.7 g. of N. in the urine, and of 3.1 g. of N. in the feces, making the total N. output 23.7+3.1=26.8 g. of N.

The N. output, therefore, is greater by 2.8 g. (26.8—24) than the N. intake, and this excess must have been derived from the patient's own albumin. As 2.8 g. of N. are contained in 17.5 g. of albumin ($\frac{2.8\times 100}{16}=17.5$) and 17.5 g. of albumin can produce 71.75 calories (17.5×4.1=71.75), there remain only 268.25 (339—71.75=268.25) of the 339 deficient calories to be accounted for. As these must be derived from the patient's fat, one can readily determine by dividing 268.25 by 9.3 (the caloric value of one grain of fat) that 28.8 g. of the patient's fat were consumed.

The patient, therefore, on a diet valued at 2417 calories, i. e., considerably more than the calculated value necessary to nourish a normal subject of 60 kilo (2100 cal.), lost 17.5 g. of her own albumin and 28.8 g. of her own fat.

Hence the polyphagia that is so common in this disease. The patients eat as much as a normal subject, but the diet does not adequately nourish them. "Stomach hunger" may be appeased, because the stomach is filled, but "tissue hunger" soon appears. This hunger only disappears when the meat and fat are increased.

THE BOUNDARY OF SUGAR ASSIMILATION IN DIABETES.

If it were absolutely true that diabetics could use none of the sugar that enters the blood stream, the question of feeding would be theoretically a very simple one. viz., one would have to exclude carbohydrates and replace them by meats and fats of sufficient caloric value to make up the caloric deficit.

As a matter of fact. this is not the case. Only a small minority of cases are altogether unable to utilize any of the sugar. These are the very grave cases that are, fortunately, rare, and would be still less frequent if many milder cases were not transformed into grave cases by injudicious dieting. In these patients it may be necessary to withdraw all carbohydrates for a time, but the almost inevitable result of this practice, as I will presently show, is the dreaded development of acidosis and death from coma. In the great majority of cases the patients can utilize some of the sugar, and it is absolutely bad practice to withhold this food permanently; it is equally bad practice, however, to give such cases too much sugar, for this is apt, by overtaxing of the sugar-destroying function, to "fatigue" this function and to lead to increased inability on the part of the body to utilize sugar. It is necessary, therefore, in each case, to determine the exact tolerance of the body, the so-called boundary of assimilation, and to feed the patients accordingly.

---

* Read in a symposium on dietetics before the Chicago Medical Society, Jan. 20, 1904. For the other papers see The Journal, Jan. 30, p. 329.

This is done as follows: One must remember that the normal body can destroy very large quantities of sugar (and other carbohydrates). The source of this sugar is twofold. One part comes from the food; the second from the tissues of the body, chiefly the albumins, the latter, as is well known, splitting off sugar molecules in process of intracellular degeneration. Immaterial whence the sugar is derived, a portion is burned up at once, a part is stored as glycogen in the liver, muscles, glands and working organs of the organism, and a part is finally converted into fat and stored. Occasionally too much sugar enters the blood from without (but this event is rare and requires colossal quantity), so that all the sugar reservoirs become filled. Then the percentage of sugar in the blood increases abnormally (hyperglycemia) and some of the sugar is wasted in the urine (alimentary glycosuria). The same event, i. e., hyperglycemia followed by glycosuria, occurs if the powers of the organism to destroy the normal amount of sugar or to store it as glycogen or fat become insufficient. For it is clear that if less sugar than normal is destroyed or stored, it must also accumulate in the blood and appear in the urine. The latter condition obtains in diabetes.

THE THREE DEGREES OF DIABETIC GLYCOSURIA.

It is conventional to distinguish several degrees of diabetic glycosuria that vary in degree but not in kind. In the mildest kind all the sugar disappears from the urine in a few days if the carbohydrates of the food are withheld. In such cases the addition of small quantities of carbohydrate to the diet may not even cause glycosuria; as soon as more than a certain quantity (less, however, than the amount required to produce alimentary glycosuria in a normal subject) is given, sugar invariably appears in the urine. In some of the cases, further, no sugar appears if a considerable quantity of carbohydrate is given in small, divided doses, whereas the ingestion of the same quantity at once is followed by glycosuria. In these cases, then, the power to destroy sugar is by no means completely lost; for even when we withdraw all carbohydrates from the food, a certain amount of sugar (as stated in a previous paragraph) nevertheless enters the blood stream "from within," i. e., from the degradation of the circulating and organized albumin molecules that split off a sugar group. This sugar the organism can completely utilize in the mild form, and in addition it can utilize a certain portion of the food sugar.

In the severe form of diabetic glycosuria, we encounter altogether different conditions. Here the sugar never disappears completely from the urine, even if all carbohydrates are withheld for days or weeks. This indicates that not even the sugar that is derived from the intracellular disassimilation of albumin, and from the disassimilation of the food albumin, can be utilized. In extreme cases, even complete withdrawal of all food does not stop the sugar excretion, indicating that even the small quantities of sugar derived from the destruction of the patient's proper albuminous tissues are only incompletely utilized.

In still other cases, the carbohydrates must be excluded from the diet and the albumin considerably reduced before the glycosuria is inhibited. These cases properly constitute a third group, i. e., diabetic glycosuria of medium severity. The boundaries of this group are not clearly defined, and many transition forms between it and the mild cases on the one hand, the severe cases on the other, can be arranged. With proper dieting, cases of medium severity can usually be converted into the mild type; with improper dieting, they almost invariably develop into the severe type.

To summarize: One may speak of the mild form of glycosuria if the sugar excretion stops at once after withdrawal of carbohydrates, if it does not reappear when small quantities of carbohydrates are administered, and if at no time the amount of food albumin need be reduced.

One may speak of the medium form if not only the carbohydrates must be withdrawn completely before sugar excretion ceases, but the food albumin must also be reduced to such a point that less than 18 g. but more than 10 g. of N. appear in the urine.

One may speak of the severe form if, in order to stop the glycosuria, the carbohydrates must be stopped, and in addition so much albumin must be withdrawn that less than 10 g. of N. appear in the urine. Cases in which even this deprivation of food fails to reduce the glycosuria are, of course, also to be included under the severe form.

DETERMINATION OF THE DEGREE OF GLYCOSURIA.

A popular method for determining the degree of glycosuria is the following: The patient is given what may be called the "diabetic test meal." This consists of a carbohydrate-free portion and a weighed portion of some carbohydrate food. The former may be composed of meats (about 350 g.), eggs, cream, cheese, spinach, asparagus, salad with oil dressing, meat broths, tea, coffee, claret. The latter consists of 100 g. of white bread, preferably administered in two portions of 50 g. each, in the forenoon and afternoon. At times it may be necessary to administer other carbohydrate food instead of white bread, because it may be of practical importance to determine the tolerance of the organism for other starchy foods and for the different sugars.

If the patient on this diet (carbohydrate-free meal +100 g. of white bread) excretes no sugar, then we are dealing with a very mild form of glycosuria; the amount of bread should then very gradually be increased on successive days until sugar finally appears in the urine. Thus, if the patient on one day excretes no sugar after eating 3×50 g.=150 g. of bread, and on the next day passes sugar on 4×50=200 g. of bread, then the "boundary of assimilation" (see above) lies between 150 and 200 g. of white bread.

If the patient excretes sugar on the test diet, then we are dealing either with the mild or the medium form. If after withdrawal of the 100 g. of bread the glycosuria stops, then it is a mild form. If the sugar secretion still persists, then the case is medium or severe. The food albumin must now be reduced. If the glycosuria stops after the albumin is reduced to such a point that less than 18 g. of N. appear in the urine, then the case is one of medium severity. If the albumin must be reduced so much that less than 10 g. of N. appear in the urine, or if it does not stop after the withdrawal of all food, then we are dealing with a case of severe diabetic glycosuria.

I need hardly emphasize that one single determination of this kind is of little value in so chronic a disease as diabetes; consequently the above tests should be performed several times during the year. Only in this way can the success of the dietetic treatment instituted on the basis of such tests be gauged. One must, moreover, never forget that incalculable fluctuations in the sugar excretion and in the tolerance of these patients for sugar occur in nearly all the cases, and that a single determination of the boundary of assimilation may hence lead to wrong conclusions.

PRACTICAL DIETETICS BASED ON THE ABOVE PRINCIPLES.

Within the narrow scope of this article, only the broad principles underlying the feeding of diabetics can be declared. The fundamental postulate is to maintain the patient's nutrition, and this is essentially synonymous with maintaining what is called "the nitrogen equilibrium"; i. e., the N. output must never exceed the N. intake; in other words, the albumin content of the patient must be jealously maintained. The patient, therefore, must receive food that. after the deduction of the sugar wasted in the urine, allows him to utilize at least 35 calories per kilo of body weight *pro die.*

The amount of carbohydrate permitted must be determined according to the methods described above, i. e., the boundary of assimilation must be established. Theoretically, this is a very simple matter. The physiologic chemist may be guided exclusively by the results of these tests. The physician should, however, take into consideration certain clinical aspects of the question that may induce him to modify according to his best judgment the mathematical conclusions that are forced on him.

Thus, on the one hand, it may become necessary to reduce the carbohydrates considerably below the established boundary of assimilation. or even to exclude them altogether for a time, if it is found that the tolerance of the patient is growing less; if this precaution is not observed, the mild form may be rapidly transformed into a severe one. One may say axiomatically that the reduction of the carbohydrates considerably below the tolerance of the patient, places the sugar-destroying function at rest and thus enables it to regain its old power, and that inversely, crowding of the carbohydrates to the limit of tolerance engenders fatigue of the already impaired function, and hence reduces the tolerance of the organism for sugar. In addition, we know from experience that the reduction or withdrawal of the carbohydrates greatly aids in combating certain complications that may endanger the life of the patient. Occasionally these only yield if carbohydrates are withdrawn or reduced to a minimum for a time. I refer, e. g., to furunculosis, pruritus, neuralgias, retinitis, etc.

On the other hand, it may occasionally be good practice to give more carbohydrates than the mathematical tests indicate. The removal of the glycosuria is not the only aim, for the excretion of sugar is, after all, merely a symptom. True, it is our chief index of the progress or regress of the disease, and the loss of sugar constitutes the chief danger to the patient. Nevertheless, the loss of some sugar in the urine may occasionally be less dangerous to the patient than the withdrawal of all carbohydrate from the food. Rather prolong the patient's life, even though glycosuria persists, than stop the glycosuria and incidentally hasten the patient's death.

Two reasons chiefly should induce us to give carbohydrates to patients with glycosuria, even at the risk of increasing the excretion of sugar, viz.: (1) The impossibility of adequately nourishing most patients on a meat-fat diet alone; (2) the increased danger of acidosis and coma incident to the withdrawal of all carbohydrate.

A meat-fat diet would soon become utterly disgusting to a well person, and he could ill tolerate the withdrawal of carbohydrate. A diabetic, moreover, has an abnormal craving for carbohydrates, particularly bread.

Albuminous foods alone can not be given in sufficient quantities to furnish enough calories. The addition of fat may make up the deficit, but it is a peculiar fact that one can eat much more fat with relish if some carbohydrate is given. than without it; here also alcohol with its 7 calories per gram often helps out. If the patients do not relish their food, the normal psychic stimulus so necessary to normal gastro-intestinal digestion is sacrificed; the poor appetite induces the sufferer to eat too little; the perverted gastro-intestinal secretions only inadequately prepare the food for assimilation, and the inevitable result is starvation, and the development of the manifold complications incident to malnutrition.

As far as the development of acidosis finally is concerned, we know that a certain amount of carbohydrate is necessary to promote the oxidation of the members of the acetone group (oxybutyric acid, diacetic acid and acetone) that escape destruction and thus accumulate in diabetics. If all carbohydrate is permanently withdrawn, this oxidation is particularly difficult. It is a well-known fact that in diabetics the administration of a little carbohydrate will greatly reduce the acetone excretion and will often cause the rapid disappearance of oxybutyric acid and diacetic acid from the urine. Hence, in acidosis and impending coma, the administration of carbohydrates, if necessary dextrose per rectum or levulose intravenously, is good practice; and in the same sense the occasional administration of moderate quantities of carbohydrate pabulum is good preventive treatment.

The practical execution of the dietetic treatment of diabetes has only barely been touched. It is clear that much can be done for these patients, provided each case is studied with the accuracy of a metabolic experiment. The "busy practitioner" may argue that he has not the time to perform all these determinations. That may be true, but then he should not undertake to treat diabetes. Properly speaking—and the plan is gaining widespread and deserved popularity [illegible] should be treated in an institution, or should at least from time to time undergo a few weeks' observation and treatment in a hospital, where his case can be studied as outlined above.

I make an earnest plea for more careful, more mathematical regulation of the diet in this class of sufferers, and I emphatically decry the slovenly, the criminal routine habit so universally adopted in this country. of handing every patient with sugar in his urine a diet-list on which is found printed a list of articles that contain no carbohydrates.

THE RELATION OF NATURE'S PROVISION FOR HEART STIMULATION AND CONTROL TO THE USE OF CARDIAC DRUGS IN ACUTE DISEASE.

LOUIS FAUGERES BISHOP, A.M., M.D.
Physician to the Lincoln Hospital.
NEW YORK CITY.

Before plunging into the indiscriminate use of drugs which have the property of causing the heart to beat more strongly, it is well to consider what provision has already been made in the same direction by the body itself. and also what is the precise object of such intervention in a particular case.

The heart is wonderfully responsive to the demands of the body when subject to exertion or disease. In acute conditions, stimulation *in the sense of urging the heart* to expend more energy is seldom demanded except in sudden emergencies. Fever is a great heart stimulant, as is also inflammation.

The use of the term "heart stimulants" in reference to drugs that are used in the course of disease with the idea of assisting the heart and preventing the failure of its powers when they may be most needed, is a crude employment of words and has led to much misconception. Who would think of whipping a horse that was already struggling under an unusual load, or further opening the throttle of an engine when it was going too fast?

The fact is that we have but a few heart stimulants in the true sense of the word, and we hardly ever use these. The only time when drugs are used with the direct purpose of stimulating the heart is in sudden emergencies. Then we avail ourselves of the fact that many drugs which are useful as heart regulators also possess the property of temporarily stimulating the heart. The best heart stimulants, however, such as ammonia, ether and nitrite of amyl, are poor regulators, and the best regulators, such as digitalis, strophanthus and iodid of soda, are poor stimulants when quick action is needed.

The whole question of heart stimulation needs revision in its clinical aspect. A good beginning could be made if the term stimulant were dropped entirely and the idea of regulation substituted. A hundred lives are saved by the judicious control of the overstimulation which results from disease where one is saved by direct stimulation as such. The only excuse for the use of heart stimulants is that they have been misnamed and are useful as regulators.

The misconception of the importance of stimulation as an element in recovery from disease has unquestionably led to much harm. When in a very sick person it is found that the pulse is slow, reflecting only the weakness of the patient, one should rather rejoice than otherwise. Circulatory failure does not, as a rule, take place in *this direction. Primary* low arterial tension without excessive rapidity is not ordinarily dangerous if let alone. Such a heart may carry on its work successfully, while if injudiciously drugged, it may be so exhausted that if the stage of the rapid and feeble heart be reached, there may not be reserve force enough to carry the patient through the disease. I have repeatedly seen cases in which, on account of simple feebleness of the pulse in acute disease, the patient had been drugged beyond measure, with the result that the heart and pulse were showing most erratic action, but in which, the occasion for the original stimulation having passed, the withdrawal of all drugs soon restored the heart action and pulse to normal.

Failure of the heart most frequently takes place in the direction of increased rapidity. This is probably due to the failure of a very radical element in the living organism known as inhibition. In connection with the heart, *the nerves which conduct this impulse from the* great nerve centers which seem to be the center of life, are well known. The same influence in one form or another affects every organ and tissue of the body. On it depends co-ordination in every vital process. An instance of its failure to act is seen in increased patellar reflex, due to cutting of the path of connection between the brain and the muscles of the thigh.

So increase in rapidity of the heart in disease tending to dissolution is a very radical thing, and is only *successfully combated by measures influencing* vitality itself, such as improved nutrition of the whole body, improvement of the nervous system at large, and the removal of those things which are acting contrary to the interests of the whole physical economy. I can remember, as a medical student, bringing to bear, when opportunity afforded, every known heart drug in the attempt to control the rapid and feeble heart action of dying patients, and I could not understand at that time why so little was accomplished.

In acute disease, while there is life there is hope of the restoration of the patient to health, so that I strongly advocate the most strenuous efforts to the very last to avert the tendency to death; but there are certain limits beyond which drugs having a direct influence on the heart are no longer useful. If the patient is to be saved it must be done by the restoration of the inhibitory quality by measures directed to the restoration of the whole bodily economy, hence the value of strychnin, of hydrotherapeutics, of nutrition, and above all, of sleep and the removal of exhausting influences.

Interesting as they are and important, the consideration of the mechanics of the circulation must give way to the consideration of the patient himself as an individual. There is a trite saying that a man is as old as his arteries, and in acute disease it may be said, as a rule, that the heart is as good as the man.

The moral of it all is that in acute disease the question of cardiac drugs is a matter that must *not* be lightly considered. I would like to hear the views of other general practitioners on this important subject.

54 West Fifty-fifth Street.

OBSTRUCTION AND CONSEQUENT DISTENTION THE CAUSE OF APPENDICITIS,

AS PROVED BY CASES AND BY EXPERIMENTAL APPENDICITIS IN DOGS.

C. VAN ZWALENBURG, M.D.
RIVERSIDE, CAL.

We frequently find an obstructed and overdistended appendix, and the earlier in the attack the appendix is seen the more frequently is this condition observed. It is constantly mentioned by writers, and is by several connected with the production of gangrene, notably by Hartley,[1] Ochsner[2] and Hemmeter.[3] *Robert* Abbe[4] has made mention of this condition in connection with his study of stricture and recurring appendicitis. Dieulafoy[5] has said much about his theory of a closed sack and its effect in increasing the virulence of bacteria.

---

[1] Hartley, Frank: Dennis System of Surgery, 1896, vol. iv.

I fail to find, however, any reference to the resulting hydraulic pressure on the blood vessels of the mucosa and submucosa and the consequent blood stasis in the inner layers of the entire wall of the distended sack. This is to me the important missing link between constriction and infection, and the point toward which this paper is principally directed.

The appendix has a firm fibromuscular wall pierced by numerous blood vessels, which ramify the submucosa and are distributed to the mucosa. The muscular coats are circular and longitudinal, and no doubt actively contract and force material from the canal (Deaver). The cavity of the appendix usually contains fecal matter and always numerous bacteria.

The blood pressure in the veins is minus, in the capillaries from 4 to 6 mm. mercury, and in the arteries 90 to 160 mm. As soon as the hydraulic pressure within the appendix or any occluded portion exceeds 6 mm., there will be more or less capillary stasis. The higher this pressure climbs the more will the blood current be interfered with, until at 90 to 160 mm. evidently complete blood stasis must follow. In the presence of the normal bacteria of the appendix, this blood stasis will be speedily followed by infection and, if complete and permanent, by necrosis or gangrene.

The obstruction in the appendix may give way, the interference with the circulation be removed, and the progress of the infection arrested at any stage. This infection will vary in degree and character according to the amount of pressure, the length of time it continues and the virulence of the organisms present. That this occlusion may be temporary seems practically self-evident when we study the pliability of the plug and the distensibility of the constriction.

Various experiments have been made by Roux,[6] Beausenat,[7] Nicolayson[8] and others to produce appendicitis in animals. However, a careful search in the voluminous literature of the subject failed to bring to light any exposition of what my own cases had led me to consider the true cause of appendicitis, and the following experimentation was begun. Dogs were selected for the experiments because they are easily obtained and handled, and because their appendices more nearly resemble the human than do those of herbiverous animals. Most of the work was done at the Hendryx Laboratory in Los Angeles, which was placed at my disposal through the courtesy of Dr. Stanley P. Black, and I feel that whatever success has been achieved is in no small measure due to his kindly suggestions and encouragement. I am also under many obligations to Dr. E. L. Leonard for her readiness to assist and for her caring for the specimens.

EXPERIMENTS.

Experiment 1.—Medium sized dog. Ether. Aseptic abdominal section. The appendix was brought up out of the incision. A silk ligature was passed by a needle around the appendix at its junction with the colon in such a manner as to exclude the principal blood vessels from its grasp. This ligature was not placed so distinctly subperitoneally as was done in the succeeding experiments, but the results showed that the circulation of the appendix had not been interfered with by it. Before this ligature was tied, an aspirating needle was passed into the colon about 1 cm. proximal to the ligature and made to enter the appendix through its opening into the bowel until its point was well within the free cavity of the appendix. The ligature was now tied with one knot just tight enough to close the appendix at its "valve of Gerlach" about the needle. The needle being connected with a reservoir, a compression bulb and mercury manometer, ordinary tap water was forced into the appendix until the manometer registered 150 mm. The appendix held about 4 ounces before that point was reached. After holding the pressure at this point for a few minutes to make certain that distention was complete, the needle was withdrawn, while at the same time the ligature was drawn tight and double tied, retaining the water at a pressure of 150 mm. The appendix was returned to the abdomen and the wound closed and sealed with collodion. After 24 hours the dog was again anesthetized and the abdominal wound opened. The peritoneum was much injected in the neighborhood of the appendix and wound. The circulation in the appendix seemed good. The color of its peritoneum was about the same as that of the colon and ileum in the near neighborhood. A decided necrosis of the tissues enclosed within the ligature placed about the appendix had taken place, and fluid was escaping from the appendix at this point. This was producing an infection and the general injection of the surrounding peritoneum. The dog was now killed and the appendix removed, together with about two inches each of the colon and the ileum. The appendix was laid open and the principal effect of our experiment was found in numerous small ulcers the size of a pinhead distributed over the entire mucous membrane, no portion the size of a centimeter square being free from them. Evidently the mouths of the glands had become infected and broken down.

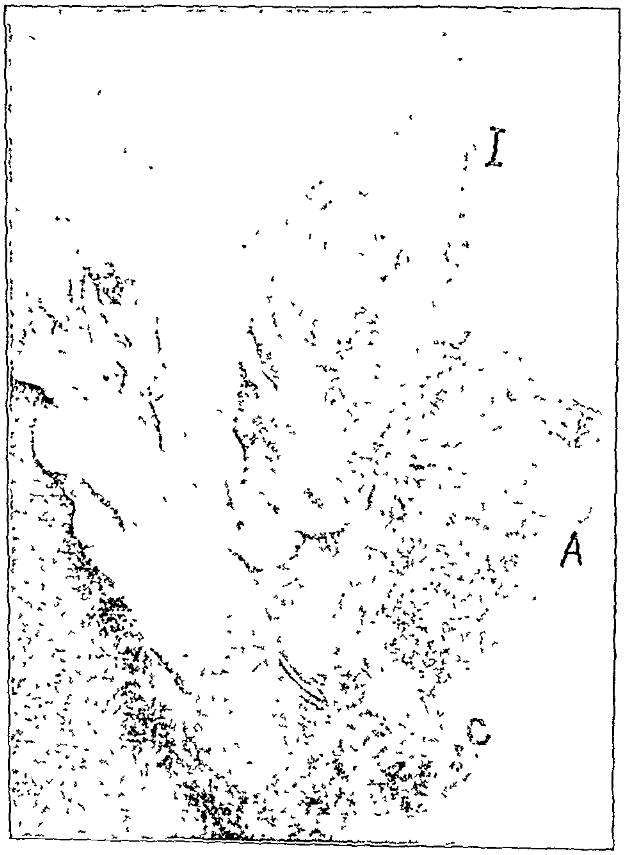

Fig 1.—Experiment 2. Specimen 2 Entire appendix inflamed and contracted I. Ilium A. Appendix. C. Colon. Photograph taken six months after preservation by Kaiserling method.

Experiment 2.—This dog was submitted to the same operation as in Experiment 1, excepting that the ligature about the appendix was passed as truly subperitoneally as possible, and 10 mm. of a broth bouillon culture of a mixture of *Bacillus coli communis* and *Streptococcus albus* was injected with a hypodermic syringe, the needle being passed alongside of the aspirating needle, used as in Experiment 1, the point of entrance being the colon and the track of the needle being closed by the ligature. This was done to insure the presence of pathogenic germs. The ligature was tied and the ends left long were passed out through the abdominal wound. The wound was now closed, two of the sutures having but a single knot so as to facilitate reopening the wound in a couple of hours. The blood tension in the femoral artery during this time was 175 mm.

[8] Nicolayson, J.: Nordiskt Medic Ark., Stockholm, 1901, vol. xxxiv, H. 4, No. 24.

Three hours later the wound was reopened, the appendiceal ligature pulled out and cut, releasing the appendix from its distention. All sutures were now securely tied and the wound sealed with collodion. Twenty-four hours after the operation the dog had a rectal temperature of 102.5. He was killed with ether and the abdomen opened. Typical appendicitis in an early stage was evident (Fig. 1).

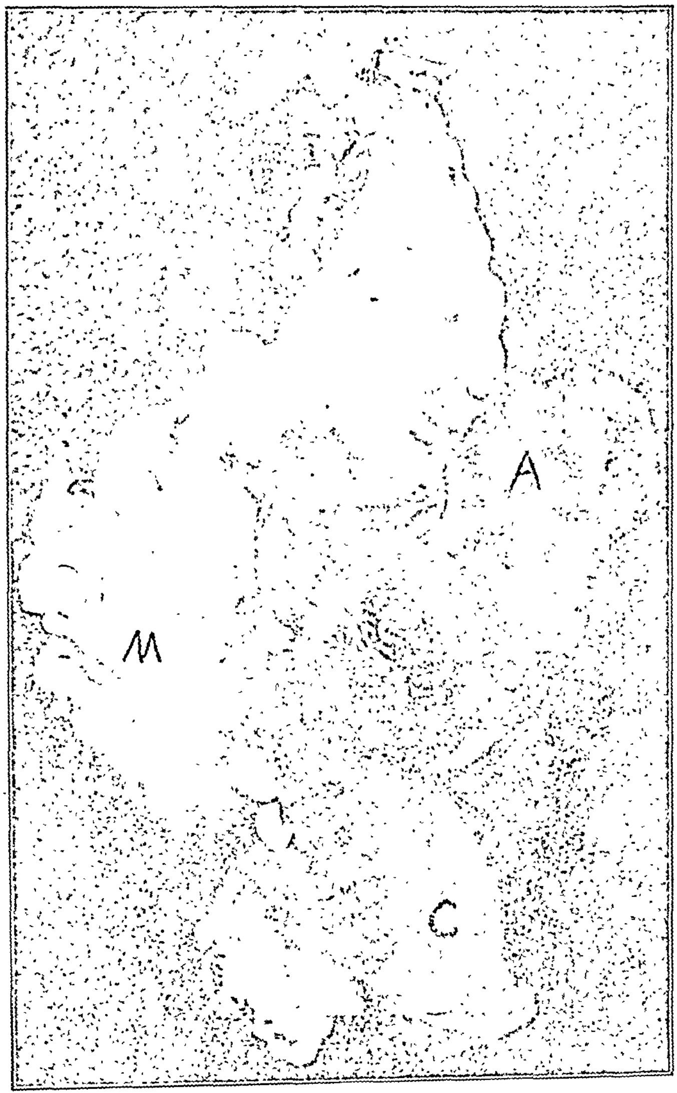

Fig. 2.—Experiment 6. Specimen 5. I. Ilium. A. Appendix. M. Mesentery. C. Colon. Photograph six months after preservation by Kaiserling method. Dark discoloration of appendix shows general inflammation.

Experiment 3.—This was the same operation as in Experiment 2, except that the distention was carried to a pressure of only 130 mm. and left for only 2½ hours. This appendix held only ¾ of an ounce. After 24 hours this dog was very lively; temperature was 99.5. There was less severe inflammation, but specimen presents just as typical a picture of appendicitis. The sphygmomanometer registered 190 on the thigh of this dog.

Experiment 4.—Simple subperitoneal ligature of the appendix without distention. No reaction in 48 hours.

Experiment 5.—Same dog as in Experiment 4. At the first operation a silk suture was simply passed subperitoneally as in previous experiments and tied tightly. The appendix at this time was 7 inches long and one inch in diameter, and considerably distended with gas. Nothing was injected into it. The day following her rectal temperature was 101 at 11 a. m. and also at 8 p. m., but she was on her feet most of the day, and did not appear ill. The morning following this, 48 hours after operation, her temperature was 99, and she was lively. The wound was reopened under ether. The appendix was collapsed and to gross appearances entirely normal. The site of the ligature was entirely covered with reparative lymph. Gas could easily be passed from the colon to the appendix and vice versa. The appendix was *again surrounded with a silk ligature* just distal to the point of the former application. The appendix was now distended to 150 mm. and left so distended, as in former experiments, for 3½ hours. After the 3½ hours had elapsed, her temperature was 97.4. The wound was again slightly opened and the appendix found still distended. The appendiceal ligature was cut and removed, and the abdominal sutures securely tied and the wound sealed with collodion. Next morning the dog's temperature was 101 and at 8 p. m. 102. At this time, 36 hours after the second operation, she was chloroformed until dead. The abdomen, opened, revealed acute appendicitis in an early stage.

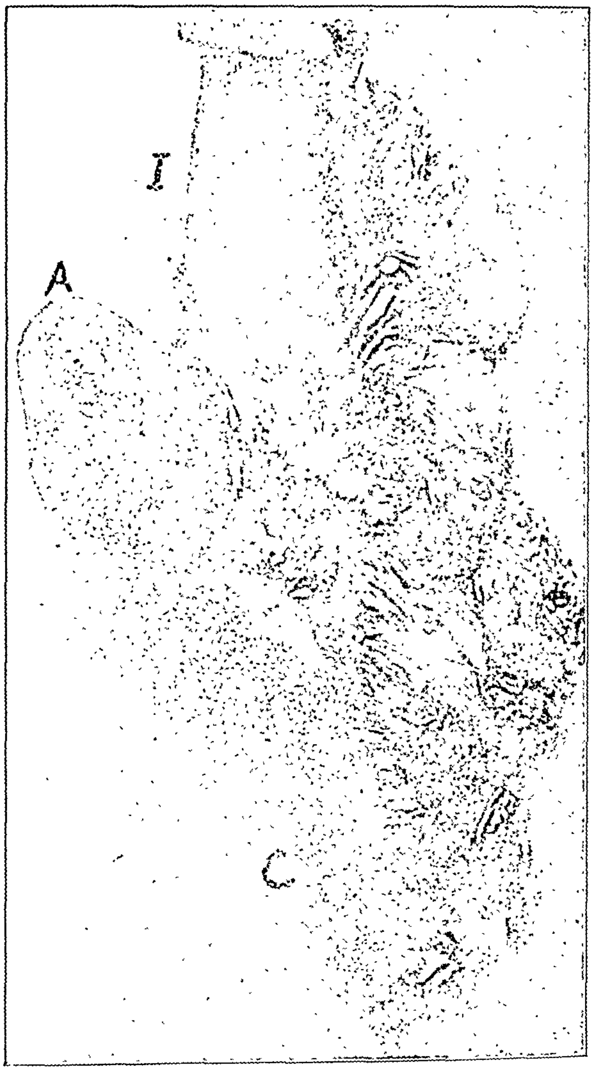

Fig. 3.—Experiment 7. Specimen 6. I. Ilium. A. Appendix. C. Colon. Experimental appendicitis. Appendix contracted by inflammation involving the entire organ beyond the ligature.

Experiment 6.—The operation was done as before, the distention pressure being 130 mm., though the ligature was not removed until after 3 hours; the pressure was probably not kept up more than one hour, judging by the actions of the dog and the collapsed condition of the appendix at the time the ligature was removed. There must have been a leak through or by the side of the ligature. After 48 hours the temperature was 102.4. Dog killed by chloroform. The appendix was found typically inflamed and contracted with numerous adhesions to the intestines and omentum (Fig. 2).

EXPERIMENT 7.—Simple distention of appendix after ligature to 130 mm. for 2½ hours. Result, appendicitis (Fig. 3).

EXPERIMENT 8.—Injection of 10 mm. of culture *Bacillus coli* and *Staphylococcus albus* without distention. No reaction.

EXPERIMENT 9.—Appendix ligated and distended to 100 mm. and left 48 hours. Result, severe appendicitis.

EXPERIMENT 10.—Distention to 75 mm. Ligature. After 8 hours the wound was reopened and the appendix found collapsed, congested and inflamed. The ligature was not molested, but the appendix returned to the abdomen and the wound closed. Twenty-four hours after the operation the temperature was 99.5. The dog was killed with chloroform, and abdomen opened. The appendix was imbedded in a mass of adhesions by an inflammation of which it was itself the center. Its serous membrane was red, congested and inflamed. It was contracted down on a hard fecal mass plainly felt through its walls like a fecal concretion. Laying it open, it was evident that the ligature had cut into the tissues of the wall of the appendix sufficiently to allow the opening into it to become patulous, though not cutting quite through the mucous membrane. The fecal mass previously felt now showed itself a hard dry lump composed of the compressed feces present in the appendix on the previous day when the ligature was placed (Fig. 4). It illustrates well the origin of the fecal concretion as I have outlined it elsewhere. The contracting appendix had driven off all the fluid into the colon. We need only to imagine more time—days, weeks, months, years—and the decomposition of the organic matter in this mass and the addition of more material from time to time would do the work of forming a concretion.

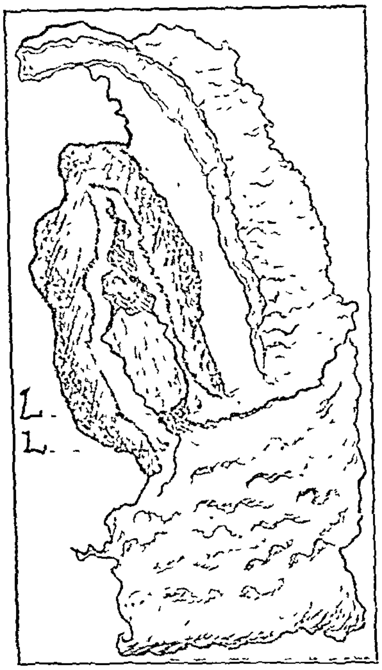

Fig. 4.—Experiment 10 Specimen 8. Ilium and colon laid open. Appendix inflamed and contracted, showing fecal ball held by constriction at site of ligature. Divided ends of ligature indicated at L L.

These ten experiments may be divided into the following five groups:

Group 1. Attempted permanent subperitoneal ligation of the appendix with distention to various degrees of pressure. Experiments 1, 9 and 10.

Group 2. Temporary subperitoneal ligation of the appendix with distention to various degrees of pressure. Experiments 5, 6 and 7.

Group 3. Temporary subperitoneal ligation with distention and injection of cultures of pathogenic germs. Experiments 2 and 3.

Group 4. Simple subperitoneal ligation of appendix. Experiment 4.

Group 5. Simple injection of cultures of pathogenic germs into the lumen of the appendix. Experiment 8.

Group 1 was done with the object of testing the possibility of inducing appendicitis in dogs by distending the appendix and producing a pressure within it equal to or just exceeding that of the arterial supply of the appendix. The normal blood pressure in the large arteries in dogs ranges from 90 to 160 mm., being about equal to that in the human being. Aiming as near these figures as possible, we applied 150 mm. pressure to the first case, 100 in Experiment 9, and 75 in Experiment 10. The attempt was made in this group to retain these pressures permanently. In this we failed in each case, because after a few hours the ligature had cut through enough tissue to allow a leak to occur and thus to relieve the tension. A permanent occlusion ought to produce a perforating or gangrenous appendicitis, but on account of this cutting of the ligature the manner in which this process in the human appendix can be imitated is very difficult. However, this demonstration is not very important, since if our results after temporary occlusion can be accepted as demonstrating the cause of mild appendicitis the frequency of permanent occlusion in the human appendix is sufficient demonstration as to the cause of the perforative and gangrenous cases.

In Group 2 pressures were induced in Experiment 5 of 150 mm.; Experiment 6, 130 mm.; Experiment 7, 130 mm., and the ligature removed in two and one-half to three hours. The resulting inflammation in all these cases, as well as in those of Group 1, demonstrated that infection will take place promptly from the pathogenic germs present, even in the healthy appendix of a dog, if that appendix is subjected to an intra-appendicular hydraulic pressure equal to or slightly exceeding the blood pressure in the arteries, even if this pressure is maintained for only a short time. The weight of these demonstrations is enhanced by the striking identity of the picture of these results and those of ordinary acute appendicitis in a correspondingly early stage, as we see it daily in the operating room.

In Group 3, cultures were introduced to make certain that the appendix contained pathogenic germs, for manifestly that is the all-important factor in any infection. The result was a slightly more severe type of inflammation.

In Group 4, Experiment 4 was done in the hope of obtaining a permanent occlusion and subsequent filling up of the appendix from the retained secretions. The uselessness of this attempt is now very evident on account of the cutting of any ligature placed for this purpose.

In Group 5, Experiment 8 was done as a control of 2 and 3 to show that simple injection of virulent germs into the appendix does not produce infection. This is in line with some of the experiments of Beausenat and of Roger and Josue,[9] who report the same failure of results.

Let us compare this view of the cause of appendicitis with those most commonly accepted. Anything like a complete review of the literature on the subject is out of the question here. The articles written about appendicitis number up into the thousands. Dr. J. B. Murphy[10] summarizes the etiology as follows:

---

[9] Roger and Josue: Rev. de Med, Paris, 1896, vol. xvi.

[10] Murphy, J. B.: Practical Medicine Series, November, 1902.

> We are agreed that the etiologic factors of appendicitis are:
>
> 1. A local irritation caused by a foreign body, as a fecal concretion, a catarrhal congestion of the appendix due to the conditions which produce similar changes in the neighboring bowels, stercostasis in the appendix, traumatism, etc.
> 2. The inoculation on this abraded mucosa of pathologic flora as the staphylococcus, streptococcus, pneumococcus or colon bacillus.
>
> The consequences of this infection are the many pathologic conditions which are present in acute inflammatory process.

This fairly represents the consensus of opinion on the matter as I read the voluminous literature on the subject, but that it is not a fully satisfactory explanation is shown by the multiplicity and variety of other explanations offered. A list of thirty-nine different explanations was compiled during our search of the literature.

This theory seems to overlook the difference in character of the infection here and in any other part of the alimentary canal.

To produce a necrosis, an infection must be so severe as to produce cell necrosis by the character or virulence of the germ, or it must continue long enough to accumulate inflammatory products which by pressure on the blood vessels produce the necrosis (Senn). Neither of these conditions prevails in appendicitis.

The striking tendency to necrosis and gangrene early in appendicitis point to a mechanical interference with the blood supply. Nearly all pathologists speak of the changes in the blood vessels. I need mention only Fowler, Deaver and Ochsner.

To establish the universality of the two essential factors, the constriction and the occluding mass, may be difficult from the data now on record, but the constant reference to them by writers and the prominence they have maintained in the discussions of the cause and pathology of the disease, speak for their frequent, if not for their constant, presence.

I have never seen an appendix which presented evidence of inflammation, past or present, which did not present a constriction in some part of its lumen. A very slight narrowing may be sufficient to moderately distend the appendix for a short time. A hard fecal mass may be a long time passing a bend or kink in the lumen. These irregularities increase as bowel contents enter and are forced out. The recurring distention tends to produce pouching beyond anything acting as a constriction, a kink or bend, a short mesentery, etc. This is explained in detail by R. Abbe.

The frequency of the obstructing body has been the subject of much more study. Aside from soft or firm fecal matter, which must be conceded to be always possibly present, the prevalence of foreign bodies and fecal concretions is common knowledge.

Mitchell[11] collected 1,400 cases from various sources in the last ten years and found about 7 per cent. of true foreign bodies; while in 700 of these cases, in which a definite statement was made as to the nature of the foreign body, there were 45 per cent. of fecal concretions. Fitz, in 1886, collected 152 cases of perforative appendicitis and found 12 per cent. foreign bodies, with 47 fecal concretions. Talamon, 760 cases, 450 foreign bodies or concretions, nearly two-thirds of the cases. Hartley adds: "Is it unreasonable to assume that the other third had escaped into the colon after temporarily obstructing the lumen?"

However, a concretion is not essential. Any fecal mass may become sufficiently firm to be packed into a constriction and temporarily occlude the lumen. Such an obstruction will the more easily give way because it is pliable. Beside, there are putrefactive changes always going on in it, favoring the giving way of the obstruction once the valve is closed.

The determination of the source of the fluid with which the appendix is distended is an interesting and important problem. Much of it and sometimes all of it must come from the effusion into the canal from the engorged blood vessels of the mucosa, together with the secretions from the glands.

Hemmeter says: "If the obstruction is complete, abundant secretions accumulate and are readily decomposed in the presence of numerous putrefactive bacteria. The walls of the appendix are excessively distended and the mucous membrane is strongly irritated, both mechanically and chemically."

Blood is pumped into the appendix under a pressure of 90 to 170 mm. The capillaries and veins are compressed against the fibromuscular walls, and in whole or in part occluded. The blood stream is slower than normal and effusion must take place. With every drop of effusion the intra-appendicular pressure rises and the occlusion of the blood vessels becomes more complete. This process continues until the pressure in the arteries and in the canal of the appendix becomes equalized. Blood has been pumped into the appendix, but was prevented from escaping through its ordinary channels, and must be retained there. Formation of gas in the appendix may add materially to the degree and rapidity of the distention.

The sudden onset of many acute cases, such cases so often referred to as due to trauma, an acute indigestion, violent exercise or constipation, seems to indicate that at times at least the initial distention is produced by a sudden increase of pressure in the colon, forcing an unusual amount of fluid into the appendix, which is held there by the fecal mass or concretion suddenly rebounding, closing the ball valve. The ease and perfection with which this maneuver may be carried out with the appendix shown in Figures 5 and 6, is confirmatory of this idea. Once the occlusion established, the previous process of effusion continues to increase the pressure.

The following cases illustrate this sequence—constriction, obstruction, distention, pressure on blood vessels, infection, and gangrene and perforation:

Case 1.—E. R., male, aged 22. Taken suddenly on the evening of March 24, 1903. Kept in the house the 25th and went to bed that afternoon. Pain quieted down that evening and was very moderate all the next day. That day he attended a picnic, and, being an athlete, he did considerable jumping. Came to me that midnight with severe pain. The morning of March 27 pain very slight, but decided tenderness on pressure. Operation 10 a. m., 60 hours after onset, 20 hours after last exacerbation. Appendix found distended to an extreme degree, "as full as it would hold." "Feared it would pop open before it could be removed." Closely examining it after removal one easily caught the greenish tinge of approaching gangrene of the entire organ. A concretion the size of an orange pit was easily palpated, blocking a tight constriction, at the proximal end. Pushing this back released the fluid and the tension was immediately relieved. Infection had not extended beyond the walls of the appendix. The patient made an uneventful recovery.

I used this appendix in my first experiments on this subject, as shown in the illustrations (Figs. 5 and 6). It was possible, with the aid of the bulb syringe, to distend it fully and, the valve closing, this tension was maintained by the recoil of the fluid on the concretion, forcing it into the constriction, the ball valve causing appendicitis.

---

[11] Mitchell, James F., The Johns Hopkins Hospital Bulletin, Baltimore, 1899, vol. x.

To my mind, the life history of that appendix was as follows: At birth the appendix was slightly club-shaped. The lumen was a trifle narrower at the juncture with the cecum than at some point distal to it. For years fecal particles accidentally passing into it would be easily expelled, as the constriction was so slight as to offer no real impediment to its exit. In time a little accumulation of fecal matter occurred and slightly distended the walls until it took some effort on the part of the appendix to expel it. Repeated occurrences of this kind developed an increasing distention of the appendix and a relative narrowing of its lumen at its already narrowest point. In time the passage of such a fecal bolus irritated the mucous membrane at the narrowed point—perhaps by stretching and causing microscopic injury. Slight local infection and resulting inflammation contracted the lumen at this point and produced a more decided constriction. This constriction following mild inflammation of the appendicular mucosa, was studied and described by R. Abbe.

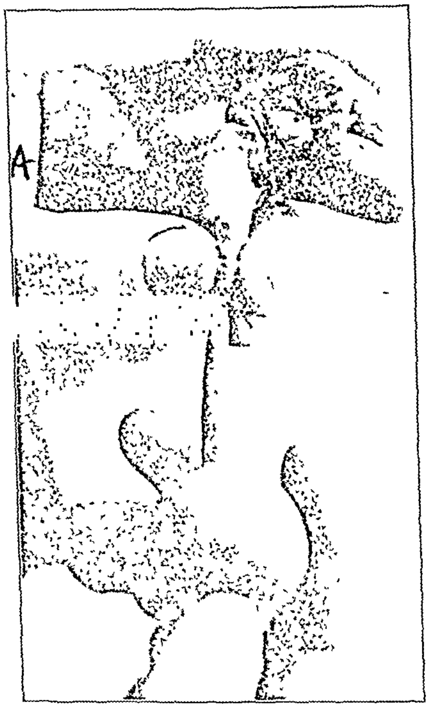

Fig. 5.—The "ball valve" action of a concretion causing appendicitis. The appendix ready to be filled from the bulb.

A repetition of this process continued until the constriction presented a decided obstacle to the exit of fecal contents. The fluid portion of the bolus was, however, constantly expelled or absorbed. Inorganic matter remained as the principal constituent of the mass, which constantly grew by accretion, and a fecal "concretion" resulted. It may have been so much reduced in size during a period of time when little or no fresh mass was forced into the appendix that it easily escaped into the colon without producing a symptom. More than likely, however, at some time it caused enough obstruction to its exit to produce an occlusion. Distention with fluid followed, partly perhaps by some sudden increase of intracolonic pressure forcing it into the appendix—the concretion or fecal mass dropping into the constriction and retaining the fluid there as would a ball valve. At any rate, the secretions from the mucosa being prevented from leaving the closed cavity accumulated, whether the initial distention came from the colon or not. The increasing pressure, the appendicular contractions, the distensibility of the constriction, and, if still pliable, the molding of the mass, one or all of these factors caused the obstructing body to pass the constriction in a short time. Meanwhile, the capillary and venous circulation had been compressed, and more or less bacteria had gained entrance into the tissues, causing more or less infection and inflammation. Some bacteria entered through follicles unduly opened by the distention and others through microscopic traumatisms, but the important condition which allowed infection to occur was that the tissues were temporarily deprived of their life fluid, the blood, without which no tissue can long withstand the attack of its germ foes. The result of this temporary obstruction in the appendix was a mild attack of appendicitis,

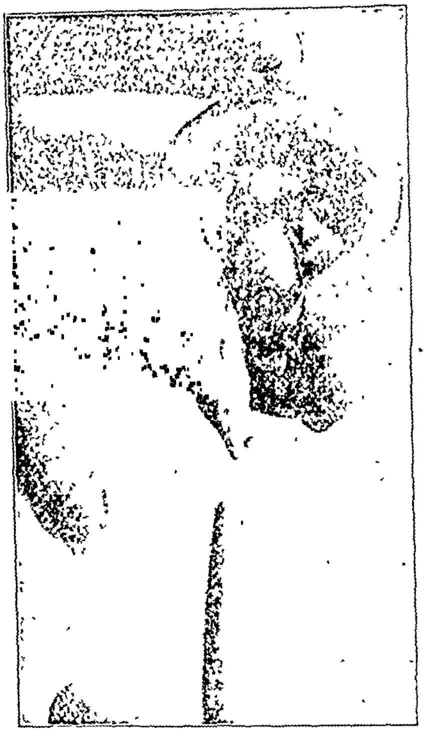

Fig. 6.—Same as Figure 5, filled and with the "ball valve" closed, retaining the fluid under pressure.

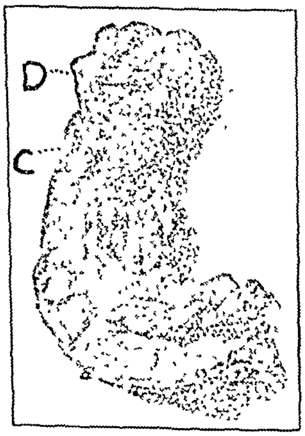

Fig. 7.—Specimen from Case 2. Distal extremity dilated (D) beyond constriction (C). *Concretion occupied dilated portion.*

producing so little pain and discomfort that it passed unnoticed or as a colic or as a bilious attack. Patient remembers long nights with "stomachache" when a boy, even when a student in the high school. Some of these were probably mild attacks of appendicitis and may have been repeated a number of times.

Coming now to the time of his final attack, the constriction and the concretion were there as demonstrated by the specimen. The history of their production I have attempted to sketch. On Tuesday evening the "ball valve" was closed, accidentally (?). It may have been from increased intracolonic pressure or by his position at night the concretion may have dropped by gravity into the constriction and the secretions accumulating behind it held it there firmly. The valve once closed and the fluid accumulating behind it, more and more pressure on the blood vessels of the mucosa and submucosa followed, and some infection became established. During Wednesday the valve must have been opened by the concretion falling back into the appendix, or by some misfit it was allowed to leak a trifle at a certain pressure for the patient had comparatively little pain that afternoon and night. The next morning (Thursday) he felt well enough to attend a picnic with some of his pupils. Being of an athletic turn, he engaged in various feats of rowing, running and jumping, and even cleared a table at one bound. His pain had been slight during the day, though always present, but after this last feat his pain increased decidedly. What better explanation can be offered than that with this extra muscular effort there was unusual compression of the colon, fluid was forced into the appendix under great pressure and the valve again closed, this time for good? The pressure on the blood vessels and effusion began at once and continued until the pressure in the lumen of the appendix equaled that in the arteries, as already described. Pain increased until midnight, by which time the obstruction to the arterial blood current had become complete and gangrene began. From this time on the pain subsided, as the nerves producing it gradually succumbed to the advancing gangrene.

The intra-appendicular pressure, once established, must of necessity be maintained until something gives way. A greater distention of the walls will only allow a little more fluid to enter from the arteries. Had the constriction been less firm or the concretion smaller or more easily molded, it might have been forced open, as it had perhaps done before or as it undoubtedly often does even at such a late hour that complete gangrene of the appendix is already established, and at operation we find the gangrene, but the concretion has passed out of sight into the colon, the obstruction is gone, and we wonder at the wonderfully acute infection which in twelve to thirty-six hours produces gangrene of the entire appendix. Ochsner reports such cases as I have already mentioned.

Case 2.—M. V. Z., aged 15. Since February, 1899, she had three or four mild attacks of typical appendicitis. Each time the pain came on suddenly and left suddenly within a few minutes or hours, leaving only a tenderness in the region of the appendix for one to four days. The last attack occurred about Jan. 1, 1902. The pain came on suddenly, was severe, but subsided after about 45 minutes. After that there was decided tenderness to pressure and slight tenderness when turning about, but no further decided pain. The temperature reached 100 within the first few hours, but did not exceed the normal point after that. In three days she was perfectly well. Three weeks later, January 25, the appendix was removed, and is shown in Figure 1. The constriction was found about one inch from the distal extremity. The distended cavity beyond was entirely empty, as shown in the cut. That cavity must have contained a concretion or fecal mass. The cavity became suddenly distended, the constriction obstructed, and the pressure on blood vessels and nerves decided. Fortunately, the obstruction was forced out through the constriction before serious infection or gangrene had time to develop. Some infection had taken place, however, as the clinical history and the pathology of the specimen are evidence of a typical so-called catarrhal appendicitis.

Case 3.—Miss C. F. B., aged 24. I saw the patient at 4 p. m. Sept. 16, 1903. During the preceding night she had been taken with pain, which had gradually increased in severity. Operation was advised, and was begun at 10 p. m. The appendix was found fully distended and omentum slightly adherent, especially at the distal end. Removing the adhesions revealed two dark gangrenous spots. The degree of distention in this case was an interesting study. I know of no way to measure or record it. But having just recently completed my experiments on dogs I had some idea of pressure measured by the manometer, and I do not hesitate to say that it exceeded 100 mm. and, perhaps, 150, at least enough to seriously interfere with the blood supply. The concretion and stricture which caused the obstruction were situated about midway between the point and the proximal end of the appendix.

These cases are just such as are constantly seen in the operating room, and are cited simply to show how their history, especially of pain, fits into this view of the pathology. Had Cases 1 and 3 been left until perforation had taken place, all evidence of the actual cause of the appendicitis would have disappeared and the blood vessels would have given no account of the force which had compressed them. Thrombi would have been present in their lumen, but this simple mechanical explanation of their production would have passed out of evidence.

Appendicitis must be looked on as at first a true strangulation—pressure on the blood vessels. This theory explains the suddenness of the onset, especially if we allow that the first distention and closure of the valve is produced by increased colonic pressure. The sudden cessation of acute pain so often observed is explained by the giving way of the obstruction and the gradual cessation of pain by the advent of gangrene.

The severity of the pain (if only we could measure it) and the length of time it continues should be a valuable indication of the severity of the inflammation likely to follow, especially if it comes suddenly and leaves suddenly. If the initial pain of appendicitis is due to a simple infection, why does the pain so frequently subside after a few minutes or hours while the infection continues to extend? In this connection a sharp distinction must be made between pain and tenderness. Pain before the inflammation has extended to the peritoneum (usually eighteen to forty-eight hours) means distention still present, especially if accompanied by colic, which means attempts at extrusion and peristalsis extending to the intestines. Tenderness before the peritoneum is involved without decided pain (a condition so common after a few hours, three or four, to twenty-four or forty-eight) is evidence of congestion or inflammation confined to the appendix. The recurrence of pain after this lull is almost invariably rupture and extension to the peritoneum. The careful study of the history of pain and tenderness in any case furnishes the most important evidence we have of the exact conditions present.

If appendicitis is at first strangulation, the importance of early operation, before the inflammation reaches the peritoneum, can not be too strongly emphasized. In some cases the evidence of the early giving way of the obstruction may be sufficiently positive to admit of a diagnosis to that effect and an assurance of a mild attack that will not require an operation until "the interim." But this decision must rest on the most positive evidence after a painstaking study of the history and present condition of the patient. With such positive evidence furnished by Case 2, I believe that plan justifiable. But when in doubt, operate before perforation has taken place.

CONCLUSIONS.

1. Simple infection does not account for the suddenness of the attack nor early severity of the pathologic changes in acute appendicitis.
2. The evident interference with the blood supply is best accounted for by an increased intra-appendicular pressure.
3. Simply injecting bacteria into the appendix will not produce appendicitis unless used in abnormal amounts and virulence.
4. Subperitoneal ligation of the appendix with a simple ligature without distention can not be made sufficiently permanent to produce a general infection of the appendix, typical of appendicitis in the human being.
5. Experiments in dogs show that hydraulic pressure equal to the arterial tension maintained within the lumen of the appendix for a short time is promptly followed by typical appendicitis.
6. The blood supply in an extremity may be cut off with impunity for hours; but in the appendix the ever-present bacteria at once begin an infection, their entrance into the tissues being facilitated by the opening of normal and traumatic avenues by the very distention which cuts off the circulation.
7. The importance of making a complete diagnosis and prognosis during the first twelve hours of the attack is emphasized.
8. This study suggests the possibility of infections or other lesions being produced in other hollow viscera, especially in the gall bladder, the stomach and intestines by temporary overdistention.

Clinical Reports.

LEUKEMIA.

REPORT OF A CASE SYMPTOMATICALLY CURED BY THE X-RAY.

EVERETT J. BROWN, M.D.
DECATUR, ILLINOIS.

Introduction.—A case of splenomedullary leukemia successfully treated by the use of the Roentgen ray is reported by Senn.[1] In looking up the literature at my disposal, which includes the *Index Medicus*, I fail to find any further reports of cases thus treated.

At the time of the appearance of Senn's report, the patient, whose history I give below, had been under *x*-ray treatment for seven weeks.

From the time of the first recognition of this disease a fatal termination has always been expected, yet it is known that occasionally recovery occurs, or there is an apparent arrest, either spontaneously, or after the use of arsenic; hence in recording the effect of any treatment of leukemia the word "cure" must be used with caution. Although an examination of my patient to-day would show an entire absence of every symptom of the disease, both by physical and blood examination, where seven months ago a most pronounced case existed, yet only time will show the permanency of the result.

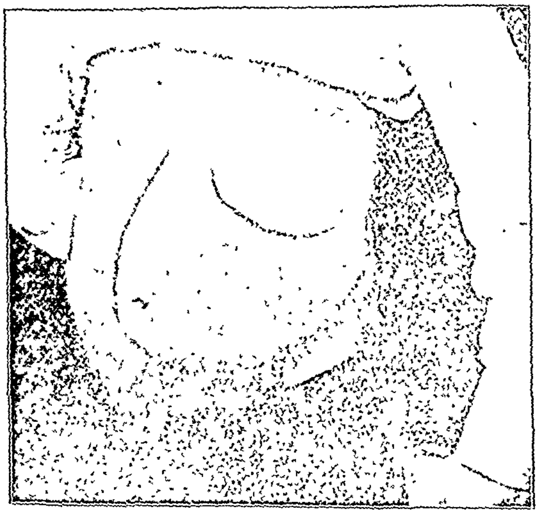
I submit this as a preliminary report, and will later collect other cases so treated, and will give a more detailed history of this one, with charts and plates showing the blood findings.

Patient.—W. E., male, American, aged 30, a cigar maker, unmarried; was first examined July 1, 1903. His family history is negative, except that one sister has had tuberculosis.

History.—The patient has lived in Decatur all his life; his habits have been good, he does not use alcohol, but he is a moderate smoker. He has had the usual diseases of childhood, with good recovery in all. No history of malaria or syphilis.

Present Trouble.—The patient came to the office complaining of weakness, pain in the back and a feeling of weight and distress in the left side. Two years ago he had a fall, alighting on lower ribs of left side, which compelled him to stop work for two days. He has had a slight cough for some time. For six months he has been troubled with palpitation, dyspnea and slight headaches. Lately he has noticed that his shoes fit tighter at night. He becomes very weak on exertion.

Examination.—The patient is moderately well nourished, but has a somewhat cachectic appearance. His present weight is 169 pounds, which is his average summer weight; his expression is depressed; mind clear; frame medium sized; musculature soft; panniculus thin. He is slightly anemic. The visible mucous membranes are of fair color; tongue is moist. There is slight edema of ankles and legs. The lymphatic glands are not enlarged, but the inguinal glands are easily palpated. The thorax is of good size and symmetrical; expansion fair. On percussion, one finds good resonance, the lower lung boundaries normal and descending well; heart sounds are normal; the liver dullness extends to the edge of the ribs, and its thin edge is easily felt. Splenic dullness begins on the seventh rib in the mid-axillary line and extends two fingers' breadth below the navel in the left mammary line. To the right it extends one finger's breadth beyond the median line. On palpation the spleen is a hard, smooth, thick mass. No notch can be felt. The radial pulse is easily compressed, is moderately full and regular, with a rate of about 90. Temperature is 99.



Splenomyelogenous leukemia. Photograph showing size of spleen before treatment and after four months' treatment.

Examination of Fluids.—The urine gives a slight precipitate with heat and acid, and a few hyaline casts are found in the sediment. The blood examination, made by my associate, Dr. C. M. Jack, is as follows: Red blood corpuscles, 2,600,000; leucocytes, 800,000; hemoglobin, 65 per cent.; specific gravity, 1,050. On staining with Ehrlich's triple and Janner's stains, the reds show a slight paleness, slight poikilocytosis and many nucleated forms. The differential count of the leucocytes gives: Polymorphonuclear, 40 per cent.; myelocytes, 40 per cent.; eosinophiles, 8 per cent.; large mononuclear with basophilic granules, 8 per cent.; degenerates, 4 per cent.

---

[1] New York Medical Record, Aug. 22, 1903

Clinical Diagnosis.—Splenomyelogenous leukemia.

Treatment.—The patient was informed of his condition and advised to stop work. I gave arsenic and iron internally and *x*-ray treatments to the splenic region twice a week.

Course.—After one month the patient seems improved; feels stronger, and his appetite is better. On examination the spleen is apparently smaller, the right edge extending only to the sternum and the lower edge on a line with the navel. The ankles are still swollen, but the blood shows a marked decrease in the number of leucocytes with a slight increase in the red blood corpuscles and in the amount of hemoglobin. Blood smears show an apparent increase in the transitional forms with decrease of myelocytes. The normoblasts are markedly increased. Differential counting is unsatisfactory owing to the large number of forms lying on the borderline between the myelocytes and transitional forms. The urine still contains a trace of albumin.

September 1: The patient has returned to work. His general condition is improved; appetite good, with a gain in weight. The spleen has decreased in size and a notch is felt for the first time. Edema of ankles is less. Blood: leucocytes decreased to 58,000, with an increase in the red blood corpuscles to over 3,000,000.

Encouraged by the results of treatment, which had varied very little in the last two months, and by Senn's article which appeared at this time, it was decided to discontinue the iron and arsenic and to increase the frequency and distribution of the *x*-ray exposures. These treatments were now given daily to the splenic region, the ends of the long bones, and to the sternum. In place of the iron and arsenic, one grain capsules of quinin, three times a day, were given as a placebo.

October 4: The patient has not missed a day's work in the last month. The blood shows an increase in the number of leucocytes; the number of red blood corpuscles and the amount of hemoglobin, however, still show an increase. The spleen can be pushed to the edge of the ribs. An *x*-ray dermatitis of the splenic region has appeared once or twice, the outer layers of the skin desquamating, but by discontinuing treatment for a few days and using a dusting powder, no bad results have followed. The skin over the exposed surfaces was rough at first, but after exfoliation has become smooth again. The hair and pigment have disappeared from the parts exposed.

November 9: Blood: leucocytes, 129,000; red blood corpuscles, 4,124,000; hemoglobin, 85 per cent. Very little variation in size and shape of the red blood corpuscles and no nucleated forms were found. Myelocytes, 25 per cent.; polymorphonuclear, 60 per cent.; eosinophiles, 5 per cent.; small lymphocytes, 1 per cent.; degenerates, 3 per cent.

December 6: Leucocytes, 44,360; red blood corpuscles, 4,360,000; hemoglobin, 85-90 per cent.; myelocytes, 20 per cent.; polymorphonuclear, 74 per cent.; eosinophiles, 1 per cent.; small lymphocytes, 2 per cent.; degenerates, 3 per cent.

January 9, 1904: Leucocytes, 17,825; hemoglobin, 90 per cent.; red count not taken. Myelocytes, 8 per cent.; polymorphonuclear, 88 per cent.; basophiles, 2 per cent.; small lymphocytes, 4 per cent.; degenerates, 1 per cent.

February 13: Leucocytes, 10,980; red blood corpuscles, 4,600,000; hemoglobin, 90 per cent.; polymorphonuclear, 86 per cent.; small lymphocytes, 8 per cent.; basophiles, 1 per cent.; transitional forms, 2 per cent; degenerates, 3 per cent. The albumin has entirely disappeared from the urine. The patient's weight to-day is 182 pounds, more than he has ever weighed before. Spleen can only be felt on deep palpation and on deep inspiration. Treatments are now reduced to every other day, the patient taking long walks on the intervening days.

February 20: Leucocytes, 7,894; red blood corpuscles, 4,690,000; hemoglobin, 95 per cent.

The accompanying table shows the remarkable reduction of leucocytes. It shows the first reduction when patient was taking both the arsenic and *x*-ray treatment, then the increase in the white cells when the arsenic was discontinued and the subsequent decrease to normal after *x*-ray treatments were given alone.

	LEUCOCYTES.	TREATMENT.
July 1	800,000	Arsenic and *x*-ray.
Aug. 1	160,000	
Sept. 1	58,000	X-ray alone. Arsenic discontinued.
Oct. 4	106,000	X-ray alone, daily treatments.
Nov. 9	129,000	
Dec. 6	44,000	
Jan. 9	17,825	
Feb. 13	10,980	
Feb. 20	7,894	

A CASE OF PSEUDOLEUKEMIA SUCCESSFULLY TREATED WITH *X* RAYS.

OSCAR W. STEINWAND, M.D.
Member American Association for the Advancement of Science.
SELMA, CAL.

Patient.—Miss L. N., aged 15, school girl. Family history: mother died from heart disease two years ago; father well; 3 brothers, 2 well, 1 has chronic stomach trouble; 3 sisters, all well. No tubercular or syphilitic history.

History.—About five or six years ago she noticed that the glands on the left side of the neck became enlarged, but not painful. During the succeeding three years they increased slowly but gradually, and there were occasional sharp pains on left side of abdomen (site of spleen). These were of a lancinating character and of momentary duration. Certain nervous symptoms made their appearance: inability to concentrate her thoughts on her studies, sleeplessness and pains in her legs, the latter causing some unsteadiness of gait. Her disposition likewise suffered, changing from a bright cheerful tone to one, at times, bordering on melancholy. Two years ago the glands along both borders of the sternocleido muscle began to coalesce and to make more rapid progress in size. The supraclavicular glands also became prominent, and in due time also the axillary glands were involved.

The patient came to me for treatment April 1, 1903. She presented all the symptoms above enumerated, with rapidly increasing nervous phenomena and steady loss of weight. All the treatment she had received had had absolutely no effect toward checking the disease. There had not been any definite diagnosis. Some had suggested entire removal of the diseased glands, but her parents would not consent.

Examination.—There were large glandular masses on the left side of the neck, anterior and posterior to the sternocleidomastoid muscles, the larger ones about the size of a hen's egg. They were movable under the skin, but bound down more or less to the deeper structures. The supraclavicular and epitrochlear glands were likewise affected.

The spleen was somewhat enlarged and tender to pressure. Temperature was 100 to 101 degrees. The hemoglobin index was 70 per cent. The differential leucocyte count was negative. I failed to make a blood count. The pulse was 115 to 120. At no time did I detect the temperature lower than 100 degrees or the pulse rate less than 102.

Treatment.—Under the use of Fowler's solution for three weeks the patient rapidly grew worse. April 20 I advised the use of the *x* rays, and gave the first exposure, eight inches from the surface of the neck. The neck measured 13½ inches over the most prominent portion. I made one exposure each day, of a duration of fifteen to twenty minutes. After the exposure on the second day, the patient complained of feeling much worse. The temperature now registered 104.5, the highest it had been at any time. The following morning it was again 102, and remained so until one-half hour after the exposure in the afternoon, when it reached the same mark as on the preceding day

Thinking there might be some latent malaria, I examined the blood, with negative results, and administered 12 grains of quinin per day for four days, but without any effect whatever. After the third exposure, splenic tenderness was greatly increased, so that gentle percussion caused considerable pain. The patient now felt so miserable (to use her own expression) that she kept her bed all day except at the treatment hour.

April 24 her neck measured 12½ inches and had visibly decreased in size. Two days later it measured 12 inches. The temperature was 103, the pulse 115.

April 27 I commenced giving Fowler's solution as a general tonic. On April 29 I stopped the quinin. The patient was feeling somewhat better and more cheerful. On April 30 the neck measured 11¾ inches. The supraclavicular glands were much shrunken and becoming hard, nodular and more freely movable under the skin. Temperature was 100, pulse 100.

May 1 I stopped *x*-ray treatment, as there was some evidence of burning. On May 5, temperature was 98.4; pulse 100, this being the first time I found temperature normal in three months' observation. The *x*-ray burn was now very evident, being of oval shape, about 2 inches wide by 4 inches long, with desquamating surface. There was some burning and itching, with alopecia on that side of the head. She felt much better and had gained four pounds in weight. The glands felt much harder and more nodular, and were loosening from the deeper structures. The pains in the legs had disappeared, but the knees still felt very weak when she stood any length of time. All nervous symptoms, tremor, etc., have disappeared.

May 12 the *x*-ray dermatitis was fully developed, and the skin was sloughing in places. The area of alopecia was somewhat increased. She had a keener appetite. The weakness in the knees had disappeared and she gained 2 more pounds in weight. The bowels had become regular. The temperature was normal and the tongue clear.

May 28 the *x*-ray burn showed signs of healthy granulations, and on June 3 skin grafts from the thigh were applied to the denuded area under medullary narcosis, which proved to be a very efficient and convenient anesthetic.

June 6 all grafts had united and the inflammatory condition subsided.

July 24 the glands were still receding, and the neck measured 11 inches. The contour fairly matched that of the opposite side. She stated that she felt in the best of health, and her appearance fully bore out her assertion.

Apparatus and Technic.—The current I obtained from a 16-plate static machine driven by hand. I used a Gundlach tube, taking a 4-inch spark gap. The target of the tube was placed 18 inches from the patient, with one treatment of twenty minutes' duration each day for the time stated.

Comments.—As treatment progressed, the spleen increased in size. This phenomena was noted by Senn in The Journal, but I have not seen any mention of the distinct rise in temperature after each treatment, encountered in this case. The only explanation that I can offer is that there must have been certain toxic products, liberated through the influence of the *x* rays, which were at once taken up by the circulation, causing also the acute exacerbations of ill feeling following each exposure. This condition of elevated temperature and ill feeling lasted from ten to fourteen hours, and was so severe at times that we both thought of abandoning treatment had it not been for the steady reduction of the size of the glands.

Present Condition.—At the present time, Feb. 22, 1904, all the formerly enlarged glands have receded to their natural size, but still retain their hard fibrous condition. The patient is and continues in the best of health, no trace of the disease remaining.

I intend to keep her under observation for some time, as it is too early to report a permanent cure. The result obtained has been very satisfactory, especially since the outcome of this disease, under the use of other therapeutic agents, has been almost invariably fatal.

New Appliances.

A SIMPLE CLUBFOOT RETENTION SPLINT.

JOHN C. SCHAPPS, M.D.
Late Orthopedic Surgeon to the St. Mary's and the King's County Hospitals, New York.
BUTTE, MONT.

The treatment of a clubfoot should be commenced immediately after birth, when it can be cured by pressure. The lateral and then the anteroposterior element should be successively dealt with. In older cases where an operation of some sort is necessary, the complete overcorrection is best made at once. To partially correct such a case by operation, trusting to apparatus or body weight to complete the rectification, is to invite disappointment. For the clubfoot is not simply a misshapen foot. It is a clubfoot by reason of a peculiar distorting force which is actively at work in it. This force, if not overcome, increases rapidly. It is stimulated by unbalanced muscular movements, by weight bearing and frequently by the very measures which are employed for the cure of the case. For inefficient or intermittent resistance toughens clubfeet just as exercise strengthens normal muscles, ligaments and bones, but to a greater degree. Abnormal relations between bones induce abnormal shapes and abnormal internal structure. The correction of a clubfoot must be prompt and rapid to overtake the increasing rigidity. It must be excessive and long maintained, because of the inevitable tendency to relapse.

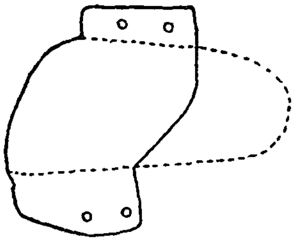


Fig. 1.—Pattern of footpiece. Dotted line shows outline of sole.

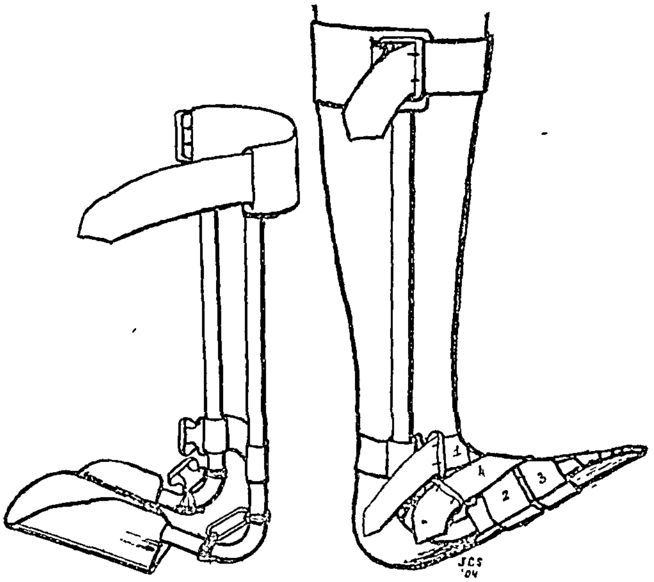
For the correction of the equinus in young subjects where the lateral deviation, if any, has been overcome, and where no operation is necessary, and also as a retention splint where the resistance to overcorrection has been eliminated by operation or otherwise, I employ the simple instrument here presented. Any tinsmith can make it from pattern and measurements furnished by the surgeon. It can be bent laterally as well as anteroposteriorly, into any required shape. It covers only those parts where pressure is needed. It has no joints to wear out. It is inexpensive. As compared with plaster of paris it has the following advantage: Being removable and capable of adjustment and modification, and the foot being accessible for examination, bathing, exercise and massage, one can apply more pressure than one would venture to use when the part is out of sight and reach. Rectification can therefore be more rapidly accomplished and nutrition is not so much interfered with.



Figs. 2 and 3.—Retention splint off and on.

The splint consists of a footpiece and calf band of galvanized iron or sheet brass, 22 gauge, and two side bars of telegraph wire, brass rod or Bessemer rod 3/16 inch in diameter. These dimensions are for a child of a year or under.

The footpiece is made from a tracing of the sole, as shown in Figure 1. It extends under the outer side of the sole sufficiently far back to make pressure on the cuboid and front of the os calcis. The posterior and inner parts of the sole are left uncovered so as not to interfere with the descent of the heel and arch. The footpiece extends upward on each side of the foot. If the foot is to be retained in a valgus position the inner lip is made higher than the outer.

The calf band is about 1¼ inches broad and extends half way around the limb posteriorly. It is placed as high as possible without interfering with the flexion of the knee.

The bars, being round, are pliable in any direction. They must be stiff enough to retain a given shape against the resistance of the foot. They are flattened at the ends where they are attached by two small rivets to the calf band and footpiece, and bent to the required angle of flexion. They should not be drilled except at the ends, because this would interfere with their modification.

Having made sure of the fit of the apparatus, it is covered and provided with straps and buckles. A piece of one-inch web long enough to encircle the limb with something to spare, and having a buckle attached to one end, is sewn or riveted to the outer face of the calf band, holes being punched for that purpose. The buckle is placed at the outer end. The whole splint, including the bars, is then covered with leather, or if that is not convenient, rubber plaster will serve, though it will require frequent renewal.

Cases of clubfoot present so much individuality that no hard and fast rule can be laid down for attaching the straps. Put them where they will be most effective and change them according to circumstances. In many cases of equinovarus, the following arrangement will be satisfactory: (Figures 2 and 3.) A heel strap of ¾-inch web is sewn from bar to bar so as to pass just above the tuberosity of the os calcis when the foot is at the maximum of flexion. This strap must be made shorter than needed, because it will stretch. A buckle is included with the outer bar. Another buckle is sewn to the outer bar just below it. A small iron or brass ring or a piece of wire with an eye in each end is secured to the inner bar at the bend. Starting at the upper buckle, a piece of web is passed across the instep (1) through the flattened ring, or under the wire, thence back (2) over the dorsum of the foot, and once (3) or twice (4) around foot and footpiece, to terminate in the lower buckle. The first turn draws the foot down within the grasp of the apparatus and holds the astragalus back under the tibia. The circular turns around foot and footpiece press down the inner border of the foot and correct the varus. Clayland of New York, as he states in a personal communication, starts the strap at the lower buckle and after bringing it back over the dorsum passes it through a slot in the sole plate near its outer edge, thence in a figure-of-eight turn around sole plate, inner side of foot, dorsum and outer ankle, within the bar, to a buckle placed at lower part of inner bar. This gives a lateral pull on the ankle. The instrument is worn over a stocking and inside of a shoe which has usually to be made to order. It may thus be used in walking and holds the foot in dorsal flexion and pronated or supinated if necessary. To evert the foot, the outer bar is extended up to a pelvic band, joints being provided at the knee and hip, and a band around the thigh.

Care must be taken that the heel strap does not stretch so that the foot plate slips forward and presses only on the metatarsals. The pressure should be exerted also on the cuboid and front of the os calcis.

Even after the foot has been allowed to assume a rectangular position for walking, it should be retained at night for a long time in a position the reverse of the deformity

As here presented, this apparatus is not suitable for use where the lateral deviation presents marked resistance. It is, however, susceptible of many modifications, such as the attachment of pressure plates to any part of the bars.

In reducing the strength of an acid by water the acid should be poured into the water, not the water into the acid, and the mixture should be stirred during the pouring.

AN X-RAY TUBE WITH ADJUSTABLE FOCUS

R. V. WAGNER, M.D.

CHICAGO.

If one examines the outline of a shadow from a light emanating from a large area—e. g., a gaslight—it will be seen to compare favorably with the outlines on a fluoroscope or on a picture, when the *x*-ray is used from a tube having the anode out of focus. On the other hand, the outlines of a shadow emanating from a small area—e. g., an arc lamp—resemble the outlines on a fluoroscope or on a picture, when an *x* ray tube having a sharply focused anode is used (Figs. 1 and 2).

The *x* ray emanates from the molecular bombardment of the rarefied air in the tube on the surface of the anode The structures of rarefied air are repelled from the concave disc or cathode forming the cathode rays or stream. This cathode stream striking the surface of the anode or disc in the center of the tube produces the *x*-ray. To obtain a sharp focus the anode must be a given distance from the cathode, just as an object must be a given distance from a lens to be in *focus.*

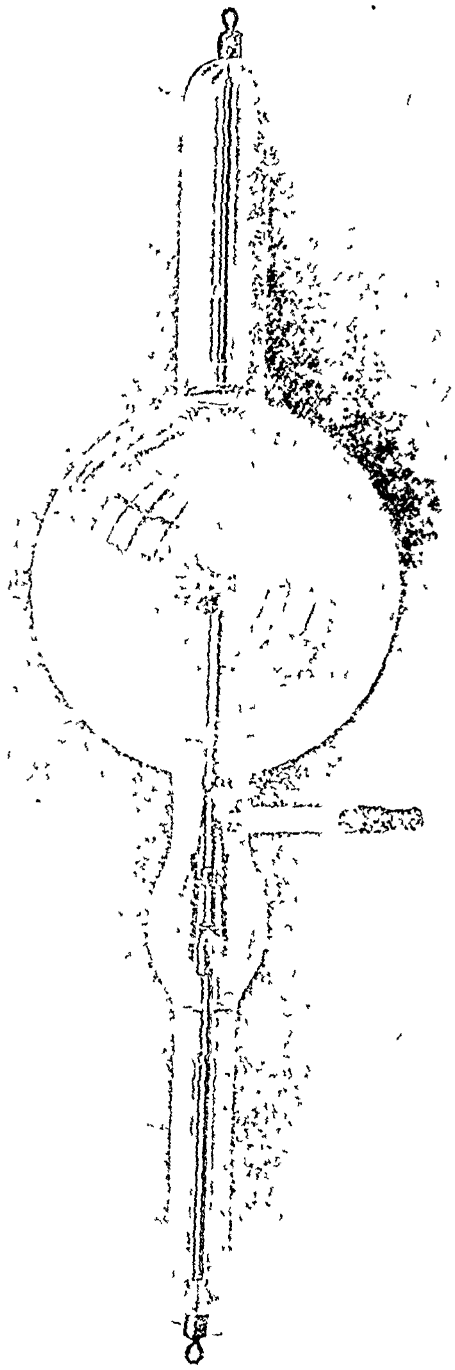


Figure 1

In making a Crookes tube by all methods used heretofore, it has been practically impossible to get the anode the required distance from the cathode, so as to obtain a sharp focus, as the stem supporting the anode had to be sealed in the glass by guess, and the tube exhausted before it could be tested, when if the anode was found defective in respect to its focus, it was too late to remedy the defect, without going to an expense nearly equal to that of making a new tube. A microscope can not be focused accurately by a person who guesses at the distance the lenses should be from an object, without looking through them. This would be much easier, however, than to focus a Crookes tube by guess, as to the distance the anode should be from the cathode, because of, the skill required on the part of the glass-blower to seal in the stem supporting the anode, so as to hold it where he thinks it should be; his judgment of where it should be is purely guesswork because there is no way of testing, until the tube is exhausted and properly excited

The new feature of my tube is in having the anode mounted on a threaded stem which can be magnetically operated through the glass, so as to move the anode up or down or circumferentially with the surface of the tube, to obtain an absolutely accurate focus (Fig. 3).

The little armature on which the magnet acts can not possibly get out of adjustment, and will hold the anode in any required position, either in focus or out of focus, as the operator may desire for some therapeutic purposes.

When a cheap metal is used for the anode, it must of necessity be out of focus because it will not stand up under the strain of having the molecular bombardment confined to a very small area, as is the case when the anode is in focus. Platinum is the only metal that will do for a sharply focused anode, as it not only stands a very high degree of heat, but is not broken down by the molecular bombardment, like inferior metals, e. g., nickel steel.

In my tube the anode (Fig. 4) is completely covered by a plate of platinum made very thick at the focus. This plate of platinum is electrically welded to the metal forming the body of the anode, and will stand an unusual degree of heat, and unlimited usage, even with the sharpest focus.

With my method of magnetically adjusting the anode, it is possible to make every tube alike, and to accurately focus the same after the tube is finished and in operation just as you focus a microscope by looking through the lenses, instead of guessing at the adjustment by observation as to the distance of the lenses.

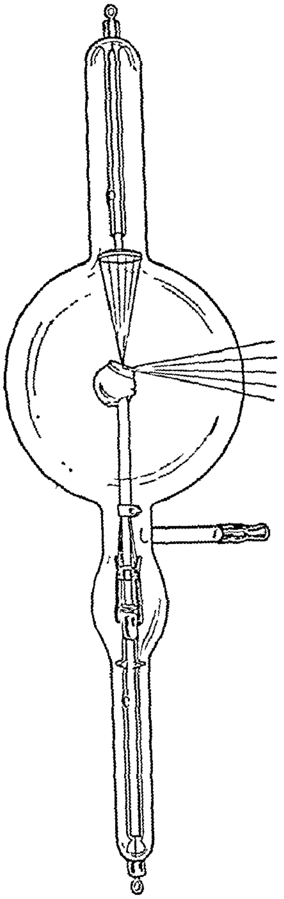

Figure 2

In order to appreciate the vast difference in x-ray work due to the proper focusing of a tube, the sharpness of definition can be carefully tested (Fig. 5) by taking an ordinary wire screen, 20 holes to the linear inch (called a 20-mesh sieve), hold the fluoroscope 24 inches away from a tube, and it will be found that with a poorly focused tube the screen will have to be brought very near the surface of the fluoroscope in order that the mesh be clearly distinguished. The nearer it is necessary to bring the screen to the surface of the fluoroscope, the more the tube is out of focus; but the farther away the screen may be held and the mesh clearly distinguished, the more accurate is the focus of the tube. With a perfectly focused tube the holes in a 20-mesh screen will stand out perfectly clear at least 12 inches away from the fluoroscope, having the fluoroscope 24 inches away from the tube.

A few simple tests that will enable anyone to distinguish a good tube from a bad one should be carefully considered X-ray workers posted on the requirements of a good tube will agree that it is more difficult to obtain a good tube to-day than it was a few years ago, before low-priced competition arose, and that two tubes made in appearance exactly alike, with practically the same degree of vacuum, and the same quality of glass for the bulb, will give entirely different results, on account of the difference in the focus effecting the definition in radiographic work. Every operator will find that out of a large number of tubes, as made heretofore, but one will do good work, and one that he is willing to adopt as his "pet tube."

THE SURGICAL USES OF RADIUM.

Much has been written and said during the past year about radium and its uses, and, as with every other new thing used therapeutically, there have been many sensational reports about remarkable cures. In a recent paper read before the Medical Society of the District of Columbia, Dr. Truman Abbe[1] gives an interesting review of the important work which has been done by investigators all over the world with radium, and also gives the results of some personal experience in its use. Metallic radium has not been isolated, and the product on the market and in general use is known as the chlorid of barium and radium. The strength or activity of a specimen is estimated by the rapidity with which the salt discharges a gold-leaf electroscope. The standard unit of time adopted is that required for the discharge of such an electroscope by metallic uranium. If the specimen of radium discharges the instrument in one-thousandth the time required by the uranium, the strength is taken as one thousand. Specimens of high strength are generally used, anywhere from two to three hundred thousand. The use of radium to give pictures of dense substances, as the x-rays are used, is not likely ever to prove very satisfactory, for it gives no sharp definition; the photographs are so blurred in outline as to have little value. Studies by a number of observers seem to show that radium rays diminish or inhibit the growth of certain forms of bacteria. Among others affected in this way are *B. anthracis, B. typhosus* and *B. coli communis*. Unfortunately the radium rays, like the x-rays, are not without harmful effects, so that the rays which inhibit the growth of bacteria damage the tissues to so great an extent that they probably will prove of little value. Radium burns resemble in nearly every respect those from the x-rays, appearing several weeks after exposure as a slight reddening, which, in case of longer exposure, may go on to form a blister or even a large ulcer. The scar is likewise smooth and hairless, even though the deeper parts of the skin are not involved, and healing is as slow as in x-ray burns.

The therapeutic uses of radium also follow the same lines as those of the Finsen and Roentgen rays. A number of cases of lupus treated successfully with radium rays have been reported. In some of these one part of the disease was treated with Finsen's light and the other with radium, with results in favor of the radium. Psoriasis and telangiectasis have also been treated successfully. One case of general melanosarcoma of the skin is reported by Exner of Vienna, in which the smaller nodules disappeared and the larger ones were growing smaller at the time of report. A large number of cases of inoperable and recurrent carcinoma and of epithelioma have been treated with radium, some of them apparently with considerable success. Exner treated a group of twenty cases in Gussenbauer's clinic with evident improvement in all. Cases of carcinoma of the cervix, and a case of inoperable carcinoma of the cervix and vagina, have been reported as successfully treated with radium. But too much confidence must not be placed in the value of radium therapy, and further study is necessary.

Newspaper reports—and even some articles in medical journals—about wonderful cures by radium, the x-ray or by other means undoubtedly do more harm than good. While too much should not be expected from any of those means of treating inoperable carcinoma, a sufficient number of cures have resulted to make their use entirely justifiable. Indeed, we believe that it is very unfortunate that so many members of the medical profession are inclined to neglect the treatment of inoperable malignant diseases. Such patients, if given no encouragement by the regular physician, are almost certain to fall into the hands of quacks, who not only extort from them all the money they can get, but almost invariably leave them in much worse condition than they were before. We can at least relieve pain, and give a little encouragement for permanent cure from the use of a number of the means which have been introduced from time to time. When operation is possible, it should certainly be given the preference in every case, and patients should be warned of the danger of temporizing with means of treatment, which are, in the majority of cases, only palliative.

The radium rays, no doubt should be classed with the x-ray, Coley's serum, Adamkiewicz serum and the various caustics. These have given cures in a few cases of inoperable malignant diseases, but they are too uncertain in their action to be used except when operation is out of the question. No doubt in the future we may be able to determine the cases to which these various therapeutic measures are best adapted, and the number of cures by such means may be considerably increased. It is along these lines we believe that radium will prove most useful.

ARTERIOSCLEROSIS.

The changes in the blood vessels are important accompaniments of senility. Whether these begin in the one coat or in the other, they give rise to loss of elasticity and reduction in lumen, so that the tissues are less well than normally supplied with blood, which, in addition, may be deficient quantitatively and qualitatively. The result is a condition of impaired nutrition, which by reason of the nature of the underlying disorder is insidious in onset and progressive in course. The alterations in the vessels, while as a rule widespread, are not always uniform in distribution, either in extent or in degree, and the sequels to which they give rise vary correspondingly.

---

[1] Washington Medical Annals, 1904, vol. ii, page 363.

A number of interesting points were brought out in a discussion of this most important topic held recently before the Pathological Society of London.[1] Dr. T. D. Savill defined arteriosclerosis as a chronic, generalized thickening, condensation or degeneration of the arterial walls, which become hard or less elastic than normal, while the lumen remains unduly patent after death. He distinguishes three varieties, namely, intimal, medial and adventitial. The first and the third are often secondary to disease of the muscular coat. Atheroma, a patchy fibrocellular infiltration of the intima, is to be considered as distinct from intimal sclerosis. From a study of the bodies of 400 persons dead at the age of 60 years and upward, Dr. Savill reaches the conclusion that extensive patchy atheroma is consistent with extreme longevity and with a total absence of symptoms or vascular complications, and that the same statement is applicable to marked generalized intimal and adventitial sclerosis, provided that the media is relatively free from hypertrophy or disease, and that the balance between the heart and the arteries is not materially disturbed. On the other hand, he considers moderate disease of the muscular coat a serious potential evil. This may take the form of atrophy, which is not common, but is found in association with some wasting diseases; hypertrophy, which is more common, especially after middle life; cloudy swelling, with which granular degeneration is frequently associated; necrosis and calcification, occurring in spots or foci of varied size.

The term arterial hypermyotrophy is employed to describe a condition characterized by a generalized increase in the thickness of the muscular coat of the arteries due to an increase in volume, with or without numerical increase of the individual muscular fibers. It is a condition of genuine muscular hypertrophy, although it may be succeeded by degeneration. At an early stage it is relatively uncomplicated by other arterial disease, while later intimal and adventitial sclerosis and degeneration are likely to be present. The condition may be secondary to chronic renal disease, but often it occurs independently of such disease. It is, as a rule, associated with hypertrophy of the heart, either as cause or as result, or as the product of a cause common to both. The blood pressure is high, and the condition of the vessel-way may be responsible for hemorrhage into the brain and other situations.

Dr. Clifford Allbutt recognizes three varieties of arteriosclerosis, namely, toxic, as from lead, infectious diseases, diabetes, etc.; involutionary, from senile degeneration; and secondary, from arterial hyperpiesis. The first and the second are not necessarily attended with increased arterial pressure, on which the third is essentially dependent. The second and third may be present together, but are not so as a rule. In the second calcification is more likely to occur and all of the coats of the artery may be involved, but the heart is little if at all hypertrophied or dilated. In the secondary variety the first apparent factor is an increase in arterial pressure, probably dependent on some alteration in the blood and this in turn on some perversion of metabolism.

Dr. J. F. H. Broadbent includes under the term arteriosclerosis the degenerative lesions of the aorta comprised under atheroma, as well as those of the smaller vessels, on account of their close etiologic and pathologic relations. In a study of the vascular changes in sixteen cases of cerebral hemorrhage, senile degeneration of the vessels was found in two, while seven were associated with granular kidney and seven with a type of kidney in which the most characteristic changes were thickening and hyaline degeneration of the inner coat of the vessels. In the latter fourteen cases the heart and the middle coat of the radial artery were greatly hypertrophied. The cerebral vessels were dilated, thinned and hyaline, or studded with small white patches, which on microscopic examination were found to consist of localized thickening and degeneration of the subendothelial tissues, over which the muscular coat, thin and atrophied in some instances, could not, as a rule, be traced. In four cases there was advanced atheroma of the aorta; in the remainder slight degenerative changes immediately above the aortic valves or no change appreciable to the naked eye. Of six cases in which the coronary arteries of the heart were examined they were found healthy in four and in a state of advanced degeneration in two. The principal clinical characteristics were high arterial tension, hypertrophy of the heart and in several instances albuminuria. The high arterial tension was attributed to increased peripheral resistance, as a result of tonic contraction of the arterioles and capillaries, due to toxic substances circulating in the blood, perhaps from imperfect elimination on the part of the diseased kidneys. In the second group of cases the high arterial tension is believed to have antedated by many years the disease of the kidneys, and the toxic substances, such as lead and the products of deranged metabolism, that induce hypertonicity of the peripheral arterioles also give rise to the thickening and the degenerative changes in the renal vessels. The increased peripheral resistance causes hypertrophy of the heart and the muscular coat of the systemic arteries, and this is not to be regarded as a disease, but as a response to increased work. The cerebral vessels, however, being poorly provided with muscular tissue, become dilated under the constant and increasing pressure; their nutrition is interfered with; thickening and degenerative changes occur in the subendothelial tissues; the muscular coat becomes atrophied over the bulging necrotic tissue; and rupture frequently occurs. This type of degeneration, common in the aorta and the cerebral vessels, is not met with in the kidneys, in which thickening and hyaline degeneration of the intima and adventitia and hyaline degeneration of the glomeruli are the most characteristic lesions. The toxic products in the circulation are thought to be the predominant factors in causing vascular degenerations in the kidneys, while high arterial tension is considered as mainly responsible for lesions in the cerebral vessels. Intermittent strain associated with arduous occupation is doubtless responsible in many instances for the degenerative changes in the aorta with which aneurism is so frequently associated. Syphilis is an important etiologic factor in a large number of cases. Microscopically obliterating endarteritis of the vasa vasorum will be found, causing localized areas of necrosis in the vessel wall as a result of imperfect nutrition.

---

[1] The Lancet, Feb. 20, 1904, p. 506.

With a knowledge of the facts at hand the problem presented to the clinician is the removal of influences causing increased arterial pressure and the reduction of this pressure to the normal, and also the elimination of toxic matters circulating in the blood, apart from prophylactic measures directed to the avoidance of these conditions. Hereditary influences must receive consideration in this connection and special precautions must be taken by those in whose families arterial degeneration is known to occur.

THE TYRANNY OF WORDS IN MEDICINE.

In his recent volume of lectures on diseases of the nervous system, in the course of his description of a case that he found labeled on the bed card of his clinic "simple neurasthenia," though on the gums of the patient he found a conspicous lead line, Sir William Gowers has something to say of the word neurasthenia and of other words that may cover symptom-complexes, for which it would be much better if the physician should find more definite terms. He says:
